As we have said, an ordinary incandescent lamp will do as a gauge; but it is even simpler (and for various reasons preferable) to use the same lamp before it is evacuated and with the pumping stem still attached. Probably any lamp maker would supply such lamps; if they are obtained from these laboratories, they will be furnished with a rough calibration—a calibration as good as that which the McLeod usually receives.

Zoological Bibliography.

I AM desired by the Corresponding Societies' Committee of the British Association to direct attention to the Report of the Committee on Zoological Bibliography and Publications, which was presented at the Liverpool meeting of the Association, and to ask those interested in the publications of scientific societies earnestly to consider the recommendations made by this Committee, and thus avoid the unnecessary confusion and difficulties which arise from thoughtlessness rather than ignorance.

There are many important points to be borne in mind, particulars of which can be seen in the Report of the Committee, which can be obtained from the Secretary of the British Association, Burlington House, Piccadilly, W.1, but those to which particular attention is desired are: (1) The size of the publication, which should be demy-octavo (that is, the size of the Reports of the British Association); (2) that each part issued should bear the actual date of publication; and (3) that the titles of papers should, so far as possible, give a fair idea of the contents of the papers, and be brief.

A New Method of Crystal Powder Analysis by X-rays.

FOR the purpose of enabling us to make more accurate comparative intensity measurements by the photographic powder method, and also of obtaining sharper lines without recurring to long exposures, an arrangement has been tried in which a thin layer of powder and a beam of greater angular width are used.

Modifications of the original arrangement of Debye and Scherrer and of Hull making use of wide beams have been described by H. Seemann, by H. Bohlin, by Sir William Bragg, and by the writer.[1] It has in particular been shown by Sir William Bragg, that by his arrangement, which involves the use of the ionisation method, it is possible to make not only rapid

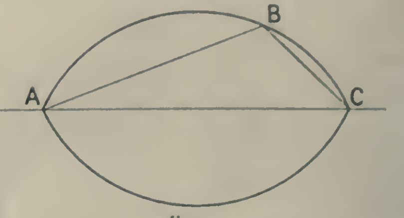

FIG. 1.

but also very accurate determinations. The present arrangement is intended to correspond to the peculiar conditions of the photographic record.

A short reference to the general conditions of reflection may take the place of an extended discussion. The geometrical locus of all crystal powder particles, which are so situated that rays reflected by them from A to C (Fig. 1) suffer the same deflexion α, is that surface of revolution described by the rotation of the arc of a circle ABC subtending the angle $\pi - \alpha$ on the chord AB. This surface has a different shape for each angle of deflexion α.

To obtain simple conditions for a quantitative interpretation of the reflected intensities the writer had used (*loc. cit.*) an equatorial annular band of this

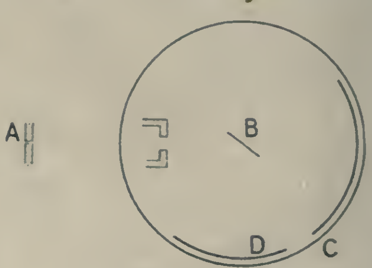

FIG. 2.

surface in conjunction with a point source of X-rays. At present in order to obtain lines which are more suitable for exact angular measurement, only a small area round B is used in connexion with a line source. The line source allows us to make more efficient use of the radiation of the anticathode and partly compensates for the decrease in angular extension of the beam.

Fig. 2 represents the arrangement adopted. A is the line source of X-rays situated close to the anticathode, B the powder layer, which can be rotated about an axis parallel to the source, and C is the film on which the lines are recorded. According to the geometrical relations given above, to every angle of deflexion, *i.e.* to every point on C, there is associated

[1] H. Seemann, *Ann. d. Phys.* 59, pp. 455-464, 1919; H. Bohlin, *Ann. d. Phys.* 61, p. 421, 1920; Sir William Bragg, Proc. Phys. Soc. 33, p. 222, 1921; J. Brentano, *Arch. Sc. Phys. et Nat.* (5) 1, p. 550, 1919.

a definite orientation of the powder layer at B, which corresponds to the orientation of the surface of revolution and vice versa. In order to record the lines over an extended angular region a screen D has therefore to be provided with an opening, which for any particular position of B uncovers only the corresponding portion of C. The screen has to be moved with uniform angular velocity and B has to take the corresponding required positions. If we call β_1 and β_2 the glancing angles of incidence and of emergence at B then $\frac{\sin\beta_1}{\sin\beta_2}=\frac{AB}{BC}$ and $\beta_1+\beta_2=\alpha$ is the angle of deviation. The relation between the motion of the screen and of the powder layer becomes the simple spectrometer relation when AB equals BC, but this arrangement is not the most efficient for obtaining beams of greatest specific intensity. With the setting corresponding to a given resolving power the time of exposure will depend on the angular width of the region explored. The method is most efficient for exploring small angular regions for the exact measurement of a few characteristic "key" lines, but owing to the gain in intensity by using wide beams there is some saving of exposure also for more extended surveys.

A fuller discussion of the method and description of the apparatus used will be given elsewhere. With a small camera of this type, BC being 2·3 cm., a photograph was taken of the first order reflection of CuK radiation from the 111 and 100 faces of nickel oxide with 1·2 milliamp-hour exposure, the angular extension of the region recorded being about 20°. The lines were less than 0·1 mm. wide and their centres could be evaluated to 0·03 mm. When the greatest possible intensity is required for tracing faint lines in a narrow angular region, a powder layer of suitable curvature which allows us to use beams of considerable angular width is of advantage. For quantitative measurements, where the absorption under different angles of incidence has to be taken into account, and for exploring wider angular regions, a flat surface is more suitable. By exposing it from different sides, errors due to eccentricity in mounting can then be eliminated. This procedure was used in the case of the nickel oxide mentioned. J. BRENTANO.

A Large Sarsen Stone.

A SARSEN stone of unusual size, for this district, has recently been found in the gravel pit belonging to the Hounslow Sand and Gravel Co., and through the courtesy of the manager, Mr. Ralph Wallis, I have been permitted to pay several visits for purposes of investigation and photography.

In section, the pit shows:

Soil	1 ft.
Indurated mud, like warp .	1 ft. 6 in.
Loamy gravel, penetrated by the warp (averages) . .	7 ft.
"Clean" gravel and sand .	8 to 21 ft.

resting on London Clay of unknown thickness.

The sarsen (Fig. 1) was found embedded to the depth of 1 ft. in the London Clay with several others of much smaller size—from a few lb. to about 2 cwt.—and they were the only ones found there. It is computed to weigh 6 or 7 tons, but owing to the number of tubular cavities present, varying in length from a few inches to 3 ft., and in diameter from $\frac{1}{16}$ to 2 in., even an approximate computation may have to be considerably revised. Its maximum height, as now standing, is 5 ft. 7 in., maximum thickness 1 ft. 11 in., and its maximum width 5 ft. 7 in.

There are several interesting details which might occupy too much space to describe here, but perhaps I may be permitted to refer to the cruciform surface-feature conspicuous in the photograph of the surface which was uppermost when the block was *in situ*. It is due to the fact that two of the long, tubular cavities cross each other in the heart of the stone, this being rendered visible through the erosive action of falling

FIG. 1.—Sarsen stone from London Clay.

water, at some time or another, forming a basin-shaped depression, 4 ft. in diameter and 7 in. deep, which has exposed the internal structure. There is little doubt but that the tubular cavities have also been considerably enlarged and modified by the action of running water. A few striations on one of the faces strengthen the assumption of its association with ice-action. The rock is of the usual type—a very hard siliceous sandstone, white within and stained externally by contact with ferruginous water.

Dr. Kammerer's Ciona Experiments.

IN NATURE of May 12, p. 639, Dr. Kammerer wrote: "Not content with any of the previous experiments [made by himself on the inheritance of acquired characters], I carried out, before 1914, what may really be an *experimentum crucis*," and Dr. Kammerer states that when the siphons of *Ciona intestinalis* are cut off they regenerate longer than they previously were, repeated amputations giving very long tubes, and that the offspring of these individuals have siphons longer than usual.

I repeated these amputation experiments between June and September last at the Roscoff Biological Station. The oral siphon was removed from 102 *Ciona intestinalis* which were growing attached to the walls of the tanks. The animals varied in length from 0·9 to 4·8 cm. As controls, 235 unoperated individuals were kept under observation. In none of the operated animals was there any further growth of the siphons after the original length had been re-attained.

One operation was performed on 59 individuals, two on 35, and three on 8. The time necessary for

the re-attainment of the original siphon-length depended on the level at which the cut had been made: it varied from 14 to 44 days, with an average of 27 days. The animals operated upon once were kept under observation from 22 to 61 days after the original siphon-length had been re-attained, the average period being 42 days; those operated twice for an average of 34 days; and those three times for 27 days after the last re-attainment of the original siphon-length. In none of the operated animals did any further growth of the siphons take place after the original dimensions had been reached.

After this negative result of the preliminary experiment it seemed useless to try Dr. Kammerer's further operation of removing the gonads from the animals with re-grown siphons, allowing other gonads to regenerate, and then breeding a second generation.

In 1913 it was shown at Naples that abnormally long siphons of *Ciona intestinalis* can be grown by keeping the animals in suspensions of abundant food (*Biol. Centrbl.* 1914, vol. 34, p. 429). Were this the reason for the long siphons of Dr. Kammerer's operated *Ciona*, it should have been clear from controls of unoperated animals kept in the same water.

A full account of the work at Roscoff will shortly be published in the *Journal of Genetics*.

Selective Interruption of Molecular Movements.

I WAS somewhat surprised to see that in spite of Mr. Atkinson's letter, Mr. Fairbourne, in NATURE of July 21, still endeavours to maintain his view that the relative gas-pressure in two communicating vessels at equal temperature depends upon the shape of the channel joining them, provided the pressure is sufficiently low. The proper method of treating the question, which of course does not lead to such an extraordinary result, may be found in any text-book on the kinetic theory, and it might have been expected that Mr. Fairbourne, before claiming to prove a paradox of this sort, would indicate in what way the usual treatment is wrong. Instead of doing so he adopts a curious treatment of his own, in which he shows that in certain circumstances more paths lead into one vessel than into the other, without considering that the number of molecules which enter either vessel in unit time depends not only upon the number of such paths but also upon their length. When this is taken into account the usual result is obtained, namely, that the pressure in the two vessels is equal whatever the shape of the channel between them.

Effects of Anæsthetics on Plants.

ANÆSTHETICS are known to cause alterations in the permeability of cells to the ions of various salts. It can be shown directly, by using the corolla of *Ipomœa Learii*, that the permeability of plant cells to carbon dioxide is also altered by anæsthetics.

The corolla consists of two layers of cells only, with thin cuticle, no intercellular spaces, no stomata. The cell-sap contains an anthocyanin, which indicates P_H (thus avoiding complications due to an added indicator). The buds are pink (P_H 6), changing to full blue (P_H 7·8) as the flower opens, in 30-40 minutes. The blue changes through violet to pink as the flower withers (6-8 hours). Portions of the blue corolla floated on water saturated with carbon dioxide rapidly turn pink: this change is reversible on removing to plain water.

If discs cut from the corolla are first treated with aqueous solutions (0·04M-0·1M) of chloroform or ether, and then with a saturated solution of carbon dioxide (P_H 5), a time-curve can be constructed, showing the changes in permeability to carbon dioxide induced by varying exposures to the anæsthetics.

The first effect is a marked decrease (often as much as 50 per cent.) in the rate of penetration of carbon dioxide into the cell, the decrease lasting 10-15 minutes; the rate then increases rapidly, reaching 200 per cent. in 40 minutes, and continuing to increase. After 40-50 minutes' exposure to the anæsthetics the tissue becomes irresponsive.

In order to reach the cell-sap the carbon dioxide must pass through (1) the cell-wall, (2) the protoplasm lining the cell-wall. The fact that the cells of the disc change colour simultaneously shows that the carbon dioxide passes freely through the wall. On the other hand, hydrochloric, sulphuric, and acetic acids of the same P_H as the carbonic (P_H 5) penetrate only from the cut edges of the discs inwards, and not over the whole area. The addition of ether or chloroform to these acids has a similar effect on their rate of penetration into the cell as on carbonic acid. It is therefore concluded that ether and chloroform alter the permeability of the plant cell to carbon dioxide by their action on the protoplasm and not on the cell-wall.

These alterations in permeability to carbon dioxide may affect the *apparent* rate of respiration (measured as carbon dioxide output) under anæsthetics, and a suitable correction may require to be made in such experiments.

Stereoisomerism among Derivatives of Diphenyl.

THE references to Dewar's formula for benzene which are made in the letters of Dr. Turner and Dr. Kenner in NATURE of September 22 and October 13 (pp. 439 and 539) raise a point of some importance in regard to the use of symbols in chemistry. Sir William Bragg's work has revealed the fact that the length of the carbon-to-carbon bond is remarkably constant at about 1·5 Å.U. Dr. Turner, however, following the common convention, represents the para-linkage in his formula for diphenyl by a bond which is perhaps twice as long as those joining adjacent atoms in the ring. It is, of course, possible to maintain the normal length of the bond by distorting the benzene hexagon into a quadrilateral, thus,

```
    H
HC—C—CH
 ‖  |  ‖  ;
HC—C—CH
    H
```

but there is, I believe, no indication whatever of any such extreme distortion in Bragg's work on the X-ray analysis of crystals of aromatic compounds. This difficulty would not arise if the para-linkage were regarded as indicating only the existence of "free affinities" on the 1 and 4 carbon atoms, or of an electrovalency between them; but so long as this link is treated as a real bond, there does not seem to be any justification for stretching it to an abnormal length, although this is clearly necessary in order to preserve the very well founded idea that the benzene-ring is fundamentally hexagonal in form.

The Origin of Optical Spectra.

AMONG the many remarkable communications made this year to Section A (Mathematics and Physics) of the British Association, which, grouped together, will probably mark it off as an outstanding meeting, the address by the sectional president, Prof. McLennan, on the origin of spectra, was not the least interesting. From among the many subjects he surveyed it may be of interest to select some, and to try to give a not too technical account of these, showing the sort of progress that is now being made under the stimulus of Prof. Bohr's theory.

We agree now that all spectra are emitted by atoms or molecules during the process of return to their normal state after a more or less violent disturbance, and that any particular spectrum is emitted only by a particular atom or molecule after a suitable disturbance. We agree too (partly for theoretical, partly for experimental reasons) that spectra can be divided into two distinct types—line spectra or series spectra and band spectra or many-line spectra—which have their origin in the reconstruction of atoms and molecules respectively. It is with recent advances in the more advanced and more important study of these atomic or line or series spectra, emitted during the reconstruction of atoms, that the president dealt, and with these only shall we be concerned here.

Physicists will agree that an atom consists of a very small massive nucleus of positive electric charge Z units, the unit being the charge on the electron, surrounded by a planetary system of Z electrons. These move, when undisturbed, as a conservative system in a set of orbits which must have a definite structure, controlled by laws of which we are not yet masters, to which, however, the present quantum theory gives the most complete expression yet achieved. The number Z is called the atomic number of the atom, and specifies its place in the periodic table and all its physical and chemical properties. We can agree further that the orbits of the Z electrons are not all essentially different. They can be classified in groups, orbits of which are characterised by the same values of certain integers (three to each orbit), commonly called quantum numbers.

There are a variety of disturbances to which such an atom can be subjected. By suitable means supplying sufficient energy we can shift one or more of its electrons from their normal orbits, either right out of the atom, or into other possible orbits characterised by different quantum numbers. In the subsequent reconstruction the atom will emit a spectrum of sharp lines of definite frequencies characteristic of itself and the particular disturbance it has suffered. Each separate line is emitted during the return of an electron from one particular permissible orbit to another of less energy, and its frequency is related to these orbital energies by the most fundamental equation of the quantum theory $E_1 - E_2 = h\nu$. After the partial removal of a particular electron we merely get part of the spectrum corresponding to complete removal of the same electron. We can therefore, speaking generally, classify the complete line spectrum of a given atom into a number of separate spectra, each of which is associated with the recapture of one electron by an atom after the removal of any specified set of its original Z electrons. Classified thus, an atom's spectra will divide into two well-marked types—those in which one or more of its deeper lying electrons have been removed and those in which the electrons removed, whatever their number, are entirely those most lightly bound. In the first type we can and do find internal reorganisations taking place before a new electron is captured. These are the X-ray spectra, with which we are not here concerned. In the second type no such reconstruction can occur, except while the new electron is being brought in. These spectra, which theoretically must all be of the same general series type, are called the optical spectra of the atom.

The typical optical spectrum (the so-called arc spectrum) of an atom is agreed to be that which is emitted during the return of the last (Zth) electron to an atom in which the rest of the system is in its normal state. When such a spectrum is fully analysed it is found that the lines can be arranged in series which display a certain fundamental constant R, Rydberg's constant. The value of this constant and its perpetual occurrence in all arc spectra is (as is well known) properly predicted by the theory. But this is not all. If we call the ordinary arc spectrum Z(I) and its Rydberg's constant R, the theory we have outlined predicts Z optical spectra in all, of which the Qth spectrum Z(Q), with constant Q^2R, will be emitted by the atom with its first $(Z-Q)$ electrons in their proper orbits as it catches its $(Z-Q+1)$th electron. The characteristic *frequencies* of these spectra will, of course, get higher and higher as Q increases, and for the later "optical" spectra of a heavy element will lie in the X-ray region. It is not the frequency range but the *type* of spectrum which remains characteristically optical.

The predicted second optical spectra Z(II), with Rydberg constant 4R, have been known for some years for a number of elements, under the general name of spark spectra; until recently we have had no experimental confirmation for values of Q greater than 2. In the last year there has been a great advance, for the third optical spectrum of aluminium with constant 9R has been obtained by Prof. Paschen, and the fourth and parts of the third optical spectra of silicon with constants 16R and 9R respectively by Prof. Fowler. These spectra are known by the very convenient notation of Al III, Si IV and Si III. It will be seen that the spectra Si IV, Al III, Mg II and Na I are all concerned with the capture of the eleventh electron by an atom (of varying Z) which has already bound its first ten electrons in their permanent orbits. These four spectra should be and are of the greatest similarity in their finer details. Their further detailed comparative study should be fruitful.

Prof. McLennan also pointed out that this successful study should throw light on the various optical spectra of the analogous series of elements, lithium, beryllium, boron, and carbon. In this difficult and very important region little progress has hitherto been made, but Prof. McLennan seemed hopeful that, with the theoretical and comparative guides now available, a renewed

attack would be successful in completing and classifying these spectra.

These are the broad outlines; let us now turn to finer details. It is well known that the theory, though it gives us general information about all optical spectra, so far can only predict in all its finer details the spectrum due to the binding of the first electron. The only spectra of this type yet experimentally realised are what we may now call H I and He II, that is, the spectrum of atomic hydrogen of which the most conspicuous feature is the well-known Balmer Series, and the spectrum of ionised helium. Now the predictions of the theory not only give the exact position of each line, but, as is well known, also assign to each line a definite complex structure. Under very high dispersion and first-class conditions this structure can be observed. In the case of He II, where the separations are greater and the conditions less severe, the confirmation of the theory was completed some years ago by the photographs of Prof. Paschen and others. Until recently, however, the similar more difficult experiments for the Balmer Series have been inconclusive and discordant. For this series the theory demands that each line should split into two close lines of the same frequency difference, which should themselves have a still finer detailed structure. Into this we need not enter, beyond saying that this ultimate structure should slightly reduce the apparent separation of the lines of longest wave-length, particularly H_α. Now the last lacuna has been filled by a brilliant piece of work in Prof. McLennan's laboratory, for good photographs have been obtained showing clearly the main separations of the five lines of longest wave-length. The agreement with the theory is complete. To illustrate the fineness of the detail it may be mentioned for example that for the fourth line H_δ, wave-length $4101 \cdot 73 \times 10^{-8}$ cm., the theoretical main separation is only $6 \cdot 1 \times 10^{-10}$ cm.

It has been known for some time that the energy required to remove one electron from neutral helium was (in the usual terminology) about 25 volts. We thus express the energy acquired by an electron in falling freely through such a potential difference. Thus expressed the energy required to remove the most lightly bound electron is known as the ionisation potential. Until recently the known part of the spectrum He I made no allowance for a normal atom in which the electrons were so firmly held. It appeared that these ought to be a series of lines in the far ultra-violet, not hitherto observed, associated with the reconstruction of the normal atom. Four such lines have now been observed by Lyman. The wave-lengths are very short, from 500 to 600×10^{-8} cm., and indicate an ionisation potential of $24 \cdot 5$ volts, in good agreement with direct observation. Our experimental knowledge of He I is thus properly rounded off. Much valuable work on the theory of this spectrum has also been completed, but the results are negative. It is now certain that none of the models so far proposed possess the proper permissible orbits, computed according to the rules of the present quantum theory, to account for the spectrum He I and the ionisation potential. It is an advance to be sure of this. The interaction of the two electrons in helium (and *a fortiori* the Z electrons in the general atom) must be even more subtle, and the *detailed* theory of their orbits must lie even deeper, than has been hoped hitherto.

Recent work has shown the very great value of the study of the absorption spectra of atomic vapours in the coldest state in which they can be procured at reasonable densities. Such vapours, as is well known, absorb selectively a number of sharp lines which are a selection of the lines of the first optical (emission) spectrum. But since the atoms of the vapour must in general be in their normal state, only those lines can appear which belong to atomic reconstructions ending in this normal state. We can thus select from the whole mass of lines just those associated with one particular state of the atom, and that the most important. In this way certain difficulties have been cleared up in connexion with the spectrum Al I and its analogues. It had been believed that the normal orbit of the most lightly bound electron was of the same type for all atoms—that is, specified by a certain value (unity) of one of its quantum numbers. This is the theoretical interpretation of the empirical belief that the absorption spectrum would always consist of the same type of series. But the known facts about this group of spectra did not fit in with this belief, and it is now definitely established by the study of absorption spectra that this belief is false. The normal orbit in question may have at any rate one or two for the value of this quantum number, and has the value two for aluminium and its analogues. Thanks to this we now know that our account of these spectra is reasonably complete. The study of absorption spectra will doubtless prove of great value in disentangling the difficult spectra of the lead-tin group. A good start has recently been made in their classification.

Let us with Prof. McLennan conclude by referring to the effect of an applied magnetic field on the atomic orbits, with which is bound up the question of the way in which the atom orientates itself in space under such an influence. The effect on the spectrum is known as the Zeeman effect, and its study is proving of the utmost importance to the theory of atomic structure. It is here that we shall probably win the next advance. We can scarcely expound these questions shortly and cannot enter into details here. But it may be said that the proper classification of the empirical facts, largely the work of Prof. Lande, seems already fairly complete, and that their theoretical interpretation has been begun on a sure basis. We must not, however, omit to mention the cognate beautiful experiment of Stern and Gerlach, which consists in directing atoms of silver of known velocity through a strong non-uniform magnetic field. If the atom possesses a magnetic moment it must be deflected, unless its axis is always perpendicular to the field. Such deflexions were observed, and appear to prove, simply and directly, that the normal free atom of silver possesses a definite magnetic moment and always sets itself with its magnetic axis parallel or anti-parallel to the field. Experiments such as these are of the greatest importance. They admit of unambiguous interpretations and provide the necessary strong points from which the attack on the complicated Zeeman effect and related phenomena can be securely launched.

R. H. FOWLER.

Symbiosis in Animals and Plants.[1]

By Dr. GEORGE H. F. NUTTALL, F.R.S., Quick Professor and Director of the Molteno Institute for Research in Parasitology, University of Cambridge.

I. SYMBIOSIS IN PLANTS.

(1) *Lichens.*

IT is well known to botanists that the vegetative body (thallus) of lichen plants consists of two distinct organisms, a fungus and an alga ("gonidia"). Schwendener (1867–69) regarded the fungus as living parasitically upon the alga, a view which gained support from subsequent researches, especially those of Bonnier (1886–9), wherein synthetic cultures were obtained by bringing together (*a*) various algæ and (*b*) fungus-spores isolated from cultures of fungi forming the one component of certain lichens.

The long and apparently healthy life of the associated fungi and algæ led de Bary (1879) to define the condition as one of *symbiosis*, the term denoting *a condition of conjoint life that is more or less beneficial to the associated organisms or symbionts.*[2]

Investigation has shown that the relation or balance between the associated organisms varies in different lichens; in some the partners inflict no injury upon each other; in some, occasional parasitism of the fungus upon the alga is observable. Elenkin (1902–6) and Danilov (1910) take it as proved that lichens owe their origin to parasitism, the fungus either preying upon the alga or living as an "endosaprophyte" upon the algæ that die.

Therefore we may find in lichens the condition of true symbiosis on one hand, ranging to demonstrable parasitism on the other, and, conversely to what has been described above, examples are known wherein algæ are parasitic on fungi (Beijerinck, 1890).

The nutrition of algæ in lichens is similar to that of other chlorophyllaceous plants, the most important work on the subject being that associated with the names of Beijerinck (1890) and Artari (1902). The algæ associated with fungi in lichens are placed advantageously in respect to nitrogen supply. The important researches of Chodat (1913) have demonstrated that cultivated gonidia develop four times as well when supplied with glycocoll or peptone in place of potassium nitrate.

The gonidia lead a more or less saprophytic life in that they obtain from the fungus-hyphæ both organic nitrogen and carbon in the form of glucose or galactose. The nutrition of fungi in lichens depends partly upon parasitism, when they invade the gonidia, and partly upon saprophytism, when they utilise dead gonidia (Chodat). M. and Mme. Moreau (1921) regard the fungal portion as a gall-structure arising from the action of the associated alga. The lichen, according to this view, is to be regarded as a fungus that has been attacked by a chronic disease which has become generalised and necessary for the subsistence of the host-fungus.

[1] From the presidential address delivered to Section I. (Physiology) of the British Association at Liverpool on September 13.

[2] Bacteriologists are continuously misapplying the term symbiosis in referring to bacteria grown in mixed cultures, when there is no evidence whatever that the micro-organisms are mutually interdependent for their growth.

(2) *Root-nodules.*

A well-known example of symbiosis is afforded by the presence of the bacteroids in the nodules of Leguminosæ, the micro-organisms being capable of fixing atmospheric nitrogen and thereby rendering nitrogen available for assimilation by the plant. Nodules on the roots of the alder are attributed to the presence therein of Streptothrices, and comparable nodules occur in Eleagnaceæ. The nodules on the leaves of Rubiaceæ and tropical Myrsinaceæ are also regarded as due to bacterial symbionts.

(3) *The Significance of Mycorhiza in Relation to Various Plants.*

The roots of *most perennial and arborescent plants* are invaded by the mycelium of fungi known as Mycorhiza, and according to hypothesis we are here dealing with symbiotic life. Frank distinguishes two forms of Mycorhiza: (1) the ectotrophic, which surround the root externally (found especially about the roots of forest trees), and (2) the endotrophic, which penetrate deeply into the root tissue and its cells. The fungus utilises the reserve substances stored in the cell. The intracellular mycelial mass after a time undergoes degeneration, is digested by the host, and the host-cell resumes its normal life. Further details regarding these fungi will be found in the paper of Gallaud (1904).

Mycorhiza in Orchids.—The first to note the presence and to attempt to cultivate the fungus mycelium in the roots of orchids was Reisseck (1846), and in 1881 Kamienski advanced the hypothesis that the association was one of symbiosis. Wahrlich (1889) subsequently found symbionts in all species of orchids he examined, about 500 in number, thereby showing that their distribution is generalised. It is to the researches of Noël Bernard (1902 onward), however, that we are actually indebted for the complete demonstration of the true relation existing between orchids and Mycorhiza, based as it is upon physiological studies.

The essential discovery of Bernard was that orchid seeds do not germinate in the absence of fungi belonging to the genus Rhizoctonia. Each species of orchid, according to the subsequent researches of Burgeff (1909), possesses a special species, variety, or race of fungus that is particularly adapted to it—he distinguishes fifteen species of fungus. The fungus mycelium, having attained the parenchyma cells, develops into characteristic filamentous masses recalling the appearance seen in bacterial agglutination. After a time, the development of the fungus is arrested by the deeper parenchyma cells of the seeds. These digest the mycelium, but the cell continues to harbour remains of the fungus ("corps de dégénérescence") which occur abundantly in the tissues of orchids. The seed now proceeds to sprout, giving rise to a small tubercle, which at a later period produces leaves and roots. The cultivation of Rhizoctonia of various species was carried out successfully by Bernard, the cultures being used to reproduce germination in orchids.

The relation between the fungi and orchids varies in different groups of these plants. In some cases symbiosis is intermittent, in others continuous. In *Neottia nidus-avis* the symbiotic condition is maintained throughout the life-cycle of the orchid, the fungus being found in the roots, rhizome, and even in the flowers and seeds, and it is transmitted hereditarily.

The Origin of Tubers in Various Plants.—The occurrence of endotrophic Mycorhiza in the roots of species of Solanum has been recorded by various observers. Experimenting with the potato, Molliard (1907, 1920) found that tubers were not formed in aseptic cultures. Magrou (1921) placed potato seeds in a poor soil and close to *S. dulca-mara*, which always contains fungi, and found that only when the fungus invaded the potato plant were tubers formed.

Magrou also investigated tuberisation in *Orobus tuberosus* (Leguminosæ) and in *Mercurialis perennis* (Euphorbiaceæ), and from his collective studies concludes that—

(1) When the potato plant and Orobus are raised from seed, the establishment of symbiosis leads to tuberisation of the sprouts at the base of the stem; tubers are not formed in the absence of symbionts. (2) Owing to developmental differences between the two plants, symbiosis in the potato plant is intermittent, whilst in Orobus it is continuous. (3) It follows that these plants may develop in two ways: (*a*) when they harbour symbionts they produce perennial organs; (*b*) without symbionts they are devoid of perennial organs. (4) It is the rule for wild perennials to harbour symbionts, as Bernard has stated, whilst annuals are devoid of symbionts; three species of annuals (*Solanum nigrum, Orobus cœcineus*, and *Mercurialis annua*) may be penetrated by endophytes, but they quickly digest the intruders. (5) These observations confirm and supplement the view held by Bernard that tuberisation is due to the association of fungi with plants.

Mycorhiza in Ericaceæ, Club-mosses and Ferns.—Rayner (1915–16) finds that Mycorhiza are constantly present in heathers. He isolated Mycorhiza (of the genus Phoma) from *Calluna vulgaris*, in which the fungus is widely distributed, being found in the roots, branches, and even in the carpels, so that it occurs within the ripe fruit and seed tegument. Calluna seeds, when grown aseptically, give rise to poor little plants devoid of roots, but, under like conditions, in contact with Phoma the plants develop normally and form many roots.

In Lycopodiaceæ (Club-mosses) and Ophioglossaceæ (Ferns), according to Bernard, the perennial prothallus is infested, and the spores whence the plants emanate will not germinate except (as with orchid seeds) with the help of fungi.

The foregoing emphasises the significance of symbiosis in the vegetable kingdom. I will close by mentioning the theoretical deduction of Bernard that vascular plants owe their origin in the past to the adaptation of certain mosses to symbiotic life with fungi.

II. SYMBIOSIS IN ANIMALS.

(1) *Algæ as Symbionts.*

Animals of widely separated groups characterised by their green colour have long been known. Already in 1849, von Siebold attributed the colour of *Hydra viridis* to chlorophyll, which, for a period, was regarded as an animal product. In 1876, Gésa Entz concluded that the chlorophyll is contained in vegetable cells living as parasites or commensals within the animals; these cells were aptly named *zoochlorella* by Brandt (1881), whilst cells distinguished by their yellow colour were subsequently called *zooxanthella*, the latter having been first described by Cienkovsky (1871) as present in Radiolaria. Zoochlorella occur mainly in fresh-water animals; zooxanthella mainly in marine animals; the symbionts, measuring 3-10 microns in size, being found in many Protozoa, Sponges, Cœlenterates, Ctenophores, Turbellaria, Rotifers, Bryozoa, Annelids, and Molluscs.

Physiological studies upon the relations between animals and symbiotic algæ have yielded interesting results in Protozoa, Cœlenterates, and Turbellaria.

Symbiotic algæ are not usually transmitted hereditarily, each host-generation being usually infected afresh by algæ. Where Protozoa multiply by division the algæ pass directly to succeeding generations. Hereditary transmission occurs in hosts that undergo sexual multiplication (as in *Hydra viridis*). From the circumstance that in most cases symbiotic algæ are not transmitted hereditarily, we may explain the occasional occurrence of alga-free individuals in a species usually harbouring the symbionts.

Studies conducted on Turbellaria are of special interest. The best-known example of symbiosis in Turbellaria is found in *Convoluta roscoffensis*, a species that has been well studied by Keeble and Gamble (1903–7). Its larvæ are colourless, and infection occurs after hatching. The cocoon, on the day following its deposition, is already invaded by algæ.

In *Vortex viridis* symbiosis is not necessary; in Convoluta it is necessary for both partners. Mature Convoluta are never found devoid of algæ in Nature. The young larva can only feed itself for a week; as it grows older it becomes infected progressively with algæ. There are four periods in the life of Convoluta, wherein the animal lives at the expense (1) of formed substances, (2) of these and alga-products, (3) of alga-products only, and finally (4) of the algæ themselves. This constitutes a true evolution in a species from a free existence, depending only on outside sources of food supply, to a symbiotic mode of life, and lastly one merging into parasitism.

(2) *Symbiosis in Insects.*

Among insects we find a whole series of progressive adaptations toward an association with micro-organisms of different categories:

Group I.—*The utilisation by insects of micro-organisms cultivated by them outside their bodies.* To quote three examples: (1) The larvæ of the beetle *Xyloteres lineatus* (Bostrichidæ) form galleries in the wood of pines in which the fungus Ambrosia is cultivated by the larva for food. The beetle is incapable of digesting cellulose. (2) *Termes perrieri* of Madagascar builds chambers and galleries. The termites collect dead wood, chew it up finely, swallow it, the wood passing unaffected through their intestine and out in the form of small spherical masses (0·5 mm.) which are cemented together as porous cakes. Fungi which

develop upon the cakes serve as food for the termites. (3) Ants belonging to the genus Atta cultivate fungi; the queen, when about to found a new colony, carrying away a small ball of fungus wherewith to start a fresh culture in the new habitat.

Group II.—*Symbiotic organisms developing in the lumen of the intestine and its adnexa.* As examples may be cited the bacteria occurring in the intestines of fly larvæ (Musca, Calliphora, etc.), which aid the larva to digest meat; the bacteria associated with the olive-fly (*Dacus olea*); the Trychonymphids of xylophagous Termites (*Leucotermes lucifugus*).

Group III.—*Intestinal symbionts situated in the epithelial cells of the digestive apparatus.* In *Anobium paniceum*, a small beetle commonly occurring in flour, a part of its mid-gut contains cells filled with symbiotic yeasts undergoing multiplication. The symbionts are acquired by the larva on hatching, being eliminated by the female beetle.

Group IV.—*Intracellular symbionts of deep tissues.* This group of symbionts is most frequently found in insects, but their nature was not disclosed until recent years. Thus an organ, constantly present close to the ovary in Aphis, the "pseudovitellus," is now known to contain symbionts, for in 1910 Pierantoni and Šulç independently demonstrated that certain intracellular inclusions were yeasts the evolution of which they followed. Their results have been confirmed by various authors, especially by Buchner, to whose collective work on the subject most of our information regarding this class of symbionts is due.

Among the symbionts of deep tissues in insects are found a whole series of specialisations among the host-elements harbouring the symbionts. In Lecaniinæ yeasts are distributed throughout the body (perivisceral fluid, cells of fat-body); the fat-body cells may be regarded here as facultative Mycetocytes. In *Orthezia*, symbiotic bacteria occur in certain fat cells. In Cicadas, yeasts occur in fat cells which continue to accumulate fat, glycogen, and urates. In Blattids, symbiotic bacteria are found in special cells forming well-differentiated Mycetocytes. These also occur about the digestive tract of Pediculidæ (Hæmatopinus) and certain ants (Camponotus). Mycetocytes may agglomerate to form true organs termed Mycetomas, the component mycetocytes containing either yeasts or bacteria as symbionts, as in Aphids, Chermids, and Aleurodids. In Pediculus and Phthirus, parasitic on man, the mycetoma is disc-shaped and lies centrally as a distinct milk-white structure upon and indenting the mid-gut.

The mode of transmission of intracellular symbionts of insects from generation to generation may take place in different ways as defined by Buchner (1921, somewhat modified): I. The larva of each generation infects itself through the mouth (Anobiidæ). II. Infection takes place hereditarily through the egg. III. Embryonal infection as in parthenogenetic Aphids.

As already indicated, the symbionts may be yeasts, saccharomycetes, bacteria, or even nitrobacteria. Their entrance into the cells and their presence therein even in large numbers does not in many cases prevent multiplication of the invaded cells or affect their mitosis.

We know little regarding the part played by symbionts in insects; our information relates almost exclusively to their morphology, mode of multiplication, and entry into the host during its development. There are no indications that the symbionts are injurious or pathogenic. We may well ask ourselves what are the reciprocal advantages of this association, but this is a question that it is impossible to answer in view of our ignorance of physiological and biochemical processes in insects.

(3) *Micro-organisms in Relation to Luminescence in Animals.*

A fairly large number of organisms are known which have the faculty of emitting light. They are found among bacteria, fungi, protozoa, cœlenterates, echinoderms, worms, molluscs, crustacea, insecta, tunicata, and fish. As a rule, luminescence in animals depends upon the action of luciferase on luciferin, but recently a number of cases have become known wherein light production has been traced to micro-organisms, and it is with these cases that we shall deal.

Luminescent pathogenic bacteria may invade the host, as described by Giard and Billet (1889–90) for the small marine amphipod, Talitrus.

Luminescent symbiotic bacteria are present in luminescent organs of certain insects, cephalopods, tunicates, and fishes:—

Insects: Pierantoni (1914) found them in glow-worms (Lampyrus), the luminescent cells being crowded with minute bodies having bacteria-like staining reactions, these bodies being also present in the beetle's egg, which is luminous.

Cephalopods: We owe to Pierantoni (1917–20) and Buchner the discovery that luminescence in certain Cephalopods is due to light-producing bacterial symbionts living in special organs of the host. In Loligo the luminous organs, known as "accessory nidamentary glands," consist of epithelial tubes surrounded by connective tissue. In cuttle-fish (Sepiola and Rondeletia) the organs are more complicated, the glands being backed by a reflector, and provided outwardly with a lens serving for the projection of the light rays generated by the symbionts within the tubes. The symbionts are transmitted hereditarily when the Cephalopods lay their eggs. The symbionts of Loligo and Sepiola have been cultivated.

Tunicata: In Pyrosomidæ each individual in the colony possesses two luminescent organs, in which Buchner (1914) demonstrated symbiotic fungi that are transmitted hereditarily.

Fish: Of great interest are the researches of Harvey (1922) upon light production by two species of fish (Photoblepharon and Anomalops). Their luminescent organs are composed of a great number of sets of parallel gland tubes. Luminous material fills the lumen of the tubes and consists of an emulsion containing many granules and rods; the latter move about with a corkscrew-like motion, and are undoubtedly bacteria. The luminosity of the organ is due to these symbiotic bacteria.

In concluding this section dealing with light production by animals it may be repeated that we have to distinguish between (*a*) luminescence due to symbiotic organisms, such luminescence being continuous in the presence of oxygen as in cultures of luminous bacteria

(of which some thirty species are known), and (*b*) that due to animal cell-products known as luciferin and luciferase which are secreted and expelled *at intervals*, in response to a stimulus, from two kinds of gland cells, the secretions, when mixed, producing light.

Portier's Hypothesis.

The numerous cases in which symbiosis occurs in Nature have naturally led some biologists to ask if symbiosis is not a phenomenon of general significance, and perhaps essential, in living organisms. In this connexion reference must be made to the hypothesis advanced by Portier (1918), because it formulates extreme views. On faulty premises he built up an hypothesis that may be likened to a house of cards. He divides living organisms into two groups, autotrophic (bacteria only) and heterotrophic (all plants and animals), according as they are provided or not with symbionts. According to Portier, the mitochondria that are present in all plant and animal cells are symbionts. Space precludes further consideration of the subject here.

Conclusion.

The term "symbiosis" denotes a condition of conjoint life existing between different organisms that in a varying degree are benefited by the partnership. The term "symbiont," strictly speaking, applies equally to the partners; it has, however, come to be used also in a restricted sense as meaning the microscopic member or members of the partnership in contradistinction to the physically larger partners, which are conveniently termed the "hosts" in conformity with parasitological usage.

The condition of life defined as symbiosis may be regarded as balancing between two extremes—complete immunity and deadly infective disease. A condition of perfect symbiosis or balance is realised with comparative rarity because of the many difficulties of its establishment in organisms that are either capable of living independently or are incapable of resisting the invasion of organisms imperfectly adapted to communal life. In these respects the conclusions of Bernard and Magrou in relation to plants apply equally to animals. It is difficult to imagine that symbiosis originated otherwise than through a preliminary stage of parasitism on the part of one or other of the associated organisms, the conflict between them in the course of time ending in mutual adaptation. It is, indeed, probable that some supposed symbionts may prove to be parasites on further investigation.

In perfect symbiosis the associated organisms are completely adapted to a life in common. In parasitism the degree of adaptation varies greatly; it may approach symbiotic conditions on one hand, or range to vanishing point on the other by leading to the death of the organism that is invaded by a highly pathogenic animal or vegetable disease agent. There is no definite boundary between symbiosis and parasitism. The factors governing immunity from symbionts or parasites are essentially the same.

No final conclusions can as yet be reached regarding the function of symbionts in many invertebrate animals, owing to our ignorance of the physiological processes in the associated organisms. The investigation of these problems is one fraught with difficulties, which we must hope will be surmounted.

New knowledge is continually being acquired, and a glance into new and even recent publications shows that symbionts have been repeatedly seen and interpreted as mitochondria or chromidia. Thus in Aphis the long-known pseudovitellus has been shown to contain symbiotic yeasts by Pierantoni and Šulç, independently and almost simultaneously (1910); Buchner (1914) has demonstrated symbiotic luminiscent fungi in the previously well-studied pyrosomes, besides identifying (1921) as bacterial symbionts the mitochondria found by Strindberg (1913) in his work on the embryology of ants. The increasing number of infective diseases of animals and plants, moreover, which have been traced, especially in recent years, to apparently ultramicroscopic organisms, cannot but suggest that there may exist ultramicroscopic symbionts.

From the foregoing summary of what is known to-day of symbiosis we see that it is by no means so rare a phenomenon as was formerly supposed. Symbiosis occurs frequently among animals and plants, the symbionts (algæ, fungi, bacteria) becoming in some cases permanent intracellular inhabitants of their hosts, and at times being transmitted from host to host hereditarily. Among parasites, non-pathogenic and pathogenic, we know of cases wherein hereditary transmission occurs from host to host.

It is evident that we are on the threshold of further discoveries, and that a wide field of fruitful research is open to those who enter upon it. In closing, it seems but fitting to express the hope that British workers may take a more active part in the elucidation of the interesting biological problems that lie before us in the study of symbiosis and the allied subject of parasitism.

Crete as a Stepping-Stone of Early Culture: some New Lights.[1]

By Sir Arthur Evans, F.R.S.

The unique geographical position of Crete, lying almost midway between Europe, Asia, and Africa, marked it as the point where the primitive culture of Europe was first affected by that of the older civilisations of Egypt and the East. But geographically it belonged in late geological times to Anatolia, being separated from Europe by the irruption of an arm of the Miocene Sea which later became the Ægean. Thus the fauna of Crete show nearer connexions with Asia Minor, as, for example, the Cretan wild goat; and this affinity is still reflected in its Neolithic culture, of which at Knossos in places we have a mean thickness of some 6½ metres (23½ feet) as compared with about 5½ metres (19 feet) for the whole of the superincumbent strata.

The builders of the Great Palace had themselves

[1] Abridged from a lecture delivered before Section H (Anthropology) of the British Association at Liverpool on September 18.

removed the earlier Minoan or Post-Neolithic strata from the top of the original " Tell " to form the Central Court, and immediately below its pavement level some traces of rubble masonry appeared, my investigation of which, in the summer of this year, resulted in the discovery of a complete house belonging —as its contents showed — to the latest Neolithic phase.

This has supplied a most valuable record of the final stage in the development of the original culture of the island, still preserving the impress of its fundamental relationship with the mainland to the East. A female clay idol of " squatting " type is in this respect very significant. Still more important is a feature in the house plan itself, not traceable in any dwelling of the pure Minoan Age that has hitherto come to light—the appearance, namely, of the fixed hearth. The same arrangement conforms to the traditional Anatolian usage as illustrated, for example, by Troy and Sindjirli. This arrangement, as we know, was also shared by the primitive house-plans of mainland Greece from Thessaly to the Morea, but in Minoan Crete it was superseded by the use of movable hearths. On the other hand, the " but and ben " type of this Neolithic house with its side magazines itself survived in a religious connexion, as may be seen from the similar plan presented by the little shrine or " Casa Santa " of the Minoan goddess set up on the neighbouring peak of Mt. Juktas.

Whence then did the usage of the movable hearths reach Crete, which also entailed important modifications in structure? There are reasons for bringing this phenomenon into relation with a wave of southern influence which set in about the beginning of the earliest metal age in Crete, and to which was ultimately due the differentiation of the insular culture from that of the neighbouring Ægean region, and the rise of the brilliant Minoan civilisation, which in turn impressed itself on mainland Greece. A variety of evidence can be adduced indicating a very early intercourse between the Nile mouths and Crete, going back even to the age before Menes, when we know that navigation was already well advanced among the Delta population.

Remains of a series of typical predynastic vases of porphyry and other materials have come to light on the site of Knossos, while imitative stone vessels in variegated materials of indigenous fabric date back to similar models. A class of Early Minoan idols, either pointed or square below, claims a similar lineage, and —as Prof. Newberry has shown—the Minoan 8-shaped shield is itself the outcome of that which formed part of the emblem of the Egypto-Libyan Delta goddess Neith. A Minoan goddess holding this shield seen at Mycenæ seems to have been the prehistoric forerunner of Athena, and something of the cult of the Delta goddess also survives in that of the Snake goddess of Knossos.

Later influences of the same Egypto-Libyan class are traceable in certain Cretan bead-seals and amulets of the period succeeding the VIIth Dynasty. So intensive was the predynastic connexion with Crete that it seems possible that, at the time of Menes' conquest, part of the older population had found a refuge in the island.

As no objects due to this intercourse have yet appeared in the Neolithic Strata of Crete, we incidentally obtain a *terminus ad quem* for the close of the Neolithic period in the island. The date of the late predynastic epoch in Egypt cannot on any showing be brought down later than about 4000 B.C.

From the earliest dynastic period in Egypt proofs of direct intercourse with Crete continually multiply; and fresh examples of this, in the shape of fragments of diorite bowls, including a remarkable specimen with ears inside the rim, from the site of Knossos, are now available. Most of these vessels seem to date from the IVth and Vth Dynasties, from which we have the first monumental records of Egyptian sea-going fleets.

One remarkable outstanding phenomenon is that though copies of Egyptian prehistoric and early dynastic stone vessels occur elsewhere in Crete—notably of VIth Dynasty ointment-pots—the originals so far have been found only on the site of Knossos. Knossos from about the close of the Neolithic Age in Crete was thus becoming a staple of commerce with the Nile Valley.

The question thus arises, By what route did these predynastic and protodynastic objects reach this site? In view of the prevailing northerly winds it does not seem probable that early navigators from or to Egypt coasted round the iron-bound promontories of northern and eastern Crete.

Further discoveries made during the course of this year by me at Knossos and in the central region of the island throw a new light on this question. On the southern slope of the site two parallel lines of massive foundations were unearthed—evidently forming part of a monumental approach to the Palace by a broad step-way, starting from a platform on which had abutted a main southern highway. The remains of the paved way itself were brought out on the opposite side of the ravine, which had been crossed by means of a bridge; and explorations in the interior have now made clear the existence of a Minoan road-line crossing the central region of the island. Remains of this, with massive terrace walls below and above, have been followed along the western steep of Mt. Juktas in the direction of the important Minoan station of Visala, and further south are traceable at intervals ascending and crossing the watershed—here about 1800 feet in elevation—and thence heading towards Phæstos and the southern ports.

It is, therefore, probable that the Egyptian trade was conducted by means of the direct sea-passage to these ports and thence by this very ancient transit route to Knossos. While endeavouring, however, to fix the exact site of the Minoan havens, a disconcerting phenomenon presented itself, which is of some geological interest. At Matala, the Roman harbour of Gortyna, the floors of rock-cut tombs of late Greek date lie nearly two metres beneath sea-level, implying a total subsidence of some four metres at least since the beginning of the Christian era. Similar evidence comes out at the Minoan port of Nirou Khani on the north coast, where there is actually a submarine quarry. The subsidence, therefore, probably extends to the whole of central Crete, and is in strong contrast to the fact that at Phalasarna, in the extreme west

of the island, the Roman harbour has been raised from 5 to 5·50 metres above sea-level.

The direct maritime intercourse between Egypt and Crete had also its reaction betimes on Egyptian art. The spiraliform and curvilinear system that Crete itself seems to have received from the North Ægean, which affects Cretan ornament by the third Early Minoan Period—*c.* 2400–2100 B.C.—is taken on in Egypt at a somewhat later date, about the beginning of the XIIth Dynasty. But the system thus implanted in Egypt had in its turn an almost immediate reaction in Crete, and the spiraliform and other curvilinear patterns of the Middle Minoan Age often betray, by their combinations with sacred symbols and the lotus or papyrus, direct indebtedness to the scarab and ceiling patterns of Middle Kingdom Egypt. From Crete in turn these Egypto-Minoan forms passed at Mycenæ and elsewhere to continental Greece. The most characteristic patterns on the grave stelæ of the Mycenæ—often cited as an evidence of northern influence—in fact, belong to this Egypto-Minoan class.

In spite of the very ancient underlying community of Crete and Anatolia, it is clear that the earlier wave of civilising influence came not from the East but from the Nile Valley. Already in Early Minoan times this influence manifests itself in a great variety of ways, and nothing gives a better idea of the intimacy then subsisting than the spread in the island at this early epoch of the Egyptian game of draughts. By the beginning of the Age of Palaces, about 2000 B.C., however, we begin to have definite evidence of direct importation of objects and concomitant influences from the Syrian and Babylonian side. Two cylinders—one from near Knossos—date from the Age of Hammurabi. Hittite forms of signets also occur, and clay tablets of oriental type.

Two very interesting objects in the Roselle collection at New York now make it possible to trace a characteristic class of Minoan libation vessels to a remote Sumerian source, ascribed by Dr. Hall to the time of Ur-Ninā, *c.* 3000 B.C. These are a small bull and a bull's head of diorite hollowed out for the pouring of liquids, much as the Cretan vessels of the same kind that first appear about the beginning of the Middle Minoan Age, a thousand years later. Even the inlaid decoration of these shows a correspondence with that of Cretan steatite examples. "Rhytons" of this class occur also among Hittite remains, and a kindred lion-headed type was known in Syria. It can scarcely be doubted that intermediate links may ultimately be established.

The function of Crete as a stepping-stone is curiously illustrated by the fact that perhaps the most artistic object found in the Mycenæ Shaft Graves was a silver bull's-head rhyton of Minoan fabric, while part of an alabaster example of the lion's-head type, a replica of one from the Temple Treasury of the Palace of Knossos, occurred at Delphi, confirming the tradition that connects its earliest cult with this Cretan site.

Among the contents of the remarkable tomb recently discovered on the site of Byblos, containing obsidian ointment pots with the cartouche of Amenemhat III., were not only a part of a silver bowl with spiraliform repoussé work of a Minoan kind, but also a spouted teapot-like vase of the same material, which has also been attributed to a "Mycenæan" source. The nearest parallel to this is a hitherto unpublished blue faïence vase from the treasury of the Central Sanctuary at Knossos, but the indebtedness here is probably the other way, since similar forms in clay, as is shown from the contents of Hittite tombs, were at home in North Syria.

Together with these oriental connexions the reciprocal intercourse between Egypt and Crete continued to operate on either side, and a curious parallel to the history of the animal rhytons is presented by another series to which an ostrich egg forms the starting point. The Egyptian prototype is actually supplied by a vessel found by Prof. Garstang in an early Middle Kingdom tomb at Abydos and now in the Brussels Museum, where a mouthpiece of translucent blue marble is fitted to an ostrich egg recipient. It is scarcely necessary to mention here the discovery of imported polychrome pottery in XIIth Dynasty deposits in the Fayûm and elsewhere, or of the diorite Egyptian monument—probably the offering of a resident Egyptian—and the alabastron lid with the Hyksos King Khyan's name found at Knossos. It is a pregnant symptom of the maritime enterprise of Crete at the close of the Middle Minoan Age that ships of more advanced type now appear on seals that have been discovered.

The early operation of Cretan influences in Malta has recently received fresh illustration from the incised designs on the pottery of Hal Tarxien and the painted scrolls of the hypogæa of Hal Saflieni. At a somewhat later date it seems possible to ascribe to Minoan or Mycenæan agency—at least in its initial stages—the diffusion of faïence beads of the segmented and other Egyptian types to the Iberic and Britannic West. So, too, the amber-trade from the north by way of the Adriatic coast to the Peloponnese and Crete, which attained its apogee about the beginning of the Late Minoan Age, may account for the survival of Minoan and Mycenæan forms among the relics found in Illyric cemeteries like that of Glasinatz in Bosnia, as well as for certain elements in the affiliated Gaulish and Late Celtic culture.

Of the Minoan relations with inner Africa, either through Egypt or by way of the Libyan ports of the Tripoli region, some striking new evidence has been brought to light by the recent excavations at Knossos. In some of the newly discovered frescoes, apes of the Cercopithecus genus, not found nearer than the Sudan, are so vividly depicted that it is clear that the artist had studied them from the life. Tame specimens must, therefore, have existed in the great Palace, probably introduced through Egyptian agency. Of even greater interest is a frieze in which a Minoan captain in a typical embroidered loin-cloth and wearing a black goat's-skin cap is seen leading a negro troop wearing a similar uniform. It seems more than probable that such black mercenaries reached Crete through some Minoan factory on the Libyan coast. The negro element in Crete, which reached it from Tripoli and Derna under Turkish rule, is still noticeable. The employment by the Minoans of black mercenaries in the days of their expansion on the European side suggests the most modern parallels.

Obituary.

Rev. H. J. Bidder.

THE death of Henry Jardin Bidder, fellow of St. John's College, Oxford, which took place on October 19 at his house in Oxford, deprives his College and University of a wise counsellor and the world of a rare and commanding personality.

Mr. Bidder was born in 1847, and after his school-days at Harrow, spent the whole of his long life in, or in the neighbourhood of, Oxford. He was elected to a fellowship at St. John's in 1873, and having taken Orders, found ample scope for his abounding energy in the service of the Church and in acting as lecturer and tutor and subsequently as Bursar of his College. The post of Bursar he held for twenty-one years, and during that period Mr. Bidder administered the financial affairs of his College with such judgment and ability that when he resigned the office St. John's had become one of the most flourishing colleges in the University.

A man of wide sympathies, Mr. Bidder espoused with enthusiasm the cause of agriculture and forestry in the University. He took a leading part in effecting the re-endowment of the Sibthorpian professorship of rural economy and in the establishment of a professorship of forestry. Nor will it be ungracious to state that the weight of his influence counted heavily in determining his college to give generous assistance to these departments of the University, in assisting in the provision of buildings, and in putting Bayley Wood at the disposal of the School of Forestry as a training ground for foresters. Mr. Bidder served for many years on the University Forestry Delegacy and was also a most valued Curator of the Oxford Botanic Garden.

Of the many services which Mr. Bidder rendered to the world none is more conspicuous nor more widely appreciated than that of making the garden of St. John's College the most beautiful in the University and among the most beautiful in the world. To the lot of few men has it fallen to give pleasure to so many as did he by his labours in making "his" garden more perfect year by year. Those who shared his love of gardening were sure of a warm welcome to St. John's and a warm place in his heart, and there are many who count among the happiest hours of their life those spent with Mr. Bidder in St. John's garden. They were never sent empty away, but received the gifts of his large-hearted friendship and of any, even of his most precious, plants which they desired. The rock garden, designed with consummate skill and tended with meticulous care, was perhaps the achievement of which Mr. Bidder was most proud: and justly, for in it Alpine plants, even the most difficult, found congenial place, and flourished so that they made St. John's rock garden in springtime the most lovely corner of Oxford.

Tall and stalwart, authoritative, broad-minded, not always very patient, but of exquisite courtesy, Mr. Bidder was greatly beloved. He was humorous, too, with a spice of teasing malice which gave piquancy to his conversation and endeared him the more to his friends. His voice was beautiful, and there was a graciousness in his demeanour which made each time of meeting him a memorable occasion. F. K.

Dr. William Crooke.

It is with great regret that we record the death of Dr. William Crooke, the widely-known authority on Indian ethnology, which occurred on October 25 after an operation.

William Crooke was born in 1848, and after taking his degree at Dublin University, entered the Indian Civil Service (Bengal) in 1871. While engaged in official duties as magistrate and collector in the United Provinces of Agra and Oudh, he took up the study of ethnology. As a result, in 1896 he published "Popular Religion and Folklore of Northern India," and "The Tribes and Castes of the North-Western Provinces and Oudh." The latter was undoubtedly his greatest work. It naturally owed much to his predecessors, such as Risley Dalton, Tod, and Malcolm; but it differed from any previous account in supplying a more detailed description of the manners, religions, marriage customs, and institutions of the people. Its most valuable part was the record of Crooke's own observations, made in the course of a long service at Mirzapore, on the Dravidian peoples, whose culture was then rapidly disappearing before Brahmanical propaganda.

On his retirement from the Civil Service, Crooke was for a time honorary secretary of the Royal Anthropological Institute; but he finally settled at Cheltenham and devoted himself to the study of folklore and Indian ethnology. These studies bore fruit in a number of contributions to the proceedings of learned societies and in other publications. In addition to the two books mentioned above he published: "An Indian Glossary," 1903; "Things Indian," 1906; and "The Peoples of Northern India," 1907. He also contributed a large number of articles to Hastings' "Encyclopædia of Religion and Ethics." For many years he was a constant contributor of paragraphs on anthropological subjects to NATURE, and his last contributions were received only a few days before he entered the nursing home where he died.

Crooke's intimate acquaintance with folklore and primitive custom, as well as his wide knowledge of Indian archæology and history, and his explorations in the byways of the literature on India, rendered him an ideal editor. In this capacity he produced Fryer's "New Account of East India and Persia" (Hakluyt Society, 1909); Tod's "Annals and Antiquities of Rajasthan," 1920; and Herklot's "Islam in India," 1921. In each case his work was highly praised by the most competent critics.

In 1910, Crooke was president of the Anthropological Section of the British Association at the Sheffield meeting, and in 1911–12 he was president of the Folklore Society. In 1919 the University of Oxford conferred upon him the honorary degree of D.Sc., and in 1920 his own University of Dublin honoured him with the degree of Litt.D. He had recently been elected a fellow of the British Academy.

We regret to announce the following deaths:

Mr. Charles Burckhalter, astronomer and meteorologist, director of the Chabot Observatory since 1885, on September 20, aged seventy-four.

Prof. H. B. Rathke, formerly honorary professor of chemistry at Marburg University, aged eighty-four.

Current Topics and Events.

THE announcement of the award of the Nobel prize for medicine for 1922 to Prof. A. V. Hill and Prof. Otto Meyerhof, and for 1923 to Dr. Banting and Prof. Macleod, is gratifying to British research in medical science. The Toronto workers who discovered insulin share with workers at home a common inheritance of scientific tradition; their work has attracted much notice and is well known. The division of last year's prize between Prof. Hill and the professor of physiology at Kiel emphasises the friendly co-operation which has marked their work on muscular contraction since the investigations of Fletcher and Hopkins in 1908. Sir Walter Fletcher, now secretary of the Medical Research Council, was Prof. Hill's tutor at Cambridge and urged him to take up physiology. Work on muscle at that time awaited the elaboration of a new technique of investigation. It was Langley who suggested the line of approach which has since proved so productive in the hands of A. V. Hill, whose modification of the thermopile made possible the investigation of the total heat produced in a muscular contraction, of the time-relations of the heat-production, either "initial" or "recovery," and of the thermal changes associated with the passive lengthening or shortening of the muscle. Oxygen is not used in the primary break-down processes of rest or activity, but only in what, strictly speaking, may be called the recovery processes. Prof. Hill has shown that but for the body's ability to meet its oxygen liabilities in arrears, it would not be possible to make more than the most moderate muscular effort. The muscle "goes into debt" for oxygen on the security of the lactic acid liberated in activity. Mechanical response is probably due to the production of lactic acid during contraction, its sudden appearance changing the electrical and colloidal state of protein interfaces in the muscle. Prof. Hill and his collaborators then passed to the consideration of the efficiency and speed of the recovery process, to the use of the "oxygen debt" as an indicator of the absolute amount of lactic acid present in the body at the end of exercise and to other problems of muscular exertion in man. Meyerhof continued in the use of the calorimetrical and chemical methods, his account of the rôle of lactic acid in contraction running parallel to A. V. Hill's. Muscle problems apart, Meyerhof, following Hopkins, has done notable work on the mechanism of oxidation; while A. V. Hill's work on blood-gases and on nervous excitation is also very widely known.

IF committees and talk could satisfy the bibliographic needs of the present-day researcher, he would be happy indeed. Even a body no less august than the International Commission on Intellectual Co-operation, instituted by the assembly of the League of Nations, and presided over by Prof. Bergson, has been discussing the question. Meanwhile, the Committee on Bibliography and Publication appointed by the Union of American Biological Societies has presented its first report (*Science*, September 28, 1923). It proposes to publish one comprehensive series of *Biological Abstracts*, which, at the rate of 6·8 titles to the page, would produce 6000 pages a year. This would be issued in 12 monthly numbers, with a thirteenth, also of 500 pages, for the classified index. The estimated cost of manufacture and distribution is 52,144 dollars, which is to be met by 1000 institutional subscriptions of 15 dollars and 6000 individual subscriptions of 6.20 dollars. These estimates do not include cost of binding (at least 4 dollars per copy per annum), nor do they seem to allow for editorial, bibliographic, and clerical work. Valuable though this volume might be, it would still leave the needs of the systematist to be met by such a work as the "Zoological Record," nor could its classified index, based on brief abstracts, really be what the committee calls "the modern, detailed, searching subject index." The prospect, therefore, is somewhat appalling, and suggests anew that modern scientific authorship will perish under the weight of its own products. But are these 6500 pages, for biology alone, really necessary? Would not an analytic index, competently and honestly compiled, be both less expensive and of greater ultimate value?

MAJOR H. H. KING, writing from the Central Research Institute, Kasauli, Punjab, directs attention to the statement made by Prof. I. P. Pawlow, in his lecture before the International Physiological Congress held in Edinburgh last July, to the effect that he has experimentally demonstrated the inheritance of an acquired nervous character (*British Medical Journal*, August 11, p. 256). The statement, as Major King suggests, is so far-reaching in its significance, that the results of the further experiments now in progress will be eagerly awaited. Up to the time of his leaving Russia, Pawlow's experiments had not demonstrated the direct inheritance of an acquired or "conditioned" reflex in the form of an inborn or "unconditioned" reflex; what he claimed to have shown was that the acquisition, under identical treatment, of a "conditioned" reflex became increasingly rapid in successive generations of mice. It is clear, however, that his results had led him to regard it as probable that eventually, after a sufficient number of generations had been exposed to the training, the period of training needed would fall to zero, and the reflex, acquired in the earlier generations by oft-repeated association, would eventually appear as an inborn, unconditioned character. It would be worse than useless at this stage to discuss the possible meaning or mechanism of such a process. We must await the confirmation and full exposition of the facts. But it must, in any case, be regarded as an event of the highest significance that an observer of such pre-eminence, and so intensely objective in his methods, should have been led even to such preliminary conclusions.

A VALUABLE addition to the collection of old maps in the British Museum has been made by the purchase of a hitherto unknown Italian world map dated 1506. A reproduction of the map is given in the *Geographical*

Journal for October, and in an accompanying article Mr. E. Heawood explains that the author was Contarini, who appears to be quite unknown as a cosmographer, and that Roselli was the engraver and perhaps the publisher. The map may have been produced at Venice, but there is also some evidence that it appeared at Florence. In some respects it is reminiscent of the map of Johan Ruysch of 1508, but in detail there is little close agreement. The resemblance is greater with Waldseemüller's map of 1507, but Mr. Heawood believes that this is due to a use of common sources. In Europe the general outlines, except in the north, are good. The outline of Africa is striking and much better than Waldseemüller, but the interior topography is almost entirely Ptolemaic. There is an extraordinary misplacement of the Blue Nile, derived, Mr. Heawood believes, from some early maps then existing in Italy. The chief interest in the map, however, lies in its being the first to show the result of Columbus' voyages. The priority that passed from Ruysch to Waldseemüller must now be yielded to Contarini. The author was evidently alive to the possibility of South America being a large continent, but there is no indication on his map of any land barrier closing the western seaway to Cathay. The article includes a facsimile of the map.

MR. ALAN G. OGILVIE, who has succeeded Mr. G. G. Chisholm as lecturer in geography in the University of Edinburgh, gave his inaugural address, "Modern Geography as a Study and as an Aid," on October 12. He pointed out that the great volume and complexity of the data comprised by the various natural and humane sciences result in an increasing need for work of correlation and synthesis such as geography performs. In this the data furnished by other workers are discussed by geographers always in relation to place. The study of regional geography is still in its infancy, for complete regional monographs based upon field work exist for only a small part of the earth's surface; and synthetic regional study is the main function for geographical research in the future. In regions largely unsurveyed the compilation of provisional maps can be best carried out by persons well trained in physical geography, and such maps are urgently required by men of science working in relatively unknown areas. Much fruitful investigation will result from the collaboration of geographers with workers in other fields such as geology and biology, archæology and history, economic and social science. Geography along with other sciences can help towards a reasonable and gradual redistribution of the world's population, thus relieving the stress due to overcrowding, by directing the streams of suitable emigrants to lands in which they can flourish.

THE position of the Chemical Hall in the British Empire Exhibition at Wembley next year is in many ways a good one. Visitors to the Exhibition arriving at Wembley Park Station will enter at the north entrance, and the Palace of Industry is on the right-hand side of the main avenue which runs straight to the Stadium—north to south. The Chemical Hall is in the north-east corner of the Palace of Industry: it is surrounded by two of the 75-foot gangways, and there are three main entrances to it. The exhibits will be grouped roughly in five divisions: (*a*) Heavy chemicals; (*b*) dyestuffs and intermediates; (*c*) fine chemicals; (*d*) soap and perfumery; and (*e*) scientific. A scientific committee consisting of the following representatives of scientific societies has been appointed: Mr. J. Baker, Mr. F. H. Carr, Mr. E. V. Evans, and Dr. Herbert Levinstein (Society of Chemical Industry); Dr. J. T. Hewitt and Prof. J. F. Thorpe (Chemical Society); Mr. J. B. Atkinson (Society of Dyers and Colourists); Mr. T. Marns and Mr. E. T. Neathercoat (Pharmaceutical Society); Dr. Stephen Miall (Federal Council); Mr. R. Pilcher (Institute of Chemistry); Commander R. E. Stokes Rees (Institution of Petroleum Technologists); Prof. J. W. Hinchley and Mr. W. J. U. Woolcock (Institution of Chemical Engineers). Mr. Woolcock is serving on all the committees concerned with the scientific side of the Exhibition, in order to act as general liaison officer and to avoid undue overlapping.

REPORTS have recently appeared in the Press of great changes in the depths of the South Atlantic. A note in the *Geographical Journal* for October states that the Hydrographer to the Admiralty contradicts these statements. They arose apparently from the existence, which is well known, of a ridge with depths of 480 fathoms about 800 miles from the Cape on the direct route of the cable between St. Helena and the Cape. Repairs to this cable have lately brought into prominence the occurrence of this ridge in contrast with the surrounding depths of 2500 fathoms and upwards.

THE introduction of European animals into Australia has produced a noticeable diminution in the numbers of many of the native species, some of which appear to be on the verge of extinction. In these circumstances the Trustees of the British Museum thought it desirable to acquire examples of the Australian fauna, particularly mammals and birds, and they sent out a collecting expedition for that purpose. The leader is Capt. George H. Wilkins, who was a member of the Stefansson Arctic Expedition and biologist on the *Quest*. The first station chosen for collecting was in southern Queensland, about 350 miles inland; work was carried on in this area from April 25 to June 11, and the specimens obtained there have recently arrived at the Natural History Museum. The second station is in northern Queensland.

THE first number of the new monthly publication, the *Journal of Scientific Instruments*, dealing with the principles, construction, and use of scientific instruments, has appeared. It is produced by the Institute of Physics with the co-operation of the National Physical Laboratory and is a quarto of 32 pages sold at 2*s*. 6*d*. There are three articles of considerable length on temperature control for the Pulfrich refractometer and on the measurement of heights by aneroid and of internal diameters of transparent tubes. Shorter articles on a new relay,

a recording drum, a balance in which the fine adjustment is made by a chain hanging from the pan, and a recording katathermometer, followed by two pages of notes and reviews, complete the part. The character of the articles and illustrations promises well for the future of the *Journal*.

THE twenty-seventh annual meeting and autumn foray of the British Mycological Society was held at Windsor on September 28-October 3. The president, Prof. O. V. Darbishire, dealt generally with the subject of lichens in his address. Lichenologists of the last century, typified in the person of William Nylander (1822–1899), were almost entirely opposed to Schwendener (1829–1919). They felt that his theory of the dual nature of lichens was not true and that the autonomy of the group of lichens was threatened. This old contrast between systematist and physiologist is now almost gone. Systematic lichenology is now in such a state that an appeal is made to lichenologists to work through lichen groups, genera or even species monographically. The difficulty of defining a lichen-species is often very great. This is in part due to the fact that the lichen fungus, anatomically as a rule the predominant partner, in the simple system of symbiotic co-operation existing in the lichen, has thrown overboard the structural traditions of its free-living saprophytic or parasitic ancestors. The result is that the rock-forms of two allied species will in structure often be more like one another than they will be like their respective normal bark-inhabiting parent forms. The evolution of the lichen is proceeding along very definite lines, from the flat crustaceous but areolate, to foliaceous, upright foliaceous, and finally true fruticulose forms. The highest physiological differentiation is reached in such forms as Cladonia, where we get stem and dorsiventral leaf clearly separated. Other papers were contributed on "Epidemic Plant Diseases," by Mr. F. T. Brooks; "The Fungi found growing in a Blackbird's Nest," by Sir H. C. Hawley; and an account by Mr. J. Ramsbottom of "An unpublished Monograph on Discomycetes by M. C. Cooke." Mr. J. Ramsbottom was elected president for 1924, Miss G. Lister vice-president, and Messrs. W. J. Dowson and C. J. Sharpe to the council.

THE autumn meeting of the Society of German Chemists was held at Jena on September 26-29, and about six hundred members were present in spite of the present difficulties. No festivities of any kind took place, except the performance of Goethe's play, "Stella." The following were among the subjects of scientific lectures in a very full programme:—Prof. Dr. Neuberg: Review of recent research in fermentation chemistry, and demonstration of methods of determining the direction of fermentation and fixing intermediate products. Prof. Lemmermann: The position of Germany as regards supply of artificial fertilisers; the prospects of enlarging the yield to such an extent that Germany can grow her food supply at home. Experiments were described for partially replacing phosphoric acid by colloidal silicic acid. Dr. Edeleanu: Description of the process of refining certain kinds of petroleum (such as Rumanian and Californian) containing a large amount of unsaturated and benzolic hydrocarbons by liquid sulphurous acid, and of the apparatus constructed for this purpose by the Borsig Works. This process permits the manufacture of a good burning oil and the production of the other components of the petroleum in their original condition. Prof. Dr. Stock deplored the poor financial condition of experimental chemistry at the German high schools, and remonstrated against the reduction of this most important branch of chemical education. Prof. Dr. K. Hess: Review of recent researches on cellulose. The simple cellulose molecule is represented by $C_6H_{10}O_5$, as stated by Prof. Green thirty years ago. Detailed investigation of the cuprammonia solution of cellulose has proved this to be correct. Prof. Linck: A new proposal for the working-up of the magnesium chloride waste liquors in potash works. In ten sections more than eighty lectures were given on various problems of pure and applied chemistry, industrial law, education, etc.

THE annual report of the Meteorological Committee to the Air Council for the year ended March 1923 has just been issued; this is the sixty-eighth year of the Meteorological Office. Of recent years much development and extension has occurred consequent on the necessary investigation of the upper air for the requirement of aircraft and for naval and military purposes. Most public meteorological work is now absorbed under Government management, and without doubt this tends greatly to the advancement of meteorology. The system of wireless weather reports from ships in the Atlantic is said to be extremely efficient, the whole of the work on the ships is voluntary, and no "ships' charges" are made by the Marconi Company. Some return is made for this voluntary help by broadcasting two messages a day specially prepared by the Office for the shipping approaching our western coasts. About 500 ships regularly and voluntarily send returns in connexion with the work undertaken by the Marine Division, and discussions of use to seamen are actively maintained. The Forecast Division is on the alert to take advantage of every opportunity to ensure improvement in the accuracy of the forecasts. In addition to the European observations, data are received daily from 29 stations in the United States, from Iceland and Greenland, and occasionally from the steamship *Maud* of the Norwegian Polar Expedition. Forecasts are prepared three times each day for issue to the Press and special week-end forecasts are prepared on Thursday and Friday. The Climatological Division deals with all information bearing on climate. Upper air observations entail much work, and the British Rainfall Organisation is entirely under the control of the Meteorological Office.

SIR HUMPHRY ROLLESTON has been appointed a physician-in-ordinary, and Mr. E. F. Buzzard physician extraordinary, to the King.

MR. T. SHEPPARD, of the Hull Municipal Museums, and Dr. T. W. Woodhead have been elected honorary

life members of the Leeds Naturalists' Club and Scientific Association, in recognition of their work in Yorkshire.

DR. J. H. JEANS will deliver the Van der Waals memorial lecture at the meeting of the Chemical Society to be held at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1, on Thursday, November 8, at 8 P.M.

SIR OLIVER J. LODGE will deliver his presidential address to the Röntgen Society on "X-rays and the Atom," at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C.2, on Tuesday, November 6, at 8.15 P.M. Tickets of admission can be obtained from the Hon. Treasurer of the Röntgen Society, 33 Newton Street, W.C.2.

SIR ARCHIBALD GARROD, Regius professor of medicine at Oxford, is to deliver the Harveian oration of the Royal College of Physicians of London in 1924. Dr. C. Singer will deliver the FitzPatrick lectures on November 6 and 8, at 5 P.M., on "The History of Anatomy," and Mr. Edmund Gosse the Lloyd Roberts lecture on "Personal Relations between Medicine and Literature," on Tuesday, November 20, at 5 P.M.

DR. ANDREW BALFOUR has been appointed by the transitional executive committee, under the chairmanship of the Minister of Health, to be Director of the School of Hygiene which is to be established in London. The foundation of the School, which was referred to in NATURE of July 28, p. 149, was made possible by a gift of two million dollars by the trustees of the Rockefeller Foundation.

SIR J. FORTESCUE FLANNERY has accepted the invitation of the Council of the Junior Institution of Engineers to become president of the Institution in succession to Capt. H. Riall Sankey. His induction will take place at a meeting to be held at the Royal Society of Arts on Friday, December 7, when he will deliver his presidential address, "Marine Propulsion during fifty years." Tickets for the meeting may be obtained from the Secretary of the Institution, 39 Victoria Street.

A DISCUSSION on "The Reproduction of Sound by Loud Speakers," arranged by the Physical Society and the Institution of Electrical Engineers, will be held on November 29 in the hall of the Institution of Electrical Engineers. There will be two sessions, 5.30-7 P.M. and 8-9.30 P.M., and during the afternoon visits will be made to the studio of the British Broadcasting Company at Savoy Hill.

FROM the income of the R. 38 Memorial Prize Fund, a sum of twenty-five guineas will be offered as a prize for the best paper received by the Royal Aeronautical Society, on some subject of a technical nature in the science of aeronautics. Other things being equal, preference will be given to papers which relate to airships. The prize is open to international competition. Intending competitors should send their names to the Secretary of the Royal Aeronautical Society, 7 Albemarle Street, London, W.1, on or before December 31, with such information in regard to the projected scope of their papers as will enable arrangements to be made for their examination. The closing date for the receipt of papers will be March 31.

A PLANT Pathologist is required in the Botanical Division of the Department of Agriculture of the Union of South Africa. The duties of the post will primarily be connected with carrying out pathological investigations regarding the outbreak of disease in tobacco. Candidates must possess a university degree and have taken botany and the allied sciences in the final examination. Forms of application may be obtained from the Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2. The latest date for the receipt of applications for the position is November 20.

AT the statutory meeting of the Royal Society of Edinburgh held on Monday, October 22, the following officers were elected :—*President*: Prof. F. O. Bower; *Vice-Presidents*: Major-General W. B. Bannerman, Dr. W. A. Tait, Principal J. C. Irvine, The Rt. Hon. Lord Salvesen, Prof. J. H. Ashworth, and Prof. T. H. Beare; *General Secretary*: Prof. R. A. Sampson; *Secretaries to Ordinary Meetings*: Dr. A. Lauder and Prof. W. Wright Smith; *Treasurer*: Dr. J. Currie; *Curator of Library and Museum*: Dr. A. Crichton Mitchell; *Councillors*: Prof. H. Stanley Allen, Sir Robert Blyth Greig, Dr. J. Ritchie, Prof. E. Maclagan Wedderburn, Prof. T. H. Bryce, Prof. J. Y. Simpson, Prof. D'Arcy W. Thompson, Sir James Walker, Prof. E. T. Whittaker, Prof. H. Briggs, Mr. W. L. Calderwood, and Prof. T. J. Jehu.

THE annual meeting of the British Association of Chemists was held in the Chemical Department of the University of Birmingham on Saturday, October 27, under the presidency of Dr. Herbert Levinstein, who was re-elected for another year of office. During this meeting the laboratories and workshops of the University were thrown open for inspection and an exhibition of research apparatus and specimens was arranged by the teaching and research staffs of the University. The British Association of Chemists, which was founded in 1917, exists to safeguard the economic and general interests of chemists and to secure wider recognition of the national importance of the profession. The qualifications for admission to full membership are either (1) a university degree or equivalent diploma with one year's practice in applied or teaching chemistry, or (2) a sufficient general education and scientific training with seven years of professional practice. At the present time there are about 920 full members. This Association issues a quarterly Bulletin in which are published the annual report of the Council, the Proceedings of the Association, and other matters appertaining to the material and professional welfare of its members. These activities include an unemployment benefit fund, an appointments bureau, and a legal aid fund.

THE Streatfeild memorial lecture was delivered at the Finsbury Technical College on October 25 by Mr. E. M. Hawkins, who took analytical chemistry

as his subject. First among the qualifications required in the analyst is accuracy and trustworthiness, to which should be added the ability to decide to what degree of accuracy his results attain. Secondly, there is the need for rapidity to be associated with accuracy, as few students realise the speed of manipulation which is required of them when they obtain a post after leaving college. Thirdly, it is of great importance that students should cultivate the gift of expressing results suitably in a report. Much good experimental work is marred by the inability of the chemist to write up his results in such a way that the bearing of the work can be properly appreciated by those who read the report. The chemist should not be easily moved from an opinion formed after careful consideration of results obtained by patient investigation. In conclusion, the lecturer stated that of the three classes of men practising chemistry, namely, works chemists, public analysts, and consultants, the first class will greatly outnumber the public analysts when trade revives, while consulting chemists will be men of wide experience and high attainments who will be called upon by manufacturers to solve their problems and should be highly remunerated for such work.

MESSRS. WHELDON AND WESLEY, LTD., 2 Arthur Street, W.C.2, have just sent out a new catalogue (New Series, No. 9, 1923) of second-hand works on ornithology, compiled with their usual care. It contains nearly 1300 titles, and should be seen by all interested in the subject.

MR. W. H. ROBINSON, 4 Nelson Street, Newcastle-on-Tyne, has just issued catalogue No. 9, 1923, of "Rare and Standard Books" offered for sale by him. Many books of science, voyages, and travels are included, and there is a very interesting section on "Americana."

MESSRS. H. K. LEWIS AND CO., LTD., 136 Gower Street, W.C.1, have just issued a list of the new books and new editions added to their Medical and Scientific Circulating Library during August and September. As it is practically a list of the medical and scientific books published during the months in question it should be a useful guide to others than subscribers to the library.

PART III. of Sotheran's Catalogue of Science and Technology has just reached us from the publishers (140 Strand, W.C.2). It gives the titles of, and in many cases comments upon, upwards of 1500 works on the subjects of astronomy and astrology, chronology, geodesy, horology, and dialling. Many very rare books are included, among them being a unique star atlas entitled "Uranographia Britannica," published in 1750 and reported to be hitherto unknown. The catalogue should be seen by all who are interested in books dealing with the subjects named.

MESSRS. W. AND G. FOYLE, LTD., 121-125 Charing Cross Road, W.C.2, have sent us a copy of their catalogue (Dept. No. 3, September) of second-hand books, some 700 in number, which they have for disposal. The catalogue is classified under the headings: General Science, Mathematics, Astronomy and Surveying, Mathematical Tables, the New Physics, General Natural History, Anthropology and Ethnology, Evolution, Variation, Heredity, Genetics, Botany, Zoology, Microscopy, Collectors' Manuals, Geology, Palæontology, and Biography. We learn that Messrs. Foyle have recently organised a new department for the supply of books relating to science.

Our Astronomical Column.

NEW COMET.—The first cometary discovery of 1923 was made on October 14, at $13^h\ 18^m{\cdot}2$ G.M.T., by Mr. Doubiaco at Kasan. The comet was of magnitude 8·0, and its position was R.A. $7^h\ 46^m\ 42^s{\cdot}67$; south declination, $20°\ 37'\ 31''$. The daily motion was $+6^m\ 40^s$; south, $4°\ 51'$. The rapid motion indicates that the distance from the earth was small.

Unfortunately, owing to delays in Russia, the news did not reach western Europe until October 25, and by that time it may be inferred that the comet had passed below our southern horizon.

TWO LARGE FIREBALLS.—Mr. W. F. Denning writes that on the evenings of October 16 and 17 very fine meteors were seen in the south-west of England. The first appeared on October 16, at 9.28 P.M., and was well observed by many persons in the counties of Gloucestershire, Somerset, and Devon. It gave a brilliant illumination. Its height was from about 63 to 44 miles, and it passed from above Poole, Dorset, to a few miles south-west of Reading. The radiant point was indicated in Aquila at 301°–9°.

The fireball which appeared on the following night, October 17, at 11.57 P.M., was of extraordinary splendour, and created a startling effect upon many persons who were in a favourable position for witnessing its full effect. About ten observations have come to hand from Cornwall, Devon, Gloucester, and Somerset, and from these it is indicated that the fireball pursued an horizontal flight at an elevation of about 55 miles above the earth's surface. The radiant point was situated in Hercules and not far from the north-western horizon at the time of the meteor's appearance. The illumination it gave was estimated as greater than that of the full moon, and during its flight the nucleus gave a succession of three vivid outbursts of remarkable intensity.

THE SPIRAL NEBULÆ.—Mr. J. H. Reynolds replies in the October issue of the *Observatory* to the articles of Prof. Perrine and Mr. Gifford in the September number. The latter had objected that the number of the spirals approached half a million, which would give an improbably high mass, if they were composed of dust expelled from the Galaxy. Mr. Reynolds notes that many of the small nebulæ suspected to be spirals at the Lick Observatory have been shown at Mt. Wilson to be nebulous nuclei of a different character from spirals. The number of known spirals does not exceed 2000.

The great difference of illumination between the nucleus and the outer portions of the spirals is considered fatal to their being external galaxies similar to our own.

Further, the unsymmetrical distribution of the spirals in galactic longitude has to be considered in any discussion of their nature.

Research Items.

GYPSY SLAVERY.—Dr. M. Gaster, in the Journal of the Gypsy Love Society (Third Series, vol. ii., Part 2) publishes a remarkable series of facts drawn from a case decided in Moldavia in 1851, which shows that at that time the sale of Gypsies must have been comparatively common, as there seems to have been a fixed, or at any rate normal, price at which slaves were sold. The persons offered for sale fall into four groups, including various trades, some hereditary and others in which the son practises a craft different from that of the father. Sales of this kind go back at least to the beginning of fifteenth century.

THE SECRETARY HOUSE IN MARYLAND.—Mr. L. V. Lochwood contributes to the Brooklyn Museum Quarterly (July 1923) an account of this historic house. The site was granted to Henry Sewall of London, who arrived with his family in Maryland in 1661 and the house was named after him, Secretary of the Province, a large landowner, and a man of high importance. It was occupied by him and his family until his death in 1665 and the remarriage of his widow to Charles Calvert, 3rd Baron Baltimore, third Land Proprietor of Maryland. The house is of brick laid in Flemish bond, and is a typical seventeenth century Virginia or Maryland house of the wealthy class. All the furniture shown in the house at present dates before 1725. Mr. Lochwood's article fully describes this interesting building and its contents, and is illustrated by a series of good photographs.

ANTIQUARIAN WORK IN EGYPT.—In *Ancient Egypt* (Part 2, 1923) Sir W. Flinders Petrie describes an important tomb on the shore-cliff at Byblos, twenty miles north of Beyrut. A fine obsidian vase bears the name of Amenemhat III. and the tomb may be safely assigned to the period of the XIIth dynasty. The Syrian objects are of even greater importance, as the tomb furnishes a firm starting point for the dating of Syrian types, and for the relations of Egypt with Syria. This paper is followed by a report by M. Noel Giron of the French Embassy on a tomb found at Sheykh Fadl in the eastern deserts, dating from the Old Kingdom and containing Aramaic inscriptions. These point to a Jewish settlement so far up in Egypt as early as the reign of Manasseh, and the mention of Tirhaka shows that the family went back to eighty years before the fall of Jerusalem. Their natural familiarity with Greek words, objects and thoughts through the Greek camp of Tahpenes throws strong light on the criticism of the prophetic books.

THE CHINESE JUNK AND SAMPAN.—At the ninth Indian Science Congress, the proceedings of which are reported in the Journal of the Asiatic Society of Bengal, New Series, vol. xviii., 1922, No. 6, Mr. J. Hornell, comparing the Chinese junk and sampan, concludes that the sampan is ultimately derived from a modification of the double canoe in use until comparatively recently for sea work throughout Polynesia, and in a simple form still employed on inland waters in India, and that the junk is in turn a development of the sampan type. The truncate transom bow and stern of the sampan probably represent cross planking fitted between the bows and sterns of the two canoes forming one double canoe, while the two projections that curve upwards from the stern of the sampan appear to be the homologues of the up-curved sterns of the two hulls in the double-canoe form. In the some way, the median rudder of the sampan and the junk and the anchor platform that gives a square-bow appearance to the junks are what would be expected if these crafts developed from two canoe hulls joined together by a planked deck platform. The facts point to the range of the sea-going double canoe having extended in former days to India and China, the inventors and users being the ancestors of the present Polynesian race, who probably occupied the maritime districts of China at the time the Chinese left their original homeland in north-east Central Asia.

CATTLE AND EXCITEMENT FROM BLOOD.—In the *Psychological Review* (Vol. 30, No. 5) Prof. G. M. Stratton gives a very interesting account of his attempt to verify a popular belief. It is widely held that cattle react powerfully and perhaps instinctively to blood, and to get definite expression of this view from persons accustomed to observing cattle, he obtained testimony from a large number of cattlemen. They all replied to the effect that nothing else is so irritating or exciting to cattle as the smell of blood. As to the kind of emotion aroused, there was less unanimity, some ascribing it to anger, others to fear, aversion, or curiosity. The reports, however, were quite clear that blood did have a marked emotional effect. To determine the truth of these views, experiments were carefully conducted on cattle in the Berkeley Hills. Both cow's and horse's blood were used under careful experimental conditions. The experiments proved, however, more exciting to the experimenters than to the cattle. In general, the observations showed that while individual cattle displayed mild interest, there was little of that excitement spoken of by the cattlemen, no herd-seizure of alarm or rage. The author concludes, not that the cattlemen had no grounds for their belief, but that they were wrong in ascribing the excitement to blood alone; when excitement occurred it was probably due to the presence of blood in union with other factors—*e.g.* with cries of pain, or with the sight of wounded cattle. He believes that the reaction of cattle to blood, and probably of human beings too, is less of a native physiological reflex than is commonly thought, being largely influenced by special experience.

AN ARTIFICIAL PLANT CELL.—Dr. D. T. Macdougal has found an interesting method of attack upon the problem of the permeability of the plant cell and the factors that cause it to vary (Proc. Amer. Phil. Soc., vol. 62, pp. 1-25, 1923). He converts a Soxhlet extraction thimble into a semi-permeable cell by impregnating the cellulose with various substances analogous to those entering into the composition of the natural plasma membrane and plant wall, such as pectin, agar, lecithin, etc. Subsequently the rate of endosmose of such cells is noted when they are filled with sugar solution and immersed in external solution containing different salts. The rate of entry of these salts into such cells can be followed by conductivity measurements; the exosmosis of sugar can also be estimated quantitatively. Potassium ions show a high rate of penetration into such cells, with very little action on the colloid in the wall; calcium, on the other hand, penetrates least, but exerts a powerful aggregating effect upon some of the colloids. The rate of endosmose into the artificial cell increases as the permeability is lessened, and is thus usually most vigorous when immersed in the solution of a calcium salt.

OILS FROM INDIAN PLANTS.—The Indian Institute of Science, Bangalore, continues to publish in its Journal, under the editorship of Dr. M. O. Foster, the results of the examination of the natural products of

India. Among recent papers may be noted two from the Department of General and Organic Chemistry, namely: (1) a report upon cashew kernel oil by C. K. Patel, J. J. Sudborough, and H. E. Watson (vol. vi. part 6). The cashew nut is the fruit of *Anacardium occidentale*, Linn., an evergreen tree indigenous to S. and Central America, now cultivated in India. The nut contains some 42 per cent. of oil, but has not been much used as a source of oil, because of its ready sale for dessert and for use in the preparation of nut chocolate. (2) Hongay oil, extracted from the seeds of one of the commonest of Indian trees, *Pongamia glabra*, Vent., is used in Hindu medicine for the treatment of skin diseases; the oil has been fully reported upon by R. D. Desai, J. J. Sudborough, and H. E. Watson (vol. vi. part 5). From the Biochemical Department appears a paper by Gilbert J. Fowler and Talwar Dinanath (vol. vi. part 7) upon the production of sugar during the ripening of the fruit of *Bassia longifolia*. The seeds of this plant are used for oil, and the authors point out, as possibly of commercial significance, that, if the fruit is gathered and stored a few days under suitable conditions, sufficient sugar may be found in the pulp after removal of the seeds to make this waste product available as a source of alcohol upon fermentation.

Soil Acidity and Light Intensity.—In a pamphlet published by the Cambridge University Press entitled "Studies in Soil Acidity—the Importance of the Light Factor," Mr. J. L. Sager gives an account of ecological studies carried out in the Alpine Laboratory of "La Linnaea," Valois, Switzerland. Soil samples were taken near the roots of dominant plants in and around the forests of a district characterised by gneiss, granite, and schists. Hydrogen ion concentration measurements were made by the colorimetric method on extracts prepared by shaking the soil with water and filtering after standing for thirty minutes. Tables of P_H values, dominant plants and amount of shade show that several plants, usually described as calcicole, are not confined to the alkaline soils and also bring out a correlation between soil acidity and light intensity. The acidity of the soil steadily decreases on passing from the deep shade of the spruce forest, through the lesser shade of the larch forest, to the open; whilst the soils exposed to the scorching sun at still higher altitudes above the forests are only slightly acid. Cases of high acidity with high light intensity occur only where the soil is badly aerated or frequently waterlogged. The author advances the hypothesis that light is able to lessen the acidity of the soil.

Species-crosses in Cochlearia.—The condition of polyploidy, or species with one or more extra sets of chromosomes, is being found with surprising frequency in plant genera. The latest case of the kind is described by Mr. M. B. Crane and Miss A. E. Gairdner (*Journ. Genetics*, vol. 13, No. 2) in species of Cochlearia. They find that *C. officinalis* and *C. alpina* have 28 chromosomes, *C. danica* 42, and *C. anglica* 49-50, all the numbers being thus multiples of 7. They have also made crosses between the various species, with interesting results that are as yet incomplete. The range of variation of the F_2 offspring is in some cases greater than the combined ranges of the parents. The interesting condition is disclosed that the forms with higher chromosome number do not have larger nuclei, and there is some indication that the higher numbers have arisen through some process of fragmentation or transverse fission. Further investigation will lead to a more complete analysis of the changes involved. This is also the beginning of a valuable and much-needed increase in our knowledge of species-hybrids.

The Molluscan Genus Sculptaria.—In west and south-west Africa there is found a small but beautiful little genus of land shells first described by L. Pfeiffer in 1855 under the name Sculptaria. This has been recently proved anatomically by Dr. E. Degner (*Arch. Molluskenk.*, 1923, No. 4) to belong to one of the more primitive groups of helicoids, the Endodontidae. A considerable collection of these shells, which was made by Mr. P. R. Frames when serving with the Northern Force in the campaign in German South-west Africa in 1914–15, having been placed with other material in the hands of Mr. H. C. Burnup, he has been able to give a monographic account of the genus (Ann. Natal Mus. vol. v.). Three new species are described, bringing the total up to eight, and the whole are carefully differentiated and illustrated with excellent figures drawn by the author himself.

Standard Inductance Coils.—The Bureau of Standards has issued a leaflet giving detailed instructions for the construction of a series of single layer inductance coils suitable for laboratory standards. The series of "inductors," 17 in number, have been designed to cover the approximate inductance range of 8 to 5000 microhenries. Each successive coil arranged in order of magnitude and beginning with the smallest has 50 per cent. greater inductance than the preceding coil. Very little mechanical skill is required to make these coils. It is a real step in advance when you can give instructions at once to a mechanical assistant to make coils of any specified inductance. These coils in conjunction with a variable air condenser form a very accurate and trustworthy wavemeter. Full working diagrams are given, and the costs for material and labour are very small. To those who remember the difficulties of measuring or calculating small inductances twenty years ago, the ease with which standard inductances, even those which have to be used with high frequency current, can now be constructed, is wonderful.

Interferometer Experiments in Acoustics and Gravitation.—The Carnegie Institution of Washington issues as Publication No. 310 a report by Prof. Carl Barus on further experiments in which the interferometer is used for the measurement of very small quantities. These are in the main a development of the acoustic investigations with the pin-hole probe already described in Publication No. 310, 1921. Pressure variations at a node are converted into static pressures through the intervention of the pin-hole and measured at a mercury U-gauge, read by displacement interferometry. The pin-hole probe responds effectively to nodes in organ-pipes, but ignores the antinodes. With a device so sensitive to nodal regions the construction of a pin-hole resonator suggested itself. Great difficulty was encountered in the construction of the pin-hole. Both the size and the slope of the walls are critical. A salient pin-hole generates acoustic pressure, a re-entrant pin-hole acoustic dilatation, and there is neutral behaviour between the two. Within its restricted field the pin-hole resonator serves admirably for the acoustic survey of the interior of a room in which an organ pipe is sounding. If the phenomena were visible, the room would probably have the stratified appearance of a vacuum-tube stimulated by electric discharge. For a given position of the pipe, nodal regions alternate with anti-nodal regions, quite irregular in distribution but none the less fixed in position. An account is given also of work on gravitation, in which an endeavour is made to ascertain with what accuracy the constant may be found in a self-contained apparatus under ordinary laboratory conditions. The results are encouraging, but the experiments are not yet completed.

Physical Chemistry and Physiology at the British Association.

INTERFACIAL PHENOMENA.

IN the Physiology Section, at the recent meeting of the British Association at Liverpool, important communications on this subject were given by Prof. W. Ramsden and collaborators, and some remarkably pretty demonstrations were shown.

Mr. J. R. Bruce and Prof. W. Ramsden showed that egg-albumin became irreversibly coagulated at the gas-water surface, even when all such mechanical disturbances as could compress the adsorbed protein film laterally were strictly excluded. The solubility or insolubility of the adsorptum was ascertained *in situ* by subjecting the rigid adsorption surface to three different treatments :—(1) it was washed from below with large volumes of water ; (2) bile salt was introduced into the depths of the underlying solution ; (3) it was made continuous with a surrounding surface of water maintained in a clean condition and of full normal surface-tension. If the surface rigidity persisted, it was argued that the adsorbed protein had lost its initial solubility. It was concluded that with egg-albumin coagulation took place by the catalytic influence of surface-conditions, and that gross mechanical factors played no essential part,—"mechanical surface coagula" should be termed "massed surface coagula."

True coagulation was a dehydrating condensation of the amino and carboxyl groups of large numbers of neighbouring protein molecules. Metaprotein formation was a precisely similar condensation of a relatively small number of molecules. The size of the complexes formed depended mainly on the concentration of the protein at the time when the reacting groups were activated. Protein adsorbed at a gas/water interface was highly concentrated and the denaturation which followed resulted therefore in the production of coagulated protein. It was also shown (by method 3) that egg-albumin, fibrinogen and edestin became irreversibly coagulated within less than five seconds of attaining a gas-water surface.

Mr. J. Brooks and Prof. W. Ramsden showed that interfaces between water and benzene or water and paraffin in the presence of various emulsifying soluble solids were in some cases mobile, in others rigid. The existence of such mobility showed that Bancroft's theory that stabilisation of emulsions was effected by a *continuous* emulsifying shell with two different surface tensions on its two faces was in need of important modification.

In cases where the emulsifying substance consisted of insoluble solids in fine suspension, evidence was given that the chief factor determining which of the two liquids became dispersed in the other was the angle of contact formed between the liquid-liquid interfaces and the sides of discrete solid particles. Methods were given for ascertaining in which of the two liquids the angle of contact was obtuse, and it was found that in every case it was this liquid which became dispersed in the other.

The demonstrations, given by Prof. W. Ramsden and Miss A. Mackenzie, to illustrate experiments on surface-films, were very beautiful. One simple experiment to illustrate the rigidity of surface-films in certain cases can easily be repeated by any one : a light magnet is floated on the surface of a saponin solution, and an ordinary pivoted magnetic needle immersed in the same solution. On bringing a magnet near to the vessel, the surface magnet remains stationary, while the immersed one follows the movements of the magnet outside just as readily as it would do in air.

As Prof. Donnan pointed out in his presidential address to the Section of Chemistry, many substances spread on water surfaces to a stable film, one molecule thick. All the molecules appear to be oriented parallel to one another and perpendicular to the surface. Mr. N. K. Adam, who has employed this method for the determination of the cross-sectional area of molecules, gave a demonstration at the scientific soirée of the method of procedure. He has been able further to show that these surface films possess, according to the conditions, the properties of solids, liquids, or gases, a fact of the greatest theoretical significance.

THE PROPERTIES OF MEMBRANES.

A joint discussion on "The Physical Chemistry of Membranes in Relation to Physiological Science" was held by the Chemistry and Physiology Sections, and was opened by Prof. H. E. Roaf. A membrane was defined as a structure separating two phases ; it might be semi-permeable or show permeability of varying grade, and the presence of the membrane made it necessary to consider the possibility of the occurrence of filtration, osmosis, electro-endosmosis, and other related phenomena, for the membrane limited diffusion and allowed differences of concentration of solutes on its two sides, giving rise to various osmotic and electrical phenomena. Physiology was largely concerned with the problem of the passage of material across physiological membranes : as example of these the lungs, intestine, kidney, and salivary gland might be taken.

In the lungs, there appeared to be no certain evidence that the membranes which had to be traversed by the gases entering and leaving the blood did anything but slightly hinder diffusion—the state of equilibrium between blood and air was almost attained, and oxygen never reached a higher partial pressure in the blood than in the air, nor did carbon dioxide ever have a greater pressure in the air of the alveoli than in the blood. Diffusion was adequate to explain not only the partial pressures found in blood and air, but also sufficed to account for the total amounts of oxygen and carbon dioxide traversing the membrane under all conditions.

The passage of substances across the membrane of the intestine offered a much more difficult problem, and one towards the solution of which we had made much less progress, for here many facts seemed to be in opposition to the view that mere diffusion was the chief or even an important factor. When the epithelium was removed from the mucosa of the small intestine, for example, absorption of its contents into the blood was slower, not quicker. Again, blood plasma could be absorbed completely from the lumen of the bowel into the blood, in spite of the apparent identity of the contents with the fluid part of the blood. Finally, when absorption took place from the bowel, the oxygen usage of the bowel had been stated to be increased, *i.e.* more work was being done by it under these conditions.

The kidney and the salivary gland presented equal difficulties ; that considerable work was done by the kidney in concentrating those blood constituents which were excreted, was indisputable. Similarly, the salivary glands could not act by any mere filtration, because, apart from the chemical differences between the blood and the saliva, there was the fact that the pressure reached in the salivary ducts when the flow was stopped by occlusion was, as Ludwig showed, much greater than the maximum arterial

pressure; one theory which had been advanced to explain this was that the secreting alveolus acted as an osmometer, and attracted fluid from the blood, but this theory leaves us still in somewhat of a dilemma. Some cells, such as the red blood corpuscles, appear to have membranes at their surfaces, but others do not; if an amœba be stained with an intra-vitam dye, the dye does not escape into the surrounding water when the surface of the amœba is punctured.

Prof. F. G. Donnan spoke of membranes from the physico-chemical aspect, but exhibited a good deal of sympathy and interest in the biological side of the question, which he described as one of the most important issues concerned with these physico-chemical studies. The fact that membranes might be living structures might alter all physico-chemical conceptions, particularly those based on the study of states of thermodynamic equilibrium. Living organisms utilised an environment not in such an equilibrium, were transformers and consumers of free energy, and environmental equilibrium meant non-activity and eventual death. Energy potentials might run up in one place and down in another, so that interpretations would be difficult. After referring to the thermodynamic aspect of osmotic pressure, Prof. Donnan reviewed some of the theories which had been advanced in explanation of the properties of membranes. The sieve theory, according to which a semi-permeable membrane acted merely as a sieve, was rather discredited: some form of adsorption theory seemed more attractive; for example, if a substance is negatively adsorbed, it will be repelled from the walls of the pore, so that pure solvent alone passes through. As a modification of this we have various views of ionic adsorption which are capable of explaining many facts. The formation of a Helmholtz double layer on the walls of the pore would explain why the mobility of one ion can be reduced more than that of the other. Different concentrations of electrolyte on the two sides, or a different mobility of ions, would cause a flow by producing electro-endosmosis. The alteration effected in liquid-liquid potentials when a membrane was interposed might also be explained on similar lines. (A separate paper contributed to the discussion by Dr. E. B. R. Prideaux also dealt with membrane potentials considered as diffusion potentials.) The product of the activities of two ions on either side of a membrane permeable to both were the same—this is the explanation of the facts of membrane equilibrium (Donnan equilibrium), and is of considerable importance to physiology. The explanation of differential permeability, as given by Meyer and Overton, was that one of the constituents was soluble in the substance of the membrane, while the other was not; this view is not acceptable to physical chemists. Also, the suggestion of Clowes, that the reversal of phase in a membrane of emulsoid structure might explain a changed permeability of membranes, cannot be entertained.

Science and Social Service.

THE presidential address delivered by Sir George H. Knibbs at the New Zealand meeting of the Australasian Association for the Advancement of Science in January 1923, entitled "Science and its Service to Man," reviews the recent advances in the fields of astronomy, relativity, atomistics, radioactivity, spectroscopy, and various branches of chemistry, including biochemistry, metallurgical chemistry, and a number of technical applications of synthetic chemistry. There is a brief notice of the Rutherford-Bohr theory of atomic structure, and the properties of colloids and of vitamins are discussed, together with the functions of the ductless glands, and their relation to human development. The following extracts from the address are of particular interest:

The highest product of civilisation is not the mere maintenance of man on the planet, but such maintenance as makes him a student of that vast universe of which physically he forms so utterly insignificant a part—a student, developing faculties by means of which he can appreciate beauty, magnificence, majesty, and, indeed, the whole range of things spiritually apperceived or intellectually grasped—a student capable of solving the most apparently hopeless problems.

Nevertheless, in addition to these intellectual gifts, the proper study of science may result in important material advantages. At the same time it must be recognised that scientific advance has introduced previously unsuspected dangers; and while it is essential that nations which desire to preserve their independence should study the application of science to warfare, the terrible weapons which modern discovery places in the hands of unscrupulous nations, and the devastating nature of modern warfare, cause one to tremble for the future history of mankind if means cannot be found to eliminate the evil. Vital statistics clearly show that, with the present normal rate of growth of populations, the world will, in a comparatively short period, become incapable of supporting its teeming millions, in spite of the possibilities of increasing the productivity of the soil.

The overspill of dense populations provokes situations from which apparently there is no escape, for it involves agreement as to expansion, and the much-discussed question of birth control has to be seriously considered. A review of the whole realm of Nature warns us that there *may* be no way of escaping the great issue. May it not be then accepted that, as long as human nature is what it is now, war is certain, even if it be not inevitable. The way *could* come in peace, but only through a world-wide discipline, vastly more thoroughgoing than any discipline we dream of at present.

The address concludes with a plea for the creation of a national appreciation of science, for improvement of scientific education, and for the development of research.

"Our hope is to see a new spirit born here. No one knows what lies on the knees of the gods. But there is something within the mind and heart of any great people which responds to the dream of excellence, and inflames when the vision of national destiny is before it. Our Mother-land has had a great past. Is its offspring here in southern seas, illumined by 'the gem pointed cross and the blazing pomp of Orion,' to rise to material, to intellectual, and to moral greatness among earth's peoples? If so, the path is strenuous, but glorious. All visions of ease and luxury are but opiates, and lead to destruction. We shall need to gird ourselves for the task, and create for ourselves a world where our sons, knowing something of the splendid mysteries of the boundless universe, and also of our own little world, will excel in the art of using to the full the heritage our nation has given us. Then indeed will science have rendered noble service to the sons of Australasia."

The Frenophone.

A NOVEL form of telephone receiver, called the Frenophone (Fig. 1), the invention of Mr. S. G. Brown, has been exhibited recently at the Royal Society conversaziones and at the Exhibition of Scientific Apparatus held in connexion with the British Association meeting at Liverpool. Its chief feature is the amplification of weak signals to great loudness without loss of purity in the rendering. It is thus of especial value in wireless telephony, such as broadcasting, where singing and orchestral music must be faithfully reproduced without the sort of distortion associated with inferior gramophones.

This novel "loud speaker" depends for its operation upon the high degree of friction existing between a moving surface of optical glass and a pad of cork

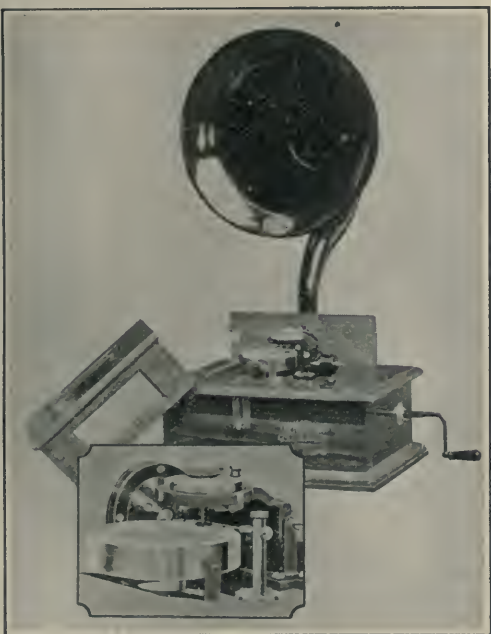

FIG. 1.—The Frenophone. Inset, enlarged view of the revolving glass disk with cork friction pad.

or similar substance. The coefficient of friction, especially when the glass surface has been lightly treated with a tacky compound, is so high that very slight changes in a constantly applied pressure between the pad and glass produce enormous fluctuations in the tangential drag between them.

In practice, the glass surface is made in the form of a disk revolved slowly by a gramophone clock. The pad consists of a small steel disk faced with thin cork. The pad is laid upon the glass, its back being pressed upon by a light, flexible pin which, in turn, is fastened to the reed of a Brown telephone headpiece receiver. The pad is linked by "reins" to the diaphragm, which is of the usual loud-speaker type, and is fixed at the base of a trumpet.

Speech currents in the receiver coils actuate the reed, setting it in vibration. These vibrations, imparted to the pad, appear as oscillatory changes of the steady pressure of the pad on the glass disk. Corresponding large changes of the pull of the pad, by its reins, upon the diaphragm result in great amplification of the speech emitted from the trumpet. The great merit of the instrument, as compared with other forms of loud speaker, is the combination of loudness with purity; the sounds of the various musical instruments are individualised with absolute fidelity to the original.

University and Educational Intelligence.

BELFAST.—Mr. R. W. Livingstone has been appointed vice-chancellor of the Queen's University. Mr. Livingstone, who is tutor and librarian of Corpus Christi College, Oxford, is the author of various publications in defence of classical education.

CAMBRIDGE.—Mr. E. W. Rice, junior, honorary chairman of the General Electric Company, Schenectady, New York, has sent on behalf of his board of directors "a check for five thousand dollars" to Sir Ernest Rutherford, to use to advance the work over which he presides. The gift to the Cavendish Laboratory is in appreciation of the debt which the General Electric Company owes to the Cavendish professor and his co-workers in scientific research. Mr. H. C. Levis, chairman of the British Thomson-Houston Company, has sent a cheque for 250*l.* for a similar purpose. These gifts will be used to supplement existing resources for research in the Cavendish Laboratory.

Mr. M. Dixon, Emmanuel College, has been appointed senior demonstrator in biochemistry.

GLASGOW.—The subject for the essays to be sent in competition for the Thomson prize in geography for the session 1923–4 is "Dwellings in Lands of Equatorial Climate: their Types, Materials, and Geographical Distribution." The competition is restricted to matriculated students of the university for the session 1923–4. The latest date for the receipt of essays is October 20, 1924. Each essay must be distinguished by two mottoes, accompanied by a sealed letter bearing on the outside the same mottoes, and containing a declaration subscribed by the author that the essay is entirely his own. They should be sent to the Clerk of the Senate.

LONDON.—Mr. Geoffrey E. Duveen has given the sum of 10,000*l.* for the establishment of a University lectureship in otology.

The title of reader in plant ecology has been conferred on Dr. E. J. Salisbury of University College.

The following doctorates have been conferred: *D.Sc. in Chemistry:* Mr. R. Ray (University College), for a thesis entitled "Studies on Boron and Silica"; and E. W. J. Mardles, for a thesis entitled "A Contribution to the Theory of Colloidal Chemistry based on Studies in the Colloidal Chemistry of Cellulose Derivatives," and other papers. *D.Sc. in Physics:* Mr. H. P. Waran (University College), for a thesis entitled "Disintegration in Discharge Tubes." *D.Sc. (Economics):* Mr. H. Finer (London School of Economics), for a thesis entitled "Representative Government, and a Parliament of Industry."

MANCHESTER.—The following are among the persons on whom the new chancellor, the Earl of Crawford and Balcarres, will confer honorary degrees on the occasion of his installation on November 10: Mr. J. G. Adami, vice-chancellor of the University of Liverpool, Sir James G. Frazer, Sir Arthur Keith, and Sir Thomas H. Warren.

OXFORD.—By the recent death of Dr. A. Rambaut, the post of Radcliffe observer becomes vacant. It was in memory of Manuel Johnson, one of Dr. Rambaut's predecessors, that the Johnson memorial prize was founded. This prize is usually offered every four years for an essay on some astronomical or meteorological subject. It has been awarded this year to G. M. B. Dobson, Lincoln College.

The Burdett-Coutts scholarship in geology has been awarded to L. F. A. Edgell, University College.

The Halley lecture for 1924 will be delivered by Prof. John Joly, professor of geology and mineralogy, Trinity College, Dublin.

THE University of King's College, Windsor, Nova Scotia, is to be moved to Halifax. A large part of its buildings was destroyed by fire in 1920, and its work has since been carried on with much difficulty in cramped and uncomfortable quarters. The Carnegie Corporation of New York will make a large grant towards the expenses of re-establishing the college at Halifax, where its work will be carried on in association with the University of Dalhousie. Its engineering courses will be discontinued.

IN accordance with the terms of the will of the late Sir Archibald Dawnay, the Royal Institute of British Architects has awarded one scholarship of 50*l.* per annum to Mr. R. W. Donaldson (University of Liverpool), and two scholarships of 25*l.* per annum each to Mr. R. H. Turner (University of Liverpool) and Mr. A. E. Cameron (Architectural Association). Mr. C. H. Hutton (University of Liverpool), who was awarded a scholarship of 25*l.* for 1922–1923, has been granted a renewal of his scholarship for 1923–1924. The scholarships are intended to foster the advanced study of construction and the improvement generally of constructional methods and materials and their influence on design.

A PRIZE fellowship of 1000 Swedish kronor, offered for research in science by the Swedish Federation of University Women, has been awarded to an Englishwoman, Mrs. Muriel Wheldale Onslow. Mrs. Onslow is distinguished for her work on the biochemistry of plants. She has already been an "N" Fellow of Newnham College, Cambridge, and in 1915 was awarded a fellowship of the British Federation of University Women. The Swedish award proves that the work of British women in science is noteworthy not only in Great Britain but also in competition with that of other scientific workers, for the fellowship was open to the university women of eighteen countries.

A LIST of qualifications for teachers in technical schools recognised by the Burnham Committee for salary purposes as equivalent to a degree has been approved by the Board of Education, and has recently been issued as Appendix III. to the Report of the Standing Joint Committee on Salaries for Teachers in Technical Schools. (H.M. Stationery Office: Imperial House, Kingsway, London, W.C.2. 1*d.* net. By post, 1½*d.*) In Section (*c*) Science and Technology the following qualifications are accepted:—(i.) *Academic Qualifications:* Associate of the Royal College of Science, London or Ireland, of the City and Guilds of London Institute, or of the Royal School of Mines; (ii.) *Membership of Professional Societies:* Associate membership of the Institutions of Civil Engineers, Mechanical Engineers, or Electrical Engineers, provided that the Associate Membership Examination has been passed, and that three years' engineering experience after the age of 21 is reckoned as part of the qualification; associateship of the Institute of Chemistry, provided that the Institute's Examination for Associateship has been passed; and membership of the Pharmaceutical Society and Pharmaceutical Chemist, provided that the Qualifying and Major Examinations have been passed, and followed by three years' professional experience; (iii.) *Miscellaneous:* Whitworth scholarship if gained between 1887 and 1922; and the first-class Colliery Managers' Certificate if the holder has three years' industrial experience after the age of 21, and has also obtained the diploma of a recognised mining college. This list may be modified from time to time, and qualifications not included can be submitted to the Board of Education by Local Authorities for approval.

Societies and Academies.

PARIS.

Academy of Sciences, October 8.—M. Albin Haller in the chair.—A. **Lacroix**: Notice on P. Elie Colin. The greater part of Colin's life was spent in Madagascar, where his work in geodesy, meteorology, and magnetism formed the foundation of all subsequent work in these subjects in the island.—Jean **Perrin**: Radio-chemistry of fluorescence. The theory developed in an earlier communication is modified to agree with the observation that in certain cases the fluorescent body may enter into chemical combination with the solvent (glycerol) or with oxygen. The influence of temperature on photo-chemical reactions is also investigated.—Ch. **Depéret**, F. **Arcelin**, and L. **Mayet**: The discovery of fossil remains of man of the Aurignacian age at Solutré (Saône-et-Loire). Three complete skeletons were discovered in positions which definitely prove burial. Drawings of the three skulls, with descriptions, are given. The men belonged to the Cro-Magnon race, Aurignacian period, but differ in some respects from the Cro-Magnons of Vézère and Grimaldi.—Alex. **Véronnet**: The formation of planetary systems and stellar systems.—R. **Fortrat** and P. **Dejean**: An attempt to construct a bobbin without iron giving intense magnetic fields. The solenoid was constructed of wires of electrolytic copper, rectangular in section, cooled by a rapid current of water. The apparatus as made could carry a current of 4740 amperes and absorbed 277 kilowatts. A field of more than 40,000 gauss was obtainable.—Louis **de Broglie**: Quanta, the kinetic theory of gases and Fermat's principle.—L. P. **Clerc**: A question of photographic perspective.—Albert **Portevin**: Remarks concerning the relation between Young's modulus and the atomic volume. The equation expressing the relation between Young's modulus, the density and the atomic mass given in a recent communication by Th. Peczalski is identical with results arrived at by Fesserden in 1892. There is approximate agreement between the formula and experiment for certain metals, but for others, notably rhodium, tantalum, and tungsten, there are wide discrepancies, tungsten, for example, giving 42·2 as the modulus against 8·0 calculated.—P. **Vaillant**: The influence of small variations of temperature on the conductivity of solid salts and the rôle of the humidity in this phenomenon. The results of the experiments described lead to the conclusion that in solid salts the electrical conductivity is largely superficial and due to a particular condition of the surface layer. This accounts for the marked influence of traces of moisture on the observed conductivities.—V. **Sorrel**: Polarisation capacities with alternating currents.—Marc **Bridel**: Biochemical study on the composition of *Monotropa hypopitys*. Isolation of a new methyl salicylate glucoside, monotropitine. The extracts of this plant contain two glucosides, monotropeine and monotropitine, the latter being new: they are readily separated by their different solubilities in acetic ester. The new glucoside, monotropitine, has been isolated in the pure, crystalline state. Some physical and chemical properties are given: it does not appear to be identical with gaultherine.—René **Wurmser**: Energy yield and chlorophyll assimilation.—A. **Maige**: Remarks concerning the formation and digestion of starch in plant cells. The theory best in accord with known facts on the formation and digestion of starch in plants consists in regarding these two phenomena as due to entirely distinct catalytic actions.—G. **Truffaut**

and N. **Bezssonoff**: The influence of the sugar concentration of the media on the activity of nitrogen fixing bacteriă. Both for the development of the aerobic bacilli in a non-nitrogenous medium and for the fixation of nitrogen in those possessing this property, low sugar concentrations of the order of 1 in 1000 are more advantageous than those usually employed.—M. **Lemoigne**: The butyleneglycollic fermentation of calcium lactate by bacteria of the *B. subtilis* group. The formation of 2-3-butyleneglycol and acetylmethylcarbinol by the action of bacteria of the *B. subtilis* group on calcium lactate has been proved. The action is slow and difficult to detect.—H. **Barthélémy**: The action of water, common salt, sodium bromide, and calcium chloride on the spermatozoids of *Rana fusca* and *Bufo vulgaris*.—A. **Weber**: Does the rupture of the branchial operculum at the moment of metamorphosis of Batrachians demonstrate the transmission of an acquired character?

VIENNA.

Academy of Science, July 12.—R. Wettstein, president, in the chair.—Fritz **Früchtl**: A contribution to the knowledge of the qualitative and quantitative distribution of Copepoda in the Plankton of the North Adriatic and of their ectoparasites. The use of graphic representation in distribution-maps.—Gerhard **Kirsch** and Hans **Pettersson**: On the destruction of atoms by α-particles. A study of the H-particles produced when atoms are destroyed by swift α-particles. The ranges of the atomic fragments (H-particles) are 18 cm. for beryllium, 12 cm. for silicon, 13 cm. for magnesium in air. The ratio between the H-particles produced and the number of α-particles employed is about 10^{-5} for beryllium, 6×10^{-6} for silicon and magnesium.—J. **Hepperger**: On the heliocentric velocity of meteors. Theoretical representation of the relative numbers of the frequency of meteors. Assuming the heliocentric velocity of the meteors to amount to 74 km. per second, the number of meteors per hour ascertained by observation may be made to agree with the relative numbers.—Julius **Zellner**: Contributions to comparative phytochemistry. Chemical analysis of the leaves and flowers of *Knautia sylvatica*.—Konstantia **Püringer**: Chemical analysis of the leaves and flowers of *Chamænerion angustifolium*. Quantitative determinations show agreement in constitution for leaves and flowers.—Chaja **Feinberg**, Johann **Herrmann**, Leopoldine **Rögelsperger**, and Julius **Zellner**: Chemical analysis of the bark of *Acer campestre*, *Corylus Avellana*, and *Alnus incana*.—Josef **Einleger**, Jolanthe **Fischer**, and Julius **Zellner**: Chemistry of heterotrophic Phanerogamia. Loranthus was chemically analysed for the first time. Elements have been found in Viscum not previously recognised.—Hans **Przibram** (1): A critique of the transplantation experiments made by R. G. Harrison. The rudiments of the anterior limbs of axolotl embryos, if excised and implanted in the same or neighbouring situations upside down (with dorsal and ventral surfaces reversed), develop into extremities which have the symmetry of limbs belonging to the opposite side of the body. These experiments do not prove a change of the upper side of the rudiment into an under side by the influence of the body as a whole. It is an inversion of the polarity of the extremities, which grow proximally instead of distally. The inversely transplanted rudiment is impeded in the original direction of its growth by the adjacent parts of the body. (2) The causes of animal colouring. The presence of "dopa" (3, 4-dioxyphenylalanin) in the cocoons of night-butterflies and saw-flies causes spontaneous formation of melanine when water is admitted. While in the case of day-butterflies the sensitiveness to light of the tyrosinase-ferment plays a part in the adaptation to the brightness of the background, the adaptation of the night-butterflies is caused by the degree of moisture. The cocoons acquire a dark colouring on a moist, dark background.—Alfred **Ehrenpreis** (1): Curvature of the neck of the larva when the animal pole of the ovum of *Triton alpestris*, Laur., has been punctured. By puncturing the animal pole of fertilised, but still unsegmentated, ova of *Triton alpestris*, Laur., Przibram's hypothesis has been confirmed that the prospective signification of the animal half of the ovum is in the formation of dorsal parts of the embryo. An animal developed so far as to form a larva, after puncture had its head bent dorsally at almost a right angle, owing to a deep indentation in the neck due to the puncture. (2) Transplantation of the sperm of full-grown Urodelæ. Successful transplantation of the whole sperm of *Triton Cristatus*, Laur., by the autophorous method of Przibram. The transplanted spermatozoa were in good condition even four months after the operation; their functions were normal. The formation of the spermatophore was completed in eighteen days.—August **Jellinek** and Theodor **Koppanyi**: Mental capacity of rats with an injured brain. Kinæsthetic and optical experiments in training rats, the cortex of the cerebrum of which had been destroyed by thermo-cautery, proved that the associative memory of the rats is to a very large extent independent of the cortex of the cerebrum.—Sato **Kunio** and Leonore **Brecher**: The causes of animal colouring. In vertebrates it is probably the tyrosine in the teguments and dermal coverings that supplies the chromogen. "Dopa," as the element of pigment formation, could not be found in fish, birds, and mammălia.—Leonore **Brecher** and Ferdinand **Winkler**: The agreement of positive and negative "dopa"-reactions both in frozen sections and extracts. Frozen sections of rats' eyes, of the scalp of dark-haired men, of the chrysalis of *Vanessa urticæ*, and the cocoon *Bombix mori* did not show any "dopa" reaction; "dopa" was found, however, both in frozen sections of the cocoons of *Saturnia pavonia* and *Erigaster lanestris* and in their extracts.—Walter **Finkler**: (1) Reflex action to absence of moisture of the marsh toad, *Bombinator igneus*, Laur. On dry, clayey soil the toad remains stationary; the hind-legs only make an irregular alternating movement, which is a reflex action, probably in order to save itself from drying up and to get to the deeper, moister layers of earth. On dry ground the toads also lose the reflex of turning round. (2) The influence of external factors on the colour of the iris of marsh toads, *Bombinator igneus*, Laur. The golden colour of the iris of animals kept on moist ground or moss does not change. The iris of toads kept in aquaria becomes whitish when they are illuminated by a mirror from below; the iris acquires a green metallic lustre when the animal is kept on dry ground. When no light is admitted the iris does not change its colour. (3) Experimental variation of the colour of the skin of toads, *Bombinator igneus*, Laur., and *Bombinator pachypus*, Br. If the upland toad is kept on dry clay, light green spots appear on its back, resembling those of the marsh toad. Grey marsh toads turn green on moist clay; when kept in water and illuminated from beneath, a golden colouring with a metallic lustre appears on the two parotids, reminding one of the bronze metallic lustre of the ground-colour found in upland toads.

Diary of Societies.

MONDAY, NOVEMBER 5.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Geophysical Discussion: Turbulence in Tidal Motions: Prof. J. Proudman, G. I. Taylor, and Dr. H. Jeffreys (Chairman, Dr. H. Lamb).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Monthly Meeting.

SOCIETY OF ENGINEERS, INC. (at Geological Society), at 5.30.—W. Lee: Lubrication.

INSTITUTE OF TRANSPORT (Annual General Meeting) (at Institution of Electrical Engineers), at 5.30.—T. Salkield: A Transport Adventure in Persia.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—Dr. A. Russell and others: Discussions on Engineering Training.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Prof. T. P. Nunn: Scientific Objects and Common-Sense Things (Presidential Address).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—Dr. G. W. Monier-Williams: The Use of Hydrogen Cyanide for the Fumigation of Ships.

ROYAL INSTITUTE OF BRITISH ARCHITECTS (at 1 Wimpole Street), at 8.30.—Presidential Address.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Col. J. C. B. Statham: From Mossamedes to the Victoria Falls.

TUESDAY, NOVEMBER 6.

INSTITUTE OF HYGIENE, at 3.30.—Dr. J. Fenton: Preservatives and Adulterants in Foods.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. C. J. Singer: The History of Anatomy (FitzPatrick Lectures) (1).

MINERALOGICAL SOCIETY (at Geological Society of London) (Anniversary), at 5.30.—Dr. L. J. Spencer: Euclase and Platinum from Diamond Washings in British Guiana.—H. E. Buckley: The Anomalous Optical Properties of Freshly Prepared Mixed Crystals of Seignette Salt.—Col. N. T. Belaiew: The Genesis of Widmanstätten Structure in Meteorites and Terrestrial Alloys.—Prof. L. R. Wilberforce: Illustration and Detection of Inclined and Horizontal Dispersion in Bi-axial Crystals.—A. Russell: The Occurrence of the Rare Mineral Nadorite in Cornwall, and of Beraunite (Eleonorite) in Co. Cork, Ireland.—A. F. Hallimond and F. R. Ennos: Moravite from North Wales.—Dr. G. T. Prior: The Chemical Composition of the Ashdon Meteorite.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—F. A. Mitchell-Hedges: The Primeval Jungle of Panama.—G. H. Goldfinch: Notes on the African Crested Rat (*Lophiomys imhausi*).—H. G. Jackson: A Revision of the Isopod Genus *Ligidium* Brandt (Crustacea).—I. G. S. Montagu: Some Mammals from Jugo-Slavia.—I. G. S. Montagu and Grace Pickford: The Guernsey *Crocidura*.—Major S. S. Flower: Additions to the Snake Fauna of Egypt.—S. Hirst: Some New or Little-known Species of Acari.—Dr. C. F. Sonntag: The Pelvic Muscles and Generative Organs of the Male Chimpanzee.

INSTITUTION OF CIVIL ENGINEERS, at 6.—Sir Charles Langbridge Morgan: Presidential Inaugural Address and presentation of Medals.

INSTITUTION OF MARINE ENGINEERS, INC., at 6.30.—R. J. McLeod and T. Calderwood: Gear Cutting.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. D. Johnston: Presidential Address.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Miss M. A. Murray: Excavations in Malta.

RÖNTGEN SOCIETY (at Institution of Electrical Engineers), at 8.15.—Sir Oliver J. Lodge: X-rays and the Atom (Presidential Address).

WEDNESDAY, NOVEMBER 7.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—The late R. W. Hooley: The Skeleton of *Iguanodon atherfieldensis* sp. nov., from the Wealden Shales of Atherfield (Isle of Wight) (read by Dr. A. Smith Woodward).—Prof. S. H. Reynolds: The Igneous Rocks of the Tortworth Inlier.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—E. H. Shaughnessy: Chairman's Inaugural Address.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS, INC. (at Engineers' Club, Coventry Street), at 7.—F. G. Whipp: Some Common Faults in Fan Design and Application.

ENTOMOLOGICAL SOCIETY OF LONDON, at 7.

ROYAL MICROSCOPICAL SOCIETY (Biological Section), at 7.30.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—D. Rattonji Nanji and W. S. Shaw: A Quantitative Study of the Limitations of the Reaction between Ammonia and Sodium.—Phyllis H. Price: The Gold-Beaters' Skin Test for Tannins.—W. Donovan: Determination of Nitrogen in Coal.—J. C. Thresh: The Estimation of Lead in Water and Urine.

ROYAL SOCIETY OF ARTS, at 8.—Lord Askwith: Exhibitions.

THURSDAY, NOVEMBER 8.

ROYAL SOCIETY, at 4.30.—A. S. Parkes: Studies on the Sex-ratio and Related Phenomena—Fœtal Retrogression in Mice.—R. A. Fisher: The Influence of Rainfall on the Yield of Wheat.—(To be read in title only.) D. Thursby-Pelham: The Placentation of *Hyrax capensis*.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. C. J. Singer: The History of Anatomy. (FitzPatrick Lectures) (2).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—W. G. Spencer: Melanosis (Melanin, Melanoma, Melanotic Cancer) (Bradshaw Lecture).

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. Jessie White: Auto-Education.

CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 8.—Dr. J. H. Jeans: Van der Waals Memorial Lecture.

INSTITUTE OF METALS (London Local Section) (at Royal School of Mines), at 8.—Dr. W. Rosenhain; Some Impressions of American Non-ferrous Metallurgy.

FRIDAY, NOVEMBER 9.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Dr. J. H. Jeans: The Mechanism and Structure of Planetary Nebulæ.—S. R. Pike: The Development of Faint Images by Fogging.—W. M. Smart: The Proper Motion of a Faint Star near η Cassiopeiæ.—B. Lindblad: The Intensity-Distribution in Short Grating Spectra and Objective-Prism Spectra as a Function of Spectral Type and Absolute Magnitude.—R. Stoneley: The Elastic Yielding of the Earth.—Sir George Greenhill: The Time or Mean Anomaly in a Newton-Einstein Orbit and Allied Astronomical Problems.—W. F. Denning: (*a*) Stationary Meteors and Meteors nearly Stationary observed at Bristol since 1879; (*b*) Radiant Points of Meteors, 1912-1923.—W. S. Franks: The Relation between Visual Star Colours and Spectral Classes.—F. H. Seares: A Troublesome Systematic Error.—Roy. Obs. Greenwich: Mean Areas and Heliographic Latitudes of Sunspots in the year 1922.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—Dr. A. Ferguson: The Measurement of the Surface Tension of a Small Quantity of Liquid.—Prof. A. L. Narayan: The Scattering of Light by Carbon Dioxide, Nitrous Oxide, and some Organic Vapours.—Sir Richard Paget, Bart.: A Demonstration of Experiments with Models for the Reproduction of Vowel Sounds.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Sir Alexander C. Houston: The Application of Photography to the Problems affecting Water Supply.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—Dr. C. E. K. Mees: Amateur Cinematography.

PUBLIC LECTURES.

SATURDAY, NOVEMBER 3.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. C. A. Raisin: Volcanoes.

MONDAY, NOVEMBER 5.

UNIVERSITY COLLEGE, at 5.—J. W. Jeaffreson: The Analysis of Stress-Accent by the Methods of Experimental Phonetics.

VICTORIA LEAGUE (at 22 Eccleston Square), at 5.—Lt.-Col. M. C. Nangle: Burma.

TUESDAY, NOVEMBER 6.

UNIVERSITY COLLEGE, at 5.30.—J. H. Helweg: Daily Life in the XVIth Century as depicted by the Historian, Troels-Lund. (Succeeding Lectures on November 13, 20, 27, December 4 and 11.)

WEDNESDAY, NOVEMBER 7.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—W. A. Bullough: Problems of Health Science in Rural Districts.

UNIVERSITY COLLEGE, at 5.30.—J. C. Gröndahl: The Work of Henrik Wergeland: Creation and Man. (Succeeding Lectures on November 14, 21, 28, December 5 and 12.)

THURSDAY, NOVEMBER 8.

GUY'S HOSPITAL MEDICAL SCHOOL, at 5.30.—Prof. E. W. Hey Groves: The Treatment of Injuries of the Long Bones produced by Accident or Disease. (Succeeding Lectures on November 9, 12, and 13.)

UNIVERSITY COLLEGE, at 5.30.—Chevalier T. Sambucetti: Italy and Europe (League of Nations Union Lecture.)

FRIDAY, NOVEMBER 9.

UNIVERSITY COLLEGE, at 5.15.—Prof. J. C. Drummond: Vitamins.

KING'S COLLEGE, LONDON, at 5.30.—C. E. M. Joad: The Philosophical Background of Music and Poetry: (1) The Function of Poetry.

UNIVERSITY COLLEGE, at 5.30.—R. H. Hooker: The Effect of the Weather on the Crops (Jevons Memorial Lectures). (Succeeding Lectures on November 16, 23, and 30.)

ROYAL SOCIETY OF ARTS, at 8.—Major H. Barnes: Hygiene and Architecture: (1) Preventive Hygiene: Health and Town-Planning (Chadwick Lectures).

SATURDAY, NOVEMBER 10.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. H. S. Harrison: Fashion among Savages.

The Imperial Institute and the Development of Overseas Resources.

THE Imperial Economic Conference has approved a scheme whereby the Imperial Institute is to be reconstituted; a representative of the Department of Scientific and Industrial Research is to be one of a committee of three appointed to see that the Institute laboratories limit their work to preliminary inquiries, and the Galleries are to be closed, in spite of the protest of New Zealand, on the score of economy. The detailed account which has just been issued by the Imperial Institute (Bulletin of the Imperial Institute, vol. xxi., No. 1, pp. iv + 289, price 3*s*. 6*d*.) of its work in recent years has been published at a very convenient time. The Institute was founded in 1887, but until 1903 the work for which it was established was subordinated to the effort to run it as a social club attached to a ballet. It was reorganised in 1903, and in that year it began the publication of its quarterly Bulletin, which now has a circulation of 3000 copies, and also issued the first report by its Mineral Surveys. Its efforts then to undertake the work for which it was founded were handicapped by restrictions, burdens, and prejudices inherited from the former regime. The Institute has, however, been steadily surmounting these difficulties and building up an organisation by which to help the utilisation of the varied materials still lying unused in the Empire Overseas. It works by three main branches. Its Department of Scientific and Technical Research investigates all kinds of raw materials and advises as to their profitable employment. Its Intelligence Department gives information and advice, and is aided by committees of commercial, technical, and scientific experts, which deal with raw materials, silk production, rubber research, timber, and the mineral resources of the Empire. The extensive museum attractively displays the chief raw materials and illustrates the geographical conditions under which they are produced and the processes by which they are utilised.

The work already achieved by the Institute is clearly of high value. The discovery of the Udi coalfield by one of its Mineral Surveys would alone repay all the expenditure on the Institute; for that coalfield, in the event of any serious war in north-west Africa, would be invaluable in the defence of our colonies there, and it will probably develop into a coaling station of high importance from its position on the tropical Atlantic. The discovery of the monazite sands of Ceylon has destroyed the former German monopoly based on Brazilian material. Several of the Mineral Surveys organised by the Institute have now passed away from it, as they have developed into independent geological surveys.

As to other natural products, investigations in the

Institute laboratories or carried on elsewhere have removed from Indian beeswax the suspicion of adulteration that had arisen owing to its varied natural composition. The Institute has helped to render tobacco one of the chief crops of Nyasaland. It has shown why Indian barley to be serviceable for malting must be shipped from Calcutta by May and from Bombay by June. It has further helped India and the medical world by destroying the former monopolies held by Russia in santonin and by Germany in thymol. It has shown that for many purposes the kapok of India can be used instead of that yielded by a different tree from Java. It has assisted British Africa and the tanning industry by showing the value of the sant seeds of the Sudan and by finding British markets for South African wattle. Its work on the commercial production of acetophenone in Western Australia promises useful results. It has shown, in spite of the general view to the contrary, that Indian opium often contains a sufficiently high proportion of morphine and codeine to replace the supplies of Turkey and Persia which failed during the War. It has aided tea and rubber cultivation in Ceylon, and the Sudan by recognition of the special qualities of its gums. It has helped to improve the cocoa of West Africa and develop its palm oil production. It has secured the offer to Palestine of higher prices for Eri silk than those paid for the material elsewhere. It has shown that the *Croton Elliottianus* of Kenya Colony yields a valuable drug, and that the Indian aconites include several medicinal reagents, the production of which would be profitable to India and useful in medical practice. It has given helpful advice in fibre and bean production in East Africa, in wood pulp manufacture in Canada, and in connexion with the minerals, timbers, and drug-producing materials of Australia and New Zealand.

The Institute has been helpful not only by encouraging production, but also by avoidance of waste and disappointment in premature attempts to utilise materials in areas which cannot at present compete with more favourably situated localities. Meanwhile it collects information as to the position of such materials, so that they can be reconsidered from time to time as the conditions alter.

The work in the Exhibition Galleries of the Institute is not the least important of its services. The Imperial Conference has directed attention to the need for improved geographical education as regards the Empire. We referred in an article (April 1, 1922, p. 403) to the Public Exhibition Galleries of the Institute as "without question the finest illustration of economic geography in the world." All the chief materials of the Empire are shown there with ingenious illustrations of the volume of output, their distribution throughout the Empire, and the geographical conditions under which they occur. Important geographical features are illustrated by models, such as those of the Victoria Falls and of important harbours; ethnographical factors by models of different races; the scenery of different regions by pictures and photographs; local handicrafts by collections of work; and Oriental artistic culture by decorated pavilions such as those of India and Ceylon. Statues of Cook and Raffles direct attention to great landmarks in historical geography.

In addition to the public galleries there are research collections for reference by industrial experts and commercial inquirers. The galleries are unique as the only centre at which may be seen the opportunities and resources of all parts of the Overseas Empire. Although closed on Sundays, the galleries have 100,000 visitors a year and 10,000 school children go in classes under the guidance of their teachers and the Institute's lecturer. The loss of these galleries would be educationally deplorable.

The organisation of the Institute has proved well suited to its work. It is managed by an executive council, including representatives of the contributing states and colonies, with the Under Secretary of State for the Colonies as the chairman. This arrangement secures widespread but voluntary association, and the Institute organisation may prove a useful model on which still greater experiments in Imperial co-operation may be made.

That the Institute supplies a widely-felt need is shown by the numerous inquiries sent to it from all parts of the Empire. In 1922 it returned in replies no less than 1334 reports. The chief subjects, in order of number, were tropical agriculture, minerals, fibres, oils and oil-seeds, food-stuffs and fodders, timbers, drugs, and paper-making materials. That the information given by the Institute is of use to our larger Dominions as well as the smaller colonies is indicated by the widespread origin of the inquiries. They included in 1922, 121 from India, 89 from Australia, 89 from South Africa, 52 from Kenya Colony, 45 from Nigeria, 37 each from Ceylon and the West Indies, 36 each from the Gold Coast and New Zealand, 35 from Canada, and a few from each of the smaller colonies and protectorates.

It may be hoped that the reconstitution of the Imperial Institute will extend its usefulness and enable it to carry to full success the main purpose for which it was founded. The development of the natural resources of the Empire would then be assisted by investigation into the economic biology, geology, and geography of the British Overseas Dominions through an institution worthy of the group of national scientific museums at South Kensington.

Field Natural History.

(1) *Hebridean Memories.* By Seton Gordon. Pp. xii + 180 + 65 plates. (London, New York, Toronto and Melbourne: Cassell and Co., Ltd., 1923.) 15s. net.

(2) *Shetland Pirates and other Wild Life Studies.* By Frances Pitt. Pp. 248 + 16 plates. (London: G. Allen and Unwin, Ltd., 1923.) 10s. 6d. net.

IT used to be said of leisured Englishmen that their first thought of a morning was—" What shall we kill to-day ? " but in the present generation there is a steadily increasing number of men and women who prefer patiently to study wild animals in their haunts and to learn as much as possible about their character and habits. Instantaneous photography has added greatly to the interest and permanent value of this form of field sport, and both the books before me owe much to the camera.

FIG. 1.—Cock and hen great black-backed gulls. The cock is the larger and is calling. From "Hebridean Memories."

(1) Mr. Seton Gordon's field-studies have been conducted chiefly in the Highlands and Western Islands, where land and water retain much of their primitive aspect and still harbour creatures that have long been exiled from the low country. The hen-harrier—*Circus cyaneus*—for example, though practically extinct as a resident in the mainland, still rears its young in the Western Isles, although even there its survival is precarious. " It seems," says Mr. Gordon, " to be only a question of time before this handsome bird shares the fate of the kite and the white-tailed eagle, for even to its most inaccessible [least accessible ?] nesting grounds collectors make their way every year, and to a collector a clutch of hen-harrier's eggs is a prize of the first order."

Happily Mr. Gordon has something to set against this gloomy forecast. Until three years ago, the whooper swan—*Cygnus musicus*—had not been known to nest in Great Britain since the end of the eighteenth century; but on a certain loch which must remain, like the clan Macgregor, "nameless by day," a pair of whoopers reared their young in 1918 and 1919, and in 1920 two pairs nested there. " One nest," says the author, " is still intact as I write; the other has been robbed by collectors." As Christians we are bidden to love our enemies, but as sinful mortals it is something far removed from a blessing that we invoke upon these nefarious thieves. Unless vigorous measures are taken to protect the nests, we shall lose this splendid bird once more, owing to the perverse curiosity of a few armchair naturalists who will give ten times the price for a British-laid egg of a whooper than he will pay for one laid in Iceland.

Mr. Gordon pitched his tent—an inconspicuous one, no doubt—about fifteen feet from the whooper's nest,

and succeeded in getting some excellent photographs. He always entered the hide accompanied by his wife, who presently left it, rowing away from the island.

"It is useless to enter any hiding-tent unless one is accompanied by a companion, and unless that companion departs as ostentatiously as possible. All birds

Fig. 2.—The wild cat—expressions of the emotions.
1. Sulky. 2. Angry. 3. Furious.
From "Shetland Pirates and other Wild Life Studies."

can count *one*, but very few more than one; so a human figure leaving their nest stills their suspicions and causes them to return without delay, provided they have become accustomed to the presence of the hiding-tent, which should, if possible, be erected a few days previously."

Beasts as well as birds came under the author's scrutiny. The incident of a rabbit pursuing and driving away a stoat reminds me how, one summer evening, a large rat was driven close to my feet by a rabbit—presumably a doe protecting her young—was seized and severely shaken, and limped away squealing.

It surprises one that Mr. Gordon, who is at pains to defend the character of merlins, ravens and other birds of ravin, should repeat without comment what one would fain to be calumny against the dipper—*Cinclus aquaticus*. "It is said to do much harm when the sea-trout are spawning" (p. 51). We have the authority of the late Prof. Newton to the effect that "innumerable examinations of the contents of its stomach have not only proved that the charge [of devouring the ova of fishes] is baseless, but that the bird clears off many of the worst enemies of the precious product."

Mr. Gordon takes good note of the plants that grow in the waste places which he loves. The rose-root is recorded correctly as *Sedum rhodiola* on p. 21, and under the obsolete title *Rhodiola rosea* on p. 56. The illustrations throughout are admirable. The black-backed gulls, most ruthless of marauders, seem as harmless as doves in Fig. 1.

(2) The title of Miss Frances Pitt's volume "Shetland Pirates" is reminiscent of Magnus Troil and his daughters Minna and Brenda, but it is of feathered pirates only that she has to tell, namely, the great skua or bonxie—*Stercorarius skua*—and Richardson's skua or scootie—*S. parasiticus*. No doubt they live mainly by piracy, harrying gulls so cruelly that these have to disgorge their catch, and robbing the nests of other birds; but Miss Pitt charitably thinks that both species do occasionally fish honestly on their own account. These rapacious birds are described in the first chapter; each of the remaining chapters recording the author's observation of other birds and beasts, both in captivity and in the wild. She tells us how she used to declare that "there was no animal so wild that it could not be tamed by patience and kindness"; but her experience with a true wild cat—*Felis silvestris*—which she received as a kitten from Inverness-shire brought her to a different opinion, namely, that none of that species can be tamed or trained (Fig. 2).

One of Miss Pitt's most charming chapters deals with stoats and weasels; but I feel unable to share her doubts about the purpose of the white winter pelage assumed by both these little carnivores in northern regions, and by the stoat in parts of Great Britain. She cites the black tag on the stoat's tail as evidence against that purpose being protective coloration; but it is surely not more conspicuous than the white scut in the general protective colour of a rabbit. Miss Pitt's suggestion that a white coat better enables an animal to endure cold than a dark one receives no

support from the arctic fauna, for while the land mammals in polar regions are white in their snowy environment, the pelagic mammals — whales, seals, walrus, etc.—remain dark. The polar bear, hugest of Ursidæ, would encounter far more difficulty in stalking seals—his favourite food—were it not for his white mantle.

Miss Pitt has undertaken useful analysis of the barn owl's bill of fare. In twenty-eight pelts or castings taken at random from the roosting-place of a barn owl, she identified the remains of 112 small mammals and 3 small birds. "In less than a month that owl had eaten 66 mice and rats and 46 shrews, a record that I suspect few cats could equal." A cat, it may be noted, might kill the shrews, but would not eat them, therein showing a discrimination which it were well that gardeners and others would observe between the beneficent insectivore Sorex and the destructive rodents Mus and Evotomus.

Fig. 3.—The British pine marten in full winter coat. From "Shetland Pirates and other Wild Life Studies."

Besides the experience gained through long hours of vigil in a hiding-tent, Miss Pitt has made still more intimate acquaintance with many wild animals, not as mere pets, but as free companions and messmates. Of these, the most intellectual were a pair of ravens, which spent much of their time "ragging" the cook alternately with her cat; the most docile was a merlin hawk, the most playful a pine marten (Fig. 3), which came as a "kitten" from the Cumberland Fells, and quite the most foolish and awkward was a brown hare. There is much entertainment, as well as sound information, in both these volumes.

Herbert Maxwell.

Earth and Sun.

Earth and Sun: an Hypothesis of Weather and Sunspots. By Ellsworth Huntington. With a Chapter by H. Helm Clayton. Pp. xxv+296. (New Haven: Yale University Press; London: Oxford University Press, 1923.) 23*s.* net.

FOR half a century or more, it has been known that the earth's magnetic condition varies in striking similarity with the state of activity on the sun's surface. Many attempts have been made to establish similar connexions between meteorological phenomena and the sunspot cycle, but only within recent years has it been possible to record indisputable success in such attempts. The element most clearly affected is, as might have been expected, the temperature. Köppen's work, supported by that of several other writers, demonstrates that at sunspot maximum the mean temperature of the atmosphere is slightly *less* than at sunspot minimum. The difference is small, being 0°·6 C. in the tropics, and falling to 0°·4 C. in temperate latitudes. It seems not unlikely that the diminution at sunspot maximum corresponds rather to increased terrestrial absorption—due to a greater amount of ozone in the upper atmosphere — than to diminished output of radiation from the sun. The sun sends out increased corpuscular emission, and almost certainly increased ultra-violet radiation, at times of sunspot maximum, so that it would be rather surprising were its total radiation to be diminished at such times. On the other hand, intensified short-wave radiation would probably produce more ozone, which would intercept a larger proportion of radiation on its way to the earth's surface.

Small as is this temperature variation, it may be expected to produce important effects upon other terrestrial phenomena. Such effects would show a connexion with the sunspot cycle, possibly almost as close as that shown by the temperature variation itself. Hence the fact that a meteorological phenomenon is strongly correlated with the solar activity does not necessarily imply that the connexion is direct and independent. It is doubtful whether any other independent solar meteorological effect has yet been established, though some remarkable secondary effects are known. For example, Mr. C. E. P. Brooks

has shown that the great African lakes, Victoria and Albert, show variations of level amounting to several feet, practically in synchronism with the sunspot curve, the maxima of the two curves occurring together. The rainfall in the drainage basins does not show a corresponding variation, and it seems probable that the high level at sunspot maximum is due to decreased evaporation owing to the lower air temperature. Again, Douglass has found several cases in which the growth of trees, as indicated by the thickness of their annual rings, has varied nearly in synchronism with the solar cycle; this is clearly an index of some more immediate solar meteorological effect, whether of thermal origin or not.

The question as to a possible influence of solar activity on the barometric pressure is one which has received considerable attention. In the case of this element the solar effects must necessarily be more complicated than in the case of temperature, where the variations are likely to be everywhere of the same sign at a given time, though with local differences of magnitude. The total atmospheric pressure upon the earth can scarcely be appreciably affected by the sun's changes, so that if the solar influence increases the pressure in one region, there must be a countervailing change in other regions. The difficulty of detecting such effects is clearly much greater than that of demonstrating the temperature changes—itself an exacting task. Any such barometric changes which occur appear to be small, and must be obtained by averaging the results from a number of stations; if these happen to be distributed across the borders of oppositely-affected regions, the effect sought for may almost or quite cancel out; in any case it requires extremely detailed research to establish changes of particular sign in different regions, and to ascertain the limits of these regions.

Such investigations have of late years been prosecuted vigorously, and not without valuable results, by a number of American meteorologists—amongst others—and are recorded by Mr. Ellsworth Huntington in his new book. The sub-title of this work is "An hypothesis of weather and sunspots"; it is a companion volume to his recent book on "Climatic Changes," which dealt mainly with past relationships between the earth and sun, while the present work is concerned with existing connexions. The leading idea of both books is that terrestrial meteorology depends partly on purely terrestrial conditions, and partly on changes in the solar activity; the latter "are supposed to act chiefly through variations in barometric pressure and especially in the number, location, and intensity of cyclonic storms." It is also claimed that there is an important solar-activity effect on atmospheric electricity. The elucidation of such questions as these is obviously a matter of great interest and significance, and it is very convenient to have a summary of the present state of knowledge of the subject set out as is done in this book. The author has himself devoted enormous labour to this kind of investigation, and writes both with enthusiasm and with a wide acquaintance with the literature concerned. But to the reviewer it seems that much more evidence is required before it is safe to accept many of the conclusions which the author regards as established. In particular, the evidence for any regular effect of solar activity on barometric pressure and atmospheric electricity seems inadequate. There seems, however, to be a case for a connexion between sunspots and cyclones in certain tropical regions.

A considerable section of Mr. Huntington's book is devoted to the inverse problem of planetary influence upon solar activity. Mr. H. Helm Clayton contributes one of the four chapters in this section, and it is rather surprising to see in this chapter what seems to be an error elsewhere expressly pointed out by Mr. Huntington, namely, that the tidal influence of the planets on the sun is inversely proportional to the square of the distance of the planet from the sun. Many attempts have been made to relate the sunspot variations to planetary periods, but with doubtful success. The period of Jupiter (11·86 years) is not very different from the mean sunspot period (11·2 years), but the discrepancy is sufficient to render it very problematical whether any relationship between the two can be credited, even when allowance is made for the disturbing influence of the other planets. Mr. Huntington puts forward a hypothesis of electrical influence by the planets upon the solar atmosphere, but at present this is almost purely speculative. Such questions may be easier to decide when the nature of sunspots is better understood than now. At the moment it is at least a possible view that the main sunspot variation is due to some intrinsic solar period. S. C.

Biology and Sociology.

Essays of a Biologist. By Julian Huxley. Pp. xv + 306. (London: Chatto and Windus, 1923.) 7*s.* 6*d.* net.

THIS brilliant book, though somewhat disfigured by overlapping and repetition in certain parts, is one of the most suggestive and enlightening works for the popularisation of science which have appeared for a long time. It covers a wide field, and Mr. Huxley shows himself in it a man of wide interests, many parts, and an easy and attractive style of writing. He has two serious articles, covering much the same ground, on a new rationalistic conception of God; a sound

and careful survey of the relations of biology and sociology; a charming essay, full of careful observation, on the manifestation of emotion in birds; a light satirical discourse called "Philosophic Ants" on the relativity of our conceptions, two admirable discussions on sex psychology and on the biological approach to progress, and last, but not least, seven sonnets introductory to each chapter. They are quite good sonnets too.

It would be impossible in a short review to give any idea of the varied contents, and it would spoil the reader's enjoyment to pick out the plums too freely. But one may indicate the author's attitude on the more important topics of which he treats. The last two papers contain his attempted rationalistic reconstruction of the idea of God, being an analysis and elaboration of the statement that "the conception of God always represents man's idea of the powers operating in the universe." It will be noticed that the second of these papers, delivered at Woodbrooke at the sixth of the Unity History Schools, approaches more nearly, on the side of divine personality and of communal religion, to the ordinary attitude of the Churches.

It is not to be supposed that Mr. Huxley weakens anywhere in his allegiance to positive science. He tells us in the first paper that a "law of Nature is not something revealed as absolute, not something imposed on phenomena from without or from above; it is no more and no less than a summing-up, in generalised form, of our own observations of phenomena." He adopts, in fact, entirely in this matter the position which Dr. E. W. Hobson has been illustrating so fully in his recent Gifford Lectures. Students of Comte will note with interest that "the sciences are a hierarchy, the subject-matter of one constituting the foundation for the next in the series." The relation of biology to sociology is elaborated more than once in the book as an illustration of this. Sociology subsumes all the conclusions of the lower or earlier sciences, and adds to them various new considerations, or laws, of its own. With man in fact there has been a "radical change in evolutionary method" due to his power of transmitting the results of abstract reasoning by collective tradition.

Many readers will find the chapter on "Bird-Mind"—"Ils n'ont que de l'âme"—the most delightful thing in the book. The account of the egrets' honeymoon in Louisiana is almost too good to be true. Apparently they sit side by side for hours together with their long necks intertwined in a true-lovers' knot.

Mr. Huxley is right, after all, in giving the first place in the book to the essay on progress, which puts the doctrine so usefully and convincingly from the point of view of the biologist. It was certainly a serious omission, as he points out, to have had no chapter on this aspect of the subject in "Progress and History." We can see the human facts so much more clearly as they arise from the common biological evolution of universal life. From this point of view progress is seen to consist in "an increase in the control exerted by organisms over their environment, and in their independence with regard to it"; in an increase in the harmony of the parts of organisms; in an increase in the psychical powers of willing, of feeling, and of knowing. In short, progress is the growth, in power and harmony, of the soul; and man, being the crown of animate existence, embodies the principles of progress most completely.

F. S. MARVIN.

The Petroleum Industry.

A Handbook of the Petroleum Industry. By Dr. D. T. Day, Editor-in-Chief. In 2 vols. Vol. 1. Pp. x+964. Vol. 2. Pp. vi+1006. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 2 vols. 3*l*. 15*s*. net.

THIS work, which might aptly be termed the "Redwood" of American petroleum literature, has been written with a very definite purpose in view, namely, as an aid to the best utilisation of oil and the development of new resources to offset the impending shortage of supply in the United States. In a striking preface the editor-in-chief, Dr. Day, discusses dispassionately the truth of a situation which many people, both in Great Britain and in America, seek to gloss over, usually from self-interested motives. Briefly the situation is this: there exist less than twenty years' resources of petroleum in the United States at the present rate of supply and demand. To this we may add that one-fifth of the total oil requirements of that country latterly has been derived from Mexico; but in Mexico also there has been a startling decline in output noticeable recently, due principally to salt-water encroachment in some of the most productive wells. Small wonder, then, that serious-minded Americans (and Europeans too, for that matter) are apprehensive of the future, and that the several specialists responsible for this handbook are actuated by a common motive, that of contributing "their special knowledge to this volume, in the hope that more oil may be found and better utilisation be given it."

Written expressly for the public, the work makes a more direct appeal to the engineers who produce and refine oil, and it may be said at once that the sections concerned with these aspects of the industry are by far the best. From the point of view of the general public, the enormity of detail, the size of the work (nearly 2000 pages of comparatively small type), and the impression

it conveys at first glance of being a highly technical treatise, will probably prove rather overwhelming, though it is to be hoped that these factors will not be detrimental to a wide circulation and thus defeat the main objects of its production.

The work is much more than a mere compilation. Fifteen specialists in different branches of the industry have contributed to its undertaking, and as a standard book of reference it thus stands alone. No one man, be he a Heaven-sent genius, can comprehend adequately the intricate ramifications of the oil-industry of to-day; no written work, the product of a single human brain, can possibly do justice to a subject the rapid evolution of which depends on progress along so many highly specialised branches of natural science.

Yet, like all things material, there are obvious disadvantages in the co-ordinated essays forming the substance of this work. Not the least of these is the strong American bias noted throughout; also the apparent lack of appreciation of problems which beset others than those engaged in the American petroleum industry. After all, though we readily admit United States supremacy if measured in terms of annual oil production, the Old World may surely claim a modest share in the research and invention which have contributed to the wonderful progress of petroleum technology within the last half-century. American industrial problems are not necessarily Eurasian, nor are American solutions to those problems necessarily final to foreign operators. Hence without for one moment casting any reflections on the high merit of the work, it seems to us that a far wider purpose (thus a correspondingly greater value) would have been served had the book been planned on a more broad-minded, international basis, with something more than passing mention of oil affairs external to the United States.

This international element, had it existed, would have balanced the detailed description of the stratigraphy, structures and oil occurrences of North America with something more than a few cursory paragraphs of similar Eurasian criteria, as given by Mr. F. G. Clapp, responsible for the first section on "The Occurrence of Petroleum." Mr. F. H. Lahee, in the second section on "Field Methods in Petroleum Geology," would have been compelled to demand (with great advantage to the section) more space to deal with methods applicable to other than simple phases of geological surveying. Mr. R. G. Smith would likewise have included some description of the impregnated sediments well-known in European industries in his section on "Asphalt," while Mr. D. E. Day's section on "Oil Shale" would have profited by some account of European occurrences and methods. Perhaps these, and similar omissions, will be remedied in future editions of the work; at all events most of the other sections are so good that it would be a pity if this were not done, thus making Day's "Petroleum Industry" a standard work in every sense of the word.

H. B. MILNER.

Our Bookshelf.

Friction. By Dr. T. E. Stanton. Pp. xiv+183. (London: Longmans, Green and Co., Ltd., 1923.) 12*s.* 6*d.* net.

IN recent years considerable advances have been made in our knowledge of lubrication, static friction, and the resistance exerted by fluids on bodies moving through them. The importance which this knowledge has for engineers can scarcely be overestimated, and it is fortunate that the man who has had the greatest share in making these advances has been able to find time to write a complete account of the whole subject.

In the term "friction," Dr. Stanton includes all the agencies by which the moving parts of a machine are retarded and their energy dissipated. First of these in importance comes fluid resistance, and the first chapter is devoted to viscosity, the physical property on which all fluid friction depends. The second chapter, on the "External Friction of Fluids," opens with an account of the application of Newton's principle of dynamical similarity to fluid friction, and the results of a wide range of experiments on the flow of fluids through pipes are discussed from this point of view. The remarkably wide scope of the discussion of the surface friction of fluids may be judged from the fact that the friction may be estimated from experiments on the flow of liquids or gases in pipes, from direct experiments, with sheets of metal exposed edgewise in the wind, from meteorological observations, from tidal data, and from observations of the velocity of the wind close to the surface of a flat plate. All these methods lead to nearly identical results.

Chapter iii. is devoted to the hydrodynamical theory of lubrication; recent work is summarised, and an interesting account is given of the mathematical considerations which led to the discovery of Mitchell's method of lubricating the thrust blocks of a steamer's propeller shaft.

It is perhaps to be regretted that the description of Hardy and Doubleday's recent researches on boundary lubrication has been compressed into one paragraph. The application of this work to engineering has not yet gone very far, but it seems probable that developments in that direction may be expected in the near future. The remaining chapters, on "Rolling Friction" and on "Friction and Heat Transmission," introduce problems about which little is known, but perhaps for that very reason they are as stimulating as any in the book.

The engineer will find useful information in every chapter, but it is to the physicist that the book makes its strongest appeal. It would be difficult to pick out from the whole range of physics a better example than the subject of friction affords of the interdependence of mathematical and experimental methods. The logical way in which the matter is arranged serves to emphasise this point of view.

G. I. T.

Real Mathematics: Intended Mainly for Practical Engineers, as an Aid to the Study and Comprehension of Mathematics. By E. G. Beck. (Oxford Technical Publications.) Pp. ix+306. (London: Henry Frowde and Hodder and Stoughton, 1922.) 15*s.* net.

ARE engineers as bad as they pretend to be, or, at any rate, as Mr. Beck wishes us to believe? His desire is "to bring about a change of attitude towards mathematics," "to show the thing as an actual, tangible reality, instead of as a collection of rigid and unrelated rules and formulæ." He asserts that "the physical realities of mathematics have become swathed about with wrappings of mystery and suggestions of the supernatural." No doubt there is still room for improvement in mathematical text-books; but Mr. Beck must be singularly ignorant of modern text-books if he imagines that these sentences are anything but a libel on them.

In any case, if modern mathematical text-books are at fault, their improvement will not be secured by Mr. Beck's methods. At bottom there seems to be nothing in his explanations that is not contained in most of the decent school books—only Mr. Beck talks a lot. In addition he says some absurd things. The most striking example is perhaps the discovery that $\sqrt{-25}=-5$.

Mr. Beck's views on mathematical teaching are best understood from the following self-revelation: "The ability to solve a differential equation is, of itself, not worth five seconds of effort to acquire; but if such ability enable a man to design machines or structures more economically, or if it serve him as a key to the recorded experience of others, its value would clearly be so enormous as to lie beyond the scope of ordinary means for estimation." In other words, the only justification of mathematics is the creation of dividends!

The Social and Political Ideas of some Great Mediæval Thinkers: a Series of Lectures delivered at King's College, University of London. Edited by Prof. F. J. C. Hearnshaw. Pp. 223. (London, Calcutta and Sydney: G. G. Harrap and Co., Ltd., 1923.) 12*s.* 6*d.* net.

THIS volume contains eight studies of political thought in the Middle Ages which, with two exceptions, appear substantially in the form in which they were delivered as a course of public lectures in King's College, London, during the autumn of 1922. Seven of the lectures deal with individual thinkers, beginning with "Saint Augustine and the City of God," a composite production by the Rev. A. J. Carlyle and the editor, and one of the exceptions mentioned above, and ending with "John Wycliffe and Divine Dominion," also by the editor. It will be noted the term "Middle Ages" is, chronologically, if not theoretically, liberally interpreted. The remaining lectures deal with John of Salisbury (E. F. Jacob), St. Thomas Aquinas (Rev. F. Aveling), Dante (E. Sharwood Smith), Pierre Du Bois (Eileen E. Power), and Marsilio of Padua (J. W. Allen). The Principal of King's College contributes the introductory lecture, in which he draws an illuminating distinction between political theory and political thought, and fully justifies the claim for the interest of the subject to the modern reader who is not specially concerned with medievalism as a whole. The lectures cover the development of the idea of a national state out of the theory of an international organisation, spiritual or temporal, and are therefore not without bearing upon political theory of the present day.

Hunters of the Great North. By Vilhjalmur Stefansson. Pp. 288+16 plates+2 maps. (London, Calcutta and Sydney: G. G. Harrap and Co., Ltd., 1923.) 7*s.* 6*d.* net.

IN this volume Mr. Stefansson recounts some of his early experiences in the Arctic when he was a member of the Leffingwell expedition in 1906–7. He tells of his travels with the Eskimo, how they taught him to hunt, to accept their diet and mode of life, to build snow houses and generally to live in comfort in a region which people will persist in regarding as inhospitable in the extreme. It is a volume of the lore of the Arctic full of vivid descriptions and personal incidents. The chapters on hunting contain a great deal of the natural history of the caribou, polar bear and seal, and there is of course much of interest regarding the Eskimo. Mr. Stefansson has given us no book of polar travel of greater interest than this volume. It should help to dispel some of the current fallacies regarding the Arctic climate and conditions of life in the far north. The call of the north is in its pages, which will awaken memories among those who know the ice, and stir others with a longing to go and see. R. N. R. B.

Mirrors, Prisms, and Lenses: a Text-book of Geometrical Optics. By Prof. James P. C. Southall. Enlarged and revised edition. Pp. xx+657. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1923.)

THE revised edition of Prof. Southall's text-book of geometrical optics, in addition to a number of new problems scattered throughout the book, contains an important new chapter at the end of the volume. The historical notes dealing with the rectilinear propagation of light, and optics in the seventeenth century are of considerable interest. It is usually stated that Newton was the first to distinguish seven colours in the prismatic spectrum, but Maurolycus (1575) in the explanation which he gave of the circular arc of the rainbow directs attention to the four principal colours, together with three other colours which he regarded as transitions. Reflection prisms are discussed at some length, and new and approved schemes of optical calculation, partly due to Mr. T. Smith, are described. A word of praise must be given to the diagrams.

Introduction to Practical Mathematics. By V. Seymour Bryant. Pp. 95. (Oxford: Clarendon Press; London: Oxford University Press, 1923.) 2*s.* 6*d.* net.

MR. BRYANT'S little book is intended to supply the needs of classes preparing pupils for the entrance scholarship examinations in science in Public Schools, and is based upon a syllabus issued by the Science Masters' Association at the request of the Joint Standing Committee of the Head Masters' Conference. The course suggested in the book is very suitable and interesting, and the explanations offered should prove of value to the pupils. S. B.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Relation between Solar Activity and Atmospheric Electricity.

DR. CHREE in his reply (NATURE, September 8, p. 361) to my communication on solar activity and atmospheric electricity (NATURE, August 11, p. 203) first makes reference to the status of the question as to the effect of sun-spot activity on the secular change of the earth's magnetism. Those who have investigated this question have reached apparently contrary conclusions according to the phenomenon examined, the data used, and the method employed by the individual investigator. It would require too much space to enter into detail as to the reasons for the discordant results. Let it suffice here to state that Dr. Chree and I have investigated different phenomena. Thus Dr. Chree, on the basis of the Kew data alone, concluded, contrary to Leyst, that the secular change of the *magnetic declination* did not vary markedly, if at all, with sun-spottedness.

Such a restricted investigation could, of course, not be accepted as settling the broad question as to whether any appreciable change in the *direction of magnetisation* of the earth may be related to solar activity changes during a sun-spot cycle. I, on the other hand, confined my investigation solely to the question whether there was an appreciable change in the earth's *intensity of magnetisation* which might be associated with change in solar activity during the sun-spot cycle. Instead of relying upon the data from one station alone, I used the intensity data from eight stations distributed around the globe, namely: Kew, Potsdam, Pola, Bombay (Colaba and Alibag), Honolulu, Sitka, Cheltenham (Maryland), and Porto Rico. Regarding the various questions which must be considered in investigations of this character, the interested reader may be referred to my paper on the subject,[1] at the conclusion of which the intention was stated of making a still more comprehensive examination, as soon as additional data were available.

With regard to the difference in the method or formula used by Dr. Chree and myself when investigating a possible relationship between solar activity and atmospheric electricity, let me state briefly the assumptions involved. Dr. Chree in his paper[2] adopts a formula which assumes that there is strict synchronism between the phenomena of sun-spottedness and atmospheric electricity, and that for the same sun-spot number, during the first and second halves of the cycle, for example, the atmospheric-electric element investigated should have precisely the same value. In my formula (NATURE, August 11, p. 203) I introduced a term, provisionally called a time- or cycle-term, which was intended to take into account, approximately, a possible a-cyclic effect in atmospheric electricity during a sun-spot cycle such that the atmospheric-electric element considered, barring other disturbing causes, would not have precisely the same value for the same sun-spottedness. With the aid of this additional assumption, which does not appear unreasonable in view of similar effects in other geophysical and cosmical phenomena, an improved mathematical representation was obtained and higher values of the correlation coefficient were derived than those which Dr. Chree had found. No futile attempt was made to get an *exact* representation by unduly multiplying the number of unknowns to be determined by the method of least squares. The desire was merely to obtain, in accordance with the best practice, a sufficiently satisfactory representation of the observed facts with the *fewest* possible unknowns; the general concordance in the derived unknowns from widely separated stations would appear to be ample justification of the formula employed.

It must be realised that no method of applying an a-cyclic correction, due to an undiscovered cause, can be made perfect; however, when more extensive data for several sun-spot cycles are available, no doubt improvements may be made. In this connexion it may be remarked that Dr. Chree's method of applying a-cyclic corrections to the observed magnetic and electric diurnal variations has not yet been generally adopted. However, no great refinement in mathematical method is requisite to show, even for the data at present available, that a definite relationship between solar activity and atmospheric electricity is sufficiently plausible to merit careful attention. Some of the evidences have already been cited in my previous communication and reference has been made to a later and more complete paper.[3]

Dr. Chree directs attention to some low values of the atmospheric potential-gradient at the Ebro Observatory; by reference to the observatory bulletins it will be found that recent low values, especially during the period June-October 1922, were not unnoticed by the Observatory, and that possible artificial disturbing causes were investigated, as the result of which some changes have been made. The Observatory will doubtless make such additional tests and redetermination of reduction factor as may be requisite in the circumstances. This later information from the Ebro Observatory had not been received at the time of my previous communication, in which data only to 1921 inclusive were utilised. (The date for No. 11 in Table 2 of my previous communication should be 1921·5, instead of 1921·1.)

I am glad that Dr. Chree is helping to keep alive an interest in the highly important question as to possible variations in atmospheric electricity which may have to be associated with changes in solar activity. We may rest assured that until this question is definitely settled no complete theory of the origin and maintenance of the earth's electric charge can be definitely formulated. My main purpose appears to have been accomplished, namely, to bring back into the literature a question for reinvestigation which was actively discussed more than a half-century ago and then dropped for want of sufficiently accurate data of the requisite extent. It is hoped that the renewed discussion will contribute towards the multiplication of atmospheric-electric stations where every possible care will be taken to ensure continuity of strictly comparable data for as long a period as possible. Among other precautionary measures, more frequent and more extensive controls, than is at times the case, of the factor for reducing observed potential-gradients to an infinite plane, are requisite.

Long-range Particles from Radium-active Deposit.

IN a letter to NATURE of September 22, p. 435, under this heading, L. F. Bates and J. Stanley Rogers suggest that the H-particles found by us (NATURE, September 15, p. 394) to become expelled from the atoms of Be, Mg, and Si, probably also of Li, by α-particles, are really identical with the long-range α-particles which these authors have obtained from radium C deposited on a brass disc. Highly interesting as their communication is, it does not, however, seem to have any direct bearing on our results.

The difference in brightness between the scintillations from α-particles and from H-particles viewed under identical conditions is so conspicuous, that no mistake is possible. Comparing the former to stars of the first magnitude, the latter would be of about the third magnitude; that is, a ratio in luminosity of about 6 to 1. By way of emphasising this difference we have, in the same scintilloscope, demonstrated the scintillations due to the H-particles from aluminium foil inside a glass capillary charged with emanation, together with the scintillations from polonium α-particles, before the physical section of Skandinaviska Naturforskaremötet, held in Gothenburg this summer. With due precautions the same experiment can also be carried out with a thin-walled silica capillary containing a few millicuries of emanation, so as to demonstrate the H-particles from silicon. Although there is very little doubt that the scintillations we have observed are really due to H-particles, an *experimentum crucis* can, of course, be made only by measuring their magnetic and electric deflection.

As was stated in our first communication, our final experiments were carried out with a minute emanation vessel divided into several communicating compartments of equal length, in which thin layers of different substances were spread over the bottom, made from thinnest copper foil. Control countings of the particles expelled from the naked copper foil of an empty compartment proved the number of these to be only a fraction of those expelled from the compartments charged with other substances. As the absorption curve for the "copper"-particles agreed with a theoretical absorption curve calculated for natural H-particles from hydrogen supposed to be occluded in the copper, there seems to be no reason for assuming them to be expelled directly from disintegrating atoms of radium C. But even if that were granted, there is no reason for ascribing that origin to the much more numerous particles of relatively short range expelled from the Be, Mg, and Si compartments of the same vessel, considering that the amount of emanation and its products present within each compartment was practically the same.

As a matter of fact a small number of scintillations of α-type was generally observed in our experiments, beside the much fainter H-scintillations, especially at the lowest values of absorption, when they were relatively numerous. We have so far not had occasion to examine these particles or their origin but have for the time being assumed them to be identical with the particles found by Sir Ernest Rutherford to be expelled from oxygen (*Phil. Mag.* vol. xxxvii. p. 562) which have in succession been taken for oxygen atoms carrying a single charge, double charged X nuclei, and now, apparently, α-particles of abnormally long range.

In conclusion, we may say that, judging from the experimental data at present available to us, we cannot see any other way of explaining the origin of the particles we have observed than by upholding our former view, namely that they are H-particles expelled at an artificial disintegration of the beryllium-, the magnesium-, and the silicum- (probably also the lithium-) atoms and not any long-range particles from radium-active deposit as the title given by the Editor to our first letter would seem to suggest. In that letter, in addition to the corrections pointed out in NATURE of October 13, p. 540, the word "neutral" should have been printed "natural."

Colour Vision and Colour Vision Theories.

WHETHER Prof. Peddie's explanations are adequate is a matter for the reader to decide. Let us take one of a fact which is conclusive evidence against the trichromatic theory. If the terminal portion of the red end of the spectrum be isolated in my spectrometer it will appear as a faint red upon a black background. If the eye be fatigued with red light, even by looking through a red glass held against a light for one second, the red will not be visible for some considerable time, but the eye may be fatigued for twenty minutes with yellow light without interfering with the visibility of the red light.

Prof. Peddie's explanation is as follows: "That there is no shortening at the red end of the spectrum after fatigue with yellow light follows at once if both the red and the green sensations are fatigued by the yellow light, while all three sensations, red, green, and blue, are present to some extent at all visible wave-lengths." But this explanation, which is inconsistent with the work of König, Abney, and others, does not explain why there is considerable shortening after slight fatigue with the red glass. Prof. Peddie does not explain Shelford Bidwell's crucial experiment, namely, that his red borders are not seen with spectral yellow light but are seen with a mixed yellow made up of red and green matching it.

As with other departments of science, the minutest accuracy is required in experiments on colour vision. Many results are due to impure colours and stray light. A chemist would not do Marsh's test for arsenic when he had bought his zinc at an ironmonger's and his sulphuric acid at an oil shop, both being contaminated with arsenic, but many workers are satisfied to use coloured papers for work on colour vision.

If the positive after-image of a spectrum be viewed it will be seen to disappear from the red to the violet end, and on the trichromatic theory it is stated that the positive effect of the red sensation disappears before that of the green; but in an absolutely dark room, if pure spectral yellow light be thrown on a white screen and a flicker apparatus rotated slowly in front of it, the yellow will not change its hue; on the trichromatic theory it should become green. The results are quite different when stray light is allowed to fall on the screen as well.

London, October 27.

Sex Chromosomes in Plants.

I HAVE recently been investigating the cytology of a number of diœcious plants with the intention, if possible, of throwing light on the matter of sex chromosomes in plants. Incidentally, I took up the genus Lychnis, one species of which, *Melandryum rubrum*, Garcke (*L. dioica*, L.), has been examined previously by Strasburger. In detailing his observations he states that, in both sexes, there are twelve pairs

of chromosomes present in the somatic cells. In the heterotype division he found one pair of bivalents much larger than the others, but the individual members of this pair were of equal size; thus no signs of the disparity indicating the possibility of two types of microspore were revealed.

I have examined its close ally, *Lychnis alba*, Mill., and find similarly twenty-four somatic chromosomes, of which two are larger than the rest. In the female plant at the reduction division these two appear similar; thus the daughter nuclei are alike. In the male, however, the two large chromosomes differ from one another both in size and shape; the larger one is bent, somewhat in the shape of a hockey stick, with the curved end pointing outwards from the spindle, whilst the smaller somewhat pear-shaped one is not more than two-thirds its size (Fig. 1). The shape is quite constant and the appearance is the more striking in that this pair of chromosomes takes the stain much more strongly than the others.

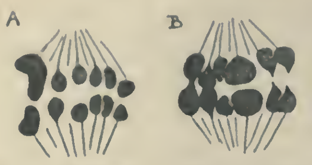

FIG. 1.—Heterotype division in *Lychnis alba*, Mill. A: male; B: female.

Since *L. alba* is so closely related to *L. dioica*, in which Shull has demonstrated sex-linked characters with the male heterozygous for sex, it seems more than probable that we have here a definite case of an XY pair of chromosomes in the male with a corresponding XX in the female. This is the first definite record of sex chromosomes in a Dicotyledon.

A full account of this and other species of Lychnis and their hybrids will be published shortly.

Powers of Perception of Birds.

MY attention has been directed to a note in NATURE of November 18, 1922 (vol. 110, p. 677), containing references to an article on "The Sense of Smell in Birds" (NATURE, June 17, 1922, p. 783), and to Dr. H. H. Beck's paper on "The Occult Senses in Birds" (*Auk*, 1920, xxxvii. 55). As your note intimates, there is evidence that neither by "occult sense" nor by smell do turkey vultures find their food. They certainly depend largely upon a very keen sense of sight, as is shown by the following incident.

A toy rabbit consisting of white plush and excelsior packing was given to our little girl a number of years ago. It proved to be a favourite toy. One night she forgot it and left it lying in the yard. As we sat at breakfast the next morning we were greatly surprised to see a turkey vulture strutting in a circle about the toy rabbit as it lay on the ground, and eyeing it with head turned to one side. Here was something new to his experience. It was certainly the form, but not the substance of a dead rabbit. If the turkey vulture has an "occult sense," in this case at least he did not depend upon it, or, doing so, was completely deceived.

The position of the writer of the note in NATURE is one to which we can subscribe when he says: "It is surely more reasonable to attribute these [powers of perception] to greater acuteness of the known senses than to imagine new senses for which no physiological basis can be suggested."

Population and Unemployment.

IN the résumé in NATURE of October 13 of the presidential address by Sir William Beveridge to the Economics Section of the British Association, the point which raised so much discussion in Liverpool is indicated by this sentence:—"Increased birth control is not required by anything in the condition of Europe before the War, and is irrelevant to our present troubles." As this idea has already been hailed by many, may I point out that Sir William entirely ignored the *unemployables*. Those who are unemployable through organic disease, feeble-mindedness, general debility, and various other characteristics of a "C 3" and physiologically inferior population do not appear in the ordinary list of unemployed, but they are, nevertheless, a huge financial burden on the community. Both a financial strain and a physiological danger to the race, they not only breed and reproduce their like if left without birth control; but they are brought into existence in otherwise healthy stocks whenever mothers under hard conditions reproduce too rapidly. Only by means of constructive birth control can women space their children so as to ensure the likelihood of reasonable health to those they bear under the modern and unnaturally hard conditions of slum life.

While Sir William Beveridge may play at ninepins with the primitive "Malthusian theory," it is most dangerous that, misled by his phrases, uncritical persons who confuse Malthusianism with constructive physiological birth control should be given such inopportune encouragement. Statistics confirm our common-sense observation that intelligent members of the better stocks are widely using birth control; hence, unless we do have an increase of birth control so that the inferior stocks also use it, we shall continue racially to deteriorate at an ever-accelerating speed.

MARIE C. STOPES,
President of the Society for Constructive Birth Control and Racial Progress.

A Possible Cure for Cancer.

WHILST reading Prof. Johnstone's remarks (Lancs. Sea-Fish. Lab. Report for 1922 (1923), p. 19) on malignant (cancerous) growths in fishes, I was struck by and seized upon the statement that "wen" is an example of a controlled growth.

So long ago as 1908 I remember Prof. Farmer suggesting in his lectures on "The Cell" that "cancer" might be due to lack of control of the individual as a whole over certain tissues, and this view has gained force ever since that time; but now arrives a statement that "wen" is a controlled growth. Let it be assumed that both statements are correct; then the individual with a wen contains or has contained in its system somewhere a controlling influence which—from many analogies—may not improbably exist in the blood. Now if wens occur in other suitable animals than man it would be an easy matter to extract plasma or other components of the blood for injection into other individuals of the same species having uncontrolled (cancerous) growths in order to test whether the controlling influence exists there and can be passed on to another individual.

If the suspicion were confirmed, a cure for cancer would be obtained, as the application of a similar process to man would no doubt follow very swiftly.

Or again, assuming that individuals with wens have an obvious control of a tendency to cancerous

growths, the suggestion is provoked that all normal mature individuals contain a factor—probably biochemical—which controls a tendency to abnormal growth. Why not then try simply the injection of blood-plasma or other constituents of the blood from normal mature individuals into cancerous subjects ?

It is of course possible that the factor inhibiting abnormal growth may lie dormant in the healthy individual or only occur at a particular phase of life—one of which may be at about the end of the growth period—and may not therefore be transmissible in blood constituents at all stages of the mature life-history, even supposing that the blood is the locus of the factor when it is active. A further possibility may be that only certain apparently normal individuals possess constantly an *active* growth-restricting factor and that these individuals remain to be identified. Whatever the importance of the above surmises may be, it would seem clear that the economy of individuals with "wens" must be regarded at present as of great importance in the study of cancerous growths. It is realised that there is a great deal of speculation in the remarks made above, but the importance of the subject is regarded as sufficient excuse.

Science and the State.

LORD SALISBURY has noticed with great pleasure your appreciative article (October 27, p. 609) on the co-operation of the different parts of the Empire in scientific research dealt with in his recent speech to the Imperial Economic Conference. He would like, however, to assure you and your readers that when he spoke of the willingness of scientific men to place their services at the disposal of the Government and the community for "far less than the true remuneration of their great talents," he was referring not to the scientific staff of the Department, but to the distinguished men who serve on the Advisory Council and other Committees and Boards of the Department, most of them entirely gratuitously. The members of the Advisory Council are offered a modest honorarium, but it is not always accepted.

PHILIP FARRER,
Private Secretary.

Privy Council Office, Whitehall,
October 30.

A Representative Scientific Council.

THE proposal made in the leading article in NATURE of October 13, page 529, seems of the utmost importance, and is therefore likely to be discussed by abler pens than mine. I venture, however, to touch on some considerations not yet covered by your opening statement.

In a world of disillusion, with Church and State both in discredit if not in disgrace, there is a widespread and keenly felt need for wiser guidance. Here is the opportunity. Some of us would say that in an age of revolutions, it is not a further enforcement of authority by the method of violence that is needed. To substitute the dictature of "Science" for the dictature of the proletariat is only to demonstrate that the real enemy is the bourgeois and the bureaucrat. Here is our temptation.

We have no recognised definition of scientific "truth" as distinct say from war truth, newspaper truth, or Quaker truth. Do we mean that our conclusions are always "contradictoire," open to challenge, verification, or correction ? If so, there is obviously no case for enforcing them on an ignorant but reluctant populace.

There is already some distrust of the learning of the medical profession. They are wise enough to be content to advise their patients, but not to enforce their advice. The Ministry of Agriculture is wise enough to issue advice. From the Board of Education we should welcome rather more advice and rather less administration. Just consider how much mischief might be done in the present state of our knowledge of eugenics by a new tyranny of good intentions and ignorance.

On the other hand, there is a very strong case for some public body of scientific experts which might advise and report on all matters affecting the public welfare ; for example, on the children of Russia, the reafforestation of Greece, the rebuilding of Tokyo, the finances of Germany, the frontiers of France. If some scientific (not political) body meeting in Geneva could find the right answers to these questions, some of us would be content to sacrifice all other sorts of authority vested in the League of Nations in favour of the authority that might ultimately accrue to an oracle which confined itself to good advice.

For the word "democracy" we might substitute "scientific initiative and democratic veto." We need both. Almost all that can be done by mass movements, like trades unions and armies, is to veto, to stop other things being done by other people. Initiative, doing new things, is generally the work of individuals, not of mobs. The case for a scientific advisory body is far stronger than any existing political system recognises. The House of Lords may be earmarked for the future development of Trades Unionism, but the Privy Council is an existing institution which could be developed into an acting advisory council, with no authority to enforce its advice.

It may be difficult to draw the line of representation among the claims of metaphysics, theology, theosophy, anthroposophy, anthropology, psychical research, and experimental psychology. An excluded minority of Christian Scientists might be hostile, as you say. Hence the virtue of Prof. Oppenheim's maxim :—"There will be voting and the majority will indeed decide, but that decision will only bind that majority. In matters of 'scientific' opinion are we not justified in saying that no majority however great should seek to enforce its decisions on any minority no matter how small ? "

On the other hand, consider the immense power that might be wielded by an advisory organisation that merely advised its members to "withhold support" from an existing political institution which seemed to be going astray. Imagine, for example, that during some recent wars the General Medical Council had advised its members to refuse service in all ambulance units or a Chemical Society disowning members engaged in manufacturing explosives, or a Trades Union refusing to make munitions or to accept Treasury notes in payment !

There is a little difficulty about registration. Is a university degree in science enough, or is research work necessary ? Or might the standard be lowered to the Preliminary Scientific Examination ; and what about people of quite obviously exploring habits of mind who have never had the chance of a university education ? The analogy of the Teachers' Registration Council a little suggests that registration might be the only aim which would be achieved.

The great thing is to maintain an offer of the best scientific advice available for the widest possible community.

HUGH RICHARDSON.

Wheelbirks, Stocksfield-on-Tyne,
October 23.

Radio Direction Finding by Reception.

THERE are in use to-day three principal systems of direction finding by which the apparent direction of arrival of a train of electromagnetic waves can be observed and, under suitable conditions, the direction of a radio transmitting station determined. These are usually described as the Bellini-Tosi system, the single frame system, and the Robinson system. The Bellini-Tosi system has been very fully developed by the Marconi Company for use on land and on board ship as an aid to navigation, and is the system most usually employed in this country for that purpose. The coil frame system has received most attention in the United States, and has there been the subject of a great amount of research work. The Robinson system, for reasons which will appear later, is specially suitable for use in connexion with direction finding in the air and has mainly been developed with that end in view. All three systems have been for the most part the subject of independent development and their several merits have been the subject of considerable controversy.

In general, however, all the systems operate upon the principle that the magnitude of the electromotive force induced in a vertical loop or coil of wire by an electromagnetic wave depends upon the angle between the plane of the loop and the wave front of the arriving wave. An electromagnetic wave can be considered as consisting of electric and magnetic forces which are at right angles to each other and to the direction of travel of the wave. These two force vectors are in phase with each other and each varies rapidly in a periodic manner. The effect on a wire placed in the field due to such a wave can be deduced from consideration of the effect of either the electric or the magnetic fields in the wave front. In the case of a single coil vertical loop of wire it can be shown that the periodic magnetic field due to an electromagnetic wave the wave front of which is plane, though not necessarily vertical, introduces in the loop an alternating electromotive force the maximum value of which is given by the following expression:—

$$E_m = \omega H_m A \cos \alpha$$

where ω is the periodicity of the wave, H_m the maximum value of the horizontal component of the magnetic field in the wave front, A the area of the loop, and $90° - \alpha$ the angle between the plane of the loop and the horizontal component of the magnetic field. The effect of the vertical component of the magnetic field may be disregarded since the plane of the loop is vertical and therefore cannot be linked by this component. If the loop is rotated so that the electromotive force becomes zero the plane of the loop is then parallel to the horizontal component of the magnetic field, and the direction whence the waves are travelling is thus at right angles to the plane of the loop. The direction of arrival of the waves can therefore be determined with an ambiguity of 180°. It can be shown that, in general particulars, the underlying principles of all the three systems in use to-day are the same—and that the systems are in their action essentially equivalent to the single rotating loop.

The single coil system most closely approximates to the simple theoretical case. A tuning condenser is, however, usually introduced in series with the coil across which the amplifying and detecting apparatus is connected; but it can be shown that the potential difference across this condenser depends on the orientation of the frame in the same manner as the electromotive force induced in the frame. The single coil, as used in practice, consists, as a rule, of several turns of wire instead of a single turn. These turns are usually spaced in a series of equally dimensioned loops in nearly parallel planes (box type coil), or are wound spirally in the same plane (pancake type coil). In the case of a pancake coil the quantity A in the expression given above is replaced by the effective or mean area of the coil. In the case of box type coil, since the winding of the coil is, of necessity, slightly askew to the axis of the coil, there is the possibility of an effective turn of wire being introduced the plane of which is practically at right angles to the main turns of the coil; the effect due to such a turn, however, introduces an error not exceeding 0·1°, which is negligible for all ordinary purposes.

The connexion of the tuning condenser and receiving apparatus to the coil introduces certain disturbing effects. First the electromotive force picked up by the leads and the whole circuit, although small compared with the maximum value of the potential difference across the tuning condenser, may be sufficiently strong to give an audible signal when the coil is orientated so as to make this potential difference zero (*i.e.* $\cos \alpha = 0$). In this way an ill-defined minimum may be produced, and accurate determination of the bearing made more difficult. Secondly, a bad zero may be produced by what is known as "vertical" or "antenna" effect. One side of the tuning condenser is connected to the grid of the first receiving valve, while the other side is connected to the filaments of the valves, to which in turn are connected the filament and anode batteries. The capacity to earth of the two sides of the coil joined to the tuning condenser will, therefore, in general be unequal, and a potential difference will be produced across this condenser even when there is no circulating current in the coil. One result is a blurring of the minimum, and another is that the two minimum positions are found on rotating the coil not to be exactly 180° apart, owing to the fact that the superimposed potentials due to the antenna action of the coil are nondirectional. These effects can be eliminated, however, by the introduction of a small variable balancing condenser between the grid of the first valve and the tuning condenser.

In the Bellini-Tosi system two large rectangular or triangular loops each of a single turn are erected with their planes at right angles. To each of these a small field coil is connected in series. These small coils are again mounted with their planes at right angles and between them is pivoted a small search coil, attached to which is a pointer which moves across a horizontal circular scale divided into degrees from which the observed bearings are read off.

The two field coils reproduce in miniature the field in which the main coils are placed, and the search coil turning within the small field coils is equivalent to

a single rotating coil directly receiving the energy of the waves. Thus the Bellini-Tosi system is in theory exactly equivalent to the ideal single turn rotating loop. The system, as in case of the single frame coil, is liable to a certain amount of "antenna" effect. It is also necessary in erection for care to be taken that the similarity of the two loops and their circuits is ensured, and that the planes of the loops are accurately at right angles.

In the Robinson system two coils, which differ as regards their area-turns, are fixed rigidly at right angles and pivoted about a vertical axis. The coils are connected in series and so arranged that the direction of winding of one of the coils can be reversed with regard to the other by means of a switch. In this way the electromotive force induced in the former coil can be added to or subtracted from that induced in the latter. When the coil with the larger area-turns is placed in the minimum position for signals induced by the arriving waves, the smaller coil is in the maximum position. In this position, on throwing over the switch from one position to another, no change of signal strength will be heard in the telephones attached to the receiving circuit, and the larger coil will be perpendicular to the direction of travel of the waves. Consideration of the theory of this system shows that the operation of the reversing switch is really equivalent to swinging a single frame, or the search coil in a Bellini-Tosi installation, through an angle on either side of the minimum position. The amount of this equivalent angle of swing depends on the ratio of the area-turns of the two coils of the Robinson system. This ratio is usually arranged so that for good sensitivity this equivalent angle is 20° to 30°.

Since, in using the system, the equivalent coil is swung to positions 20° to 30° on either side of the minimum by the action of the switch, the received signals are not reduced to zero intensity. The system is therefore suitable for use where the finding of the zero position is difficult through extraneous noises or interference, and it is, accordingly specially adaptable for use in aircraft.

All the three systems of direction finding are liable under certain conditions to errors which may be classed under three heads: (*a*) variable errors arising from causes influencing the direction of travel of the waves during their propagation through space, (*b*) errors due to the effect of the local surroundings of the receiving station, (*c*) instrumental errors.

A discussion of the three systems of direction finding as regards their basic principles and as regards their liability to the above three classes of errors has recently been published as Special Report [1] No. 1 of the Radio Research Board under the Department of Scientific and Industrial Research. The conclusion reached in this report based on a large number of careful observations is that each system is liable to errors of the same order of magnitude. The errors due to the location of the directional finder can be avoided, however, by careful selection of the site of the station, while instrumental errors can be reduced to practically negligible amounts by suitable design and arrangement of the apparatus. Until recently it appears to have been generally held that observations with undamped waves were more liable to error than those with damped waves. Experiment has shown, however, that the errors observed were occasioned by the heterodyne method of reception of undamped waves, and that they may be eliminated almost entirely by careful screening and arrangement of the heterodyne with regard to the receiving apparatus and aerial system.

The variable errors, falling under class (*a*), however, present much greater difficulty and so far no means of eliminating them have been found. Since they are introduced by changes in the direction of travel of the wave front during propagation the explanation of the factors which give rise to them is to be sought in the study of the propagation of waves. The fact that all the systems of direction finding are in their essentials equivalent to rotating the single turn rotating loop, is of great importance in this respect because in considering the effect of different wave fronts it is only necessary to consider the behaviour of the simplest type of aerial (*i.e.* the single coil type). The results of experiments carried out on one system then can safely be considered as applicable to the other two.

By any of the three methods discussed the direction of the horizontal component of the resultant magnetic field in the wave front can be determined. In practice, however, it is the direction of the horizontal component of the line of motion of the waves which is actually required. Should neither the direction of travel of the waves nor their resultant magnetic field be horizontal, then the setting of a coil in the minimum position for signal strength will have no necessary relation to the direction of arrival of the waves, and errors will be recorded by all three systems. On the other hand, provided the resultant magnetic field remains horizontal, the wave front may be inclined at any angle; or again, provided the wave front remains vertical, the resultant magnetic field may have any angle therein, without causing errors to occur in the observation of the direction. The variable errors are far greater by night than by day. The variation produced may arise very suddenly and the observed bearing may change at the rate of several degrees a minute, or the deviation in the bearing may remain steady for a considerable period. The magnitude of night variations, which are far greater than those due to location or to instrumental errors, may be judged from the following observations recorded in the Special Report of the Radio Research Board already referred to. In one series of experiments where observations were carried out with a Standard Robinson set and a portable type Bellini-Tosi set, erected in the same field at Slough, on various fixed transmitting stations employing waves between 2000 and 5000 metres, the maximum variation for Karlsburg observed with the Robinson set was 27·1° and with the Bellini-Tosi set 28°, for Moscow 9·9°, 9·2°, for Coltano 10·8° and 7·2° respectively. In another series of experiments, on waves of 2000 to 9000 metres, carried out at Orfordness with a permanent Bellini-Tosi apparatus and a standard Robinson set, the total variations at night ranged on various occasions from 5·0° to 54° for the Bellini-Tosi set and 5·2° to 51·3° for the Robinson set.

It should be remarked, however, that these large

[1] A discussion of the practical systems of Direction Finding by Reception, Dr. R. L. Smith Rose, and R. H. Barfield (Radio Research Board Special Report No. 1), published by H.M. Stationery Office. Price 9*d.* net.

variations occurred in cases where the distance between the transmitting and receiving station was great—being rarely less than 100 miles and in some cases as great as 1500 miles. Also the waves had travelled for considerable distances over land. These facts probably account for the changes in the apparent direction of travel of the wave front necessary to produce the large variations observed. Fortunately in the application of radio direction finding to navigation such conditions as a rule do not occur. Ships usually require their positions or bearings to be given when they are nearing land, and there is a considerable amount of evidence to show that, in the case of the shorter waves, as used by ships, passing entirely over sea for distances of the order of 50 to 80 miles, individual bearings very rarely show a maximum error of more than 5°, while simultaneous observations carried out on the same waves after passing over land frequently show variations of the order of 40°.

From the experimental evidence available it would seem that with a suitably situated shore direction finding station a ship at a distance of the order of 50 miles can be given a bearing, under normal conditions, with an accuracy to 1° to 2°. A single direction finding station can only give a ship her bearing from the receiving station, but if a second direction finding station suitably placed with respect to the first is available, two bearings can be given and the position of the ship can be fixed by their intersection. Experience has shown that such an intersection is usually sufficiently correct to enable a ship's position to be given with all the accuracy necessary for safe navigation.

O. F. B.

The Education of the People.[1]

By Prof. T. PERCY NUNN.

IN education, as in all the great fields of practice, there are, and must constantly arise, problems that can be solved only by patient application of the methods of science, but however far the scope of educational science may extend, the critical educational issues will always lie beyond it. For in its origin education is a biological process which does not wait for deliberation to call it into existence or for science to guide it, but has the inevitability of behaviour rooted in instinct.

What is it, then, that determines the general character of the educational process at a given point in the history of a human society? The answer is that the same *élan vital* which brought the society to that point urges it so to train its young that they may maintain its tradition and ways of life. It follows that the education a nation gives its children is, perhaps, the clearest expression of its *ethos* and the best epitome of its scheme of life. Thus the ideas of too many of our Georgian forefathers upon the education of the masses corresponded faithfully with their belief in the great principle of subordination about which Johnson and Boswell talked so often and agreed so satisfactorily. One remembers, for example, how hotly Miss Hannah More denied the scandalous rumour that she was teaching the poor of Cheddar to write! Similarly, the liberal curriculum of our elementary schools reflects the prevalence to-day of a widely different view of the nature and purpose of society. In brief, it is an expression of the steadily growing belief, first, that every member of society has an equal title to the privileges of citizenship; and, secondly, that the corporate strength of society should be exerted to secure for him actual as well as theoretical possession of his title.

How the movement based upon that belief will ultimately affect the happiness of our people no one can with certainty foresee; nevertheless, I am bound to record my opinion that in its main tendency it ought wholeheartedly to be accepted. I think this chiefly because it seems to be inspired by the Christian principle of the immense value of the individual life, or, if you prefer to put it so, by the Kantian principle that no man ought to be treated merely as a means but always also as an end in himself. But if the movement is accepted, public education must correspondingly assume a character which would follow neither from the principle of subordination nor from the principle of *laissez faire*. The view I submit is that the education of the people should aim at enabling every man to realise the greatest fullness of life of which he is by nature capable—"fullness" being, I add, measured in terms of quality rather than of quantity, by perfection of form rather than by amount of content. That view is the basis of all I have to say.

During the last century we learnt, following Darwin, to look upon all biological phenomena as incidents in a perpetual struggle wherein the prizes to be won or lost were the survival of the individual and the continuance of his species. From this point of view there could be only one object of life, one *causa vivendi*, namely, to continue living, and the means by which it was to be attained were adaptations to environment achieved by an individual, and perhaps handed on to its offspring, fortunate germinal variations, or lucky throws of the Mendelian dice. It was natural, if not logically necessary, that the doctrine should fuse with the view, as old as Descartes, that life is but an intricate complex of physico-chemical reactions. Upon that view, even to speak of a struggle for existence, is to use a metaphor admissible only on account of its picturesque vigour; when we study the forms, processes, and evolution of living beings we are spectators merely of the operation of physical and chemical laws in peculiar forms of matter.

These ideas, in either their more moderate or their more drastic form, affected the attitude of men towards matters lying far outside the special province of biology. National policies have been powerfully influenced by them, and it has been widely held that the education of children should be shaped mainly, if not solely, with the view of "efficiency" in the struggle for existence. It is, therefore, relevant to point out what tremendous difficulties are involved in their thorough-going

[1] From the presidential address delivered to Section L (Educational Science) of the British Association at Liverpool on September 14.

application. I will not speak of those which have driven physiologists of high standing to reject the mechanistic theory of life as unworkable, for they do not bear directly upon my argument. It will be more to our purpose to raise, as William James did in his great treatise on psychology, the question of the higher æsthetic, moral, and intellectual qualities and achievements of man, and to ask how these are to be brought under the conceptions before us. We will not press the question how the emergence, say, of Beethoven's Fifth Symphony is to be explained in terms of physics and chemistry; for even the most stalwart mechanists scarcely expect that it will actually be done; they only believe that conceivably it could be done. But it is both fair and necessary to ask how the things of which the symphony is typical can be accounted for on the principle of survival-value. James, facing this question with characteristic candour, felt bound to admit that they have "no zoological utility." He concluded, therefore, that the powers and sensibilities which make them possible must be accidents—that is, collateral consequences of a brain-structure evolved with reference not to them but only to the struggle for material existence. The premises granted, I do not see how the conclusion can be avoided; but surely it is extremely unacceptable. If, with Herbert Spencer, we could regard art merely as something wherewith to fill agreeably a leisure hour, we might be satisfied by the hypothesis that our sensibility to beauty in form, in colour, and in sound, is an "epi-phenomenon" having no significance in relation to the real business of life. But when we think of men whose art was in truth their life, and consider how eagerly the better part of mankind cherishes their memory and their works, it is next to impossible to be satisfied with that view. Take the case of science. Votaries of pure science often seek to justify their ways to the outer world by the argument that discoveries which seemed at first to have only theoretical interest have often disclosed immense practical utility. It is a sound enough argument to use to silence the Philistine, but would the pursuit of science lose any whit of its dignity and intrinsic value if it were untrue? I will not lengthen the argument by extending it to the saints and the philosophers, for its point should be sufficiently plain. The activities of "our higher æsthetic, intellectual, and moral life" have such intrinsic worth and importance that to regard their emergence as accidental and biologically meaningless is outrageously paradoxical. They must be at least of equal significance with anything else in man's life, and may not unreasonably be held to contain the clue to life's whole meaning.

It may be helpful to put the conclusion in other language. Man's life is a tissue of activities of which many are plainly *conservative* in nature, their function being directly or indirectly to maintain the existence of the race and the individual. Agriculture, industry, defence, medicine, are obvious examples of the type. But there are other activities—art and pure science are capital examples—the character of which is best indicated by the term *creative*. The point made is that in any sane view of human life as a whole the creative must be regarded as at least as significant and important as the conservative activities.

Purely conservative and purely creative activities, if indeed they exist, are only limiting instances; in most, if not in all activities, the two characters are interfused. For example, the motive of pure science is unmistakably creative, yet its extrinsic conservative value is unlimited; on the other hand, the vast industrial organisations of to-day exemplify activities which, though conservative in their genesis, yet have developed the creative character in an impressive degree. Considerations of this kind prepare one to see that the higher creative life, far from being merely a splendid accident, is really the clearest and purest expression of the essential character of life at all its levels. The poets are, as the Greeks called them, the supreme *makers*, for all making has in it something of the stuff of poetry. In short, there is no life, however humdrum, however crabbed by routine, which is not permeated by the self-same element, the inflorescence of which is literature, art, science, philosophy, religion.

The foregoing discussion has a close bearing upon the questions what should be taught and in what spirit the teaching should be given. The curriculum always *will* be a partial reflection of the actual life and traditions of a community, and *ought* to reflect all the elements therein which have the greatest and most permanent value and significance. Without doubt these will, in general, be the things that have the highest significance and value for the human family as a whole, but there can scarcely be said to be a common human tradition. There exists, it is true, a common European tradition based mainly upon the Græco-Roman and Christianity, and it is vastly important for the happiness of the world to deepen and vivify men's consciousness of it. But even this lacks the concreteness needed to form the basis of popular education. In short, a nation is the largest social unit whose *ethos* has the necessary individuality. Hence, though we should aim at making our young people "good Europeans," we can do so only by shaping them into that particular brand of good Europeans who are rightly to be called good Englishmen. Hence the importance of fostering in our elementary schools the special traits of the English character at its best; of giving English letters a chief place among the studies of our youth; of cherishing the English traditions in the arts and crafts, including our once proud art of music; even of reviving the old dances which were so gracious and typical an expression of our native gaiety and manners.

Lest this contention should be misunderstood, I add that I preach neither the hateful doctrine that what is foreign should, as such, be excluded, nor the ignorant and presumptuous doctrine that what is our own is necessarily the best, and that we have nothing to learn from other peoples. The whole burden of my argument is that the things which have universal human value are the things of most importance in education. But the universal can be apprehended only where it lives in concrete embodiments. In the cases we are concerned with, these are elements or organs of a national culture; and the only national culture to which a child has direct and intimate access is his own. He should be taught to see, as opportunity permits, how much of it is derived from the common European tradition and how much it owes to the influences of

other national cultures; but it should, in its concrete individuality, be the basis of his education.

Lastly, I have urged that among the strains or currents in a national tradition the highest value belongs to those that are richest in the creative element. These are themselves traditions of activity, practical, intellectual, æsthetic, moral, with a high degree of individuality and continuity, and they mark out the main lines in the development of the human spirit. Do we not rightly measure the quality of a civilisation by its activities in such directions as these? If so, must not such activities be typically represented in every education which offers the means to anything that can properly be called fullness of life?

If the force of the argument be admitted, the principles of the curriculum take a clear and simple shape. A school is a place where a child, with its endowment of sensibilities and powers, comes to be moulded by the traditions that have played the chief part in the evolution of the human spirit and have the greatest significance in the life of to-day. Here is the touchstone by which the claims of a subject for a place in the time-table can be infallibly tested. Does it represent one of the great movements of the human spirit, one of the major forms into which the creative impulses of man have been shaped and disciplined? If it does, then its admission cannot be contested. If it does not, it must be set aside; it may usefully be included in some special course of technical instruction, but is not qualified to be an element in the education of the people.

The same criterion may be applied to the methods by which the subjects of the curriculum are taught. We are constantly told that the "educational value" of a subject lies in the mental discipline it affords, and, from this point of view, a distinction is made between its educational value and its import as an activity in the greater world; thus geometry is taught as a training in logic, the use of tools as "hand and eye training," and so forth. From the point of view I adopt that distinction is unjustifiable and may be dangerously misleading; it has, I fear, often been a source of aridity and unfruitfulness in school teaching. The mistake consists in supposing that the disciplinary value can be separated from the concrete historical character of the subject as a stream of cultural tradition. The discipline of the school workshop consists in using the tools of the craftsman for purposes cognate with his and inspired by his achievements. Similarly the discipline of school geometry consists in steeping one's mind in a certain noble tradition of intellectual activity and in gradually acquiring the interests, mental habits, and outlook that belong to it. To say this is not to minimise the importance of discipline or to expel from school studies the austerity which the grave old word suggests. What is insisted on is that the several forms of mental discipline are characters of concrete types of creative activity, practical, æsthetic, intellectual, and that they influence the mind of the learner favourably only in so far as he pursues those activities as adventures of the human spirit, laborious yet joyous and satisfying, and pursues them after the manner of the great masters. In short, true discipline comes simply by trying to do fine things in the fine way.

The foregoing principles are open to misconceptions against which it is desirable to protect them. In the first place, it may seem that I am designing the education of the people upon a scale which may be magnificent but is certainly impracticable. It is easy, no doubt, to form extravagant expectations, and by seeking to do too much to achieve nothing solid at all. But the argument is concerned far less with the standard to which school studies may be pursued than with their proper qualities and the spirit that should inspire them. In particular, it is directed against the attitude expressed recently by a public speaker who asked what good is poetry to a lad who will spend his days in following the plough and spreading manure upon the fields. Against this attitude it urges that a man's education, whatever his economic destiny, should bring him into fruitful contact with the finer elements of the human tradition, those that have been and remain essential to the value and true dignity of civilisation.

It may be objected, granted the soundness of the ideal, that the shortness of school life makes it impracticable. It is true that a study, to be of real value, must be carried far enough and followed long enough to make a definite and lasting impression. It is also true that some studies can scarcely produce their proper effects until a certain level of maturity has been reached. But what is to be deduced from these admissions? Surely the conclusion, which the public mind is slowly accepting, that so long as children leave school for good at fourteen some of the best fruits of education will be unattainable and the security of the others precarious. It is not merely a question of length of time, but also, and even mainly, of psychological development. The more carefully youth is studied the more significant for after-life the experience during the years of adolescence is seen to be. Its importance is not a modern discovery; for even the primitive races knew it, and the historic Churches have always taken account of it in their teaching and discipline. The case for universal education beyond the age of fourteen depends ultimately upon the importance of shaping the new capabilities of the adolescent in conformity with the finer traditions of civilised life. Public opinion, regretting the generous gesture of 1918, has not at the moment accepted the larger view of the mission of education; but as the nation learns to care more for the quality of its common manhood and womanhood and understands more clearly the conditions upon which that quality depends, the forward movement, now unhappily arrested, will certainly be resumed. For that better time we must prepare and build.

There is another objection to which I should think it unseemly to refer if it were not a stumbling-block to so many persons of good will. A liberal public education will, they fear, make people unwilling to do much of the world's work which, though disagreeable, must still be carried on. The common sense of Dr. Johnson gave the proper reply a hundred and fifty years ago. Being asked whether the establishment of a school on his friend Bennet Langton's estate would not tend to make the people less industrious, "No, sir," said Johnson, "while learning to read and write is a distinction, the few who have that distinction may be the less inclined to work; but when everybody learns to read and write it is no longer a distinction. A man

who has a laced waistcoat is too fine a man to work; but if everybody had laced waistcoats, we should have people working in laced waistcoats."

Lastly, the ironical may ask whether it is an error to suppose that the education of the people should furnish them with useful knowledge and abilities. Now the test of utility which the plain man applies to education is, in principle, sound and indispensable: the only point doubtful is whether the test is always based upon a sufficiently broad idea of utility. The only satisfactory definition of the useful is that it contributes definitely and positively to fullness of life. From that point of view it is useful to teach a ploughboy to love poetry and not useful to teach a public schoolboy to hate Greek. This is not an argument against teaching a subject the disappearance of which from our education would be an irreparable disaster. It means merely that the literatures of the ancient world, when taught, should be taught in such a way as to contribute positively to the quality of a modern life. But the term "useful," according to the definition, certainly includes utility in the narrower sense. The daily work of the world must be kept going, and one of the essential tasks of the schools is to fit the young to carry it on under the immensely complicated conditions of present-day civilisation. The only limitation imposed by our argument is that what is conservative in purpose shall be creative in its method and, being so, shall embody some dignified tradition of practical, æsthetic, or intellectual activity. The condition may be satisfied by a technical education based upon many of the great historic occupations of men and women, provided that inspiration is sought from the traditions of the industry or craft at their noblest. To conceive "secondary education for all" as meaning "the grammar school curriculum for all" would be to make a most serious blunder. The only mistake more serious would be to exclude adolescent boys and girls, even of the humblest station, from any essential part of the national inheritance of culture. But this error may be avoided while full account is yet taken of the far-reaching differences in the talents and *ingenium* of individuals and the rich diversity of the valuable currents, intellectual, practical, and æsthetic, in the life of the community, of which any one may be made the basis of a course truly liberal in quality.

The last hundred years have greatly accentuated the gravity of a problem which was discerned by the poet Schiller and diagnosed in the famous "Letters on Æsthetic Education" he published in 1795. In Schiller's view the immense progress of the modern nations has been purchased at the expense of the development of the individual soul, so that, in spite of the greatness of our achievements, we are, man for man, inferior to the various and well-rounded Athenians of the best days. It is the division of labour essential to a large-scale organisation of society which has at once made general progress possible and individual impoverishment inevitable, for it has cut individual men off from experiences that are indispensable to the full well-being of mankind. If this was true in the days of the French Revolution, how much more true it is to-day, and how much more grave the evil. We are told that before the era of industrialism the great mass of our people enjoyed a culture which, though simple, was sincere and at least kept them in touch with the springs of beauty. What truth there is in the picture I do not know, but it is certain that with what is called the industrial revolution the conditions that make it credible largely disappeared. Torn from the traditions of the old rural life and domestic industry and herded into towns where in the fight for mere existence they lost their hold on all that gave grace to the former life, the folk who now constitute the bulk of our population were cut off effectually from "sweetness and light." That was the situation when the task of public education was taken seriously in hand, and that, notwithstanding a great amelioration in details, is for far too many the situation to-day.

There are some who think that the only remedy is to cry halt to the modern movement and return deliberately to medievalism. That is a counsel of despair; instead of indulging idle dreams it will be more profitable, assuming the unalterable conditions of modern life, to consider how the rest may so be modified as to place the true dignity and grace of life within the reach of all who are qualified to achieve them. That can be done only by a system of education which brings the things of enduring and universal worth to the doors of the common people. It is what has been done by many an elementary school teacher, sometimes with scant assistance from public opinion, simply because, face to face with his helpless charges, he was impelled to give them the best he had to give. It will be done with increasing happy results the more clearly it is seen that the proper function of the elementary schools is something much more than to protect the State against the obvious danger of a grossly ignorant populace or to "educate our masters" in the rudiments of citizenship. Unless it be done, unless the natural hunger of the people for knowledge and beauty be wisely stimulated and widely satisfied, no material prosperity can in the end save the social body from irretrievable degradation and disaster.

New Discoveries and Paintings of Palæolithic Date in the Department of the Lot (France).

THE study of palæolithic man is many-sided. As a geologist, treating the tools and objects manufactured by prehistoric man as fossils, the prehistorian has determined an archæological sequence, and, by correlating this with the geological record of the earth's history, has been able to suggest a probable chronology. As an anatomist, the prehistorian has launched into the fascinating study of the evolution of man, and, although hampered by lack of authentic material, has already been able to show that this evolution was by no means a simple straightforward affair. As fresh material comes to hand it will become possible to elucidate further this complex branch of the subject. As an ethnologist, the prehistorian has attempted to trace the migrations of prehistoric races, and to compare their cultures with those of primitive folk still surviving.

But perhaps the most entrancing branch of prehistory is the study of the mural art of these very early peoples. Here we are not dealing merely with "dry bones" or objects made for some immediate and concrete use, nor indeed are we dealing, in the vast majority of cases, with mere "home" decoration. Primitive man, then as now, was concerned with his food supply, and the art was practised as a form of sympathetic magic. The veil lifts for a moment, revealing to us the very thoughts and aspirations—one might almost say the religion—of these early artists. The occurrence of prehistoric ceremonial burials has further helped in this study, indicating, as it probably does, something of the nature of a cult of the dead. Perhaps some of the cave art may be connected with this.

The palæolithic art for magic purposes occurs emblazoning the walls of caves. The darkness and silence of these entrances to the bowels of the earth is eminently suited to the production in primitive man of a state of mind receptive to magic influences. There is actually evidence to suggest that a priestly artist caste guided and controlled these emotions. The painted and engraved caves may indeed be described as prehistoric temples.

For this art to be practised, it is clearly necessary that natural caves should occur in the district. Hitherto three main areas of distribution have been located, one in Dordogne (France), around the village of Les Eyzies on the banks of the river Vezère, a tributary of the Dordogne; another in the Pyrenees, especially in the department of Ariège; the third in Cantabria (North Spain), and extending as far west as Asturias. It would now appear that, thanks to the energy of the Abbé Lemozi of Cabrerets near Cahors (Lot), a new region is in process of discovery. An announcement of this has appeared in *L'Illustration* of October 13, p. 354. The article, profusely illustrated, deals with the finds of the Abbé Lemozi. It does not pretend to be a scientific exposition written by an expert. On the other hand, an exceedingly interesting sketch is given of the archæological work done by the Abbé, which it is to be hoped he will publish himself in due course. Not only have a number of prehistoric "homes" been discovered under overhanging rocks, many of which have yielded rich industries in stone and bone, but a painted cave temple, worthy to be compared with those of the Dordogne, Pyrenees, and Cantabria, has also been explored.

Judging from the illustrations, the date of the art would seem to be in part Aurignacian, in part lower Magdalenian, but it is impossible to be precise on this point from the meagre account given. The animals and figures observed apparently include reindeer, horse, mammoth, bison, "negative" human hands, signs, etc. Obviously much further work is required before what promises to be a new and rich area is properly explored, but the Abbé is to be congratulated on what he has already done, and *L'Illustration* is to be highly commended for having brought forward his work in such an excellent way. A complete survey of the district around Cabrerets, with a scientific account of the diggings and of the cave art, will be eagerly awaited by all prehistorians. Some reproductions of the new prehistoric paintings appeared in the *Illustrated London News* of October 20.

M. C. B.

An African Chalicothere.

By Dr. CHAS. W. ANDREWS, F.R.S.

A SMALL collection of fossils from the neighbourhood of Albert Nyanza has recently been sent for determination to the British Museum by Mr. E. J. Wayland, director of the Geological Survey of Uganda. The beds from which these remains were derived are of late Pliocene or, more probably, Pleistocene age, since they include teeth of Hippopotamus and Phacochœrus which do not seem to be distinguishable from those of recent forms: with these are bones of crocodiles, Chelonia, a large Siluroid fish, and fresh-water shells.

Accompanying these remains there are two or three fragments of much greater interest. The most important is a phalangeal bone of such peculiar form that it is at once seen to belong to a member of the Ancylopoda (Chalicotheroidea). These animals are very aberrant perissodactyl ungulates in which, instead of hoofs, great cleft claws are developed, and the consequent modification of the foot bones is such that even a single phalangeal bone is easily recognisable. These large cleft claws were known so long ago as Cuvier's time, and he regarded them as belonging to a giant Manis ("Pangolin gigantesque"). It was not until 1888 that Filhol was able to prove that they actually belong to an ungulate. The group first appears in the Middle Eocene of North America, and in later times it spread over the northern hemisphere, remains being found in the Upper Miocene beds of Samos and Pikermi, and in India and China in deposits as late as the Pleistocene.

The finding of a Chalicothere in Central Africa is of especial interest because a species occurs in Samos associated with Samotherium, which is very closely similar to the Okapi, the discovery of which a few years ago attracted so much attention. It seems just possible that a Chalicothere may still survive in the same region and may be the basis of the persistent rumours of the existence of a large bear- or hyæna-like animal. For example, in a letter to Mr. M. A. C. Hinton from Capt. C. R. S. Pitman, of Kenya Colony, the writer inquires if anything is known of the "Nandi Bear," stories of which are constantly cropping up. Whatever it may turn out to be, the beast seems to be nocturnal in its habits and to resemble a very large hyæna, an animal in which the proportions of the fore and hind limbs are much as in some Chalicotheres.

It is to be hoped that great efforts will be made to settle what this creature is, since, if the suggestion made above turns out to be correct, it will be a discovery of far greater interest than the Okapi. It does not seem at all improbable that, in such a country, even a large nocturnal animal might escape notice for a long time: even in England few people have ever seen a badger in the wild state.

Obituary.

The Hon. N. C. Rothschild.

By the death on October 12, at the age of forty-six, of the Hon. Nathaniel Charles Rothschild, younger son of the first Lord Rothschild, Nature in a literal sense, entomology, and, it may be added, tropical medicine have each sustained a formidable blow. For Mr. Rothschild, whose career demonstrated in striking fashion that the pursuit of business is by no means incompatible with scientific achievement of the first rank, was at one and the same time an active partner in the firm of Messrs. N. M. Rothschild and Sons; the mainstay of the Society for the Promotion of Nature Reserves, to which he contributed practically all the funds at its disposal; and the leading authority on the Siphonaptera, or fleas, certain species of which are responsible for the dissemination of plague.

In 1895, on leaving Harrow, where, in conjunction with the late J. L. Bonhote, he had already while still a schoolboy produced a volume on the local butterflies and moths, Charles Rothschild went up to Trinity College, Cambridge, where three years later he obtained honours in Part I. of the Natural Sciences Tripos. After entering the City, besides devoting himself to his more immediate interests at New Court, Mr. Rothschild became chairman of the Alliance Assurance Company. The outbreak of the War caused him to become closely connected with, and to undertake most important work for, more than one Government Department; and his father's various duties, which were assumed by Mr. Rothschild on the death of the former in the spring of 1915, added to the strain of his many responsibilities. Overwork, cruelly prolonged, resulted in 1916 in a nervous breakdown, and from this Charles Rothschild never fully recovered; so that his lamented death at a comparatively early age was clearly an after-result of the War.

Mr. Rothschild, who was a Justice of the Peace and had been High Sheriff for Northamptonshire, was also a lieutenant for the City of London, and was president of the Entomological Society of London in 1915 and 1916. In addition, he was a fellow or member of many scientific and learned societies both at home and abroad, and had been a member of the honorary committee of management of the Imperial Bureau of Entomology, from the formation of the latter, as the Entomological Research Committee, in 1909. His presidential address to the Entomological Society on January 19, 1916, consisted in the main of an earnest plea for the preservation of many species among the British fauna and flora, now fast disappearing, or on the verge of, at any rate, local extinction; and appealed for support for the Society for the Promotion of Nature Reserves, and for the work of the National Trust for the Preservation of Places of Natural Beauty or Historical Interest.

Even in these days of specialisation, it is given to few zoological systematists to possess an encyclopædic and practically unique knowledge of an entire group. But Charles Rothschild soon became, as he remained until the end, the leading authority upon Siphonaptera; and to him, more than to any other, existing, accurate knowledge of the fleas of the world is due. Prior to Rothschild's day, the study of Siphonaptera lagged far behind that of most other orders of insects, and in fact, with a few notable exceptions, such as Taschenberg and C. F. Baker, had been almost entirely neglected by entomologists. Rothschild, however, was a prolific writer upon his favourite subject, and, while steadily accumulating his unrivalled collection of fleas, both exotic and endemic, he continued for a quarter of a century to diagnose and describe his material in a series of papers and monographs of the utmost value. The first papers by Mr. Rothschild on Siphonaptera (diagnoses of two new species of British fleas) appeared in 1897, when their author was but twenty years of age. Subsequently his interest was extended to the Siphonaptera of the entire world, and, in the interval between the appearance of his earliest contributions and last year, when the latest memoir written by him (a report upon the Siphonaptera collected by the Norwegian Expedition to Novaya Zemlya in 1921) was published, he was responsible, either singly or in conjunction with Dr. K. Jordan, his gifted collaborator, for a very large number of authoritative contributions to the literature of this group of ectoparasites.

Some ten years ago Mr. Rothschild, who was a generous and frequent benefactor to the Natural History Departments of the British Museum, presented to the Trustees of that institution his entire collection of Siphonaptera and other ectoparasites, with the proviso that the collection should remain in his hands during his lifetime. It is understood that the donor also set apart a sum of money, the interest of which, when the collection is handed over to the nation, is to be applied to its maintenance and improvement. E. E. A.

Mr. William Thomson.

Mr. William Thomson, F.R.S.(Ed.), F.I.C., the eminent Manchester consulting chemist and analyst, who died suddenly in his Laboratory on October 4, was a prominent figure in the chemical circles of Manchester and London during the last fifty years. Born in 1851 in Glasgow, he went to Manchester in 1869, and entered as assistant to Dr. Crace-Calvert at the Royal Institution Laboratory in Princess Street. Four years later, on August 25, 1873, at the age of twenty-two, he became a partner in the firm of Crace-Calvert and Thomson, and on the death of Dr. Crace-Calvert two months afterwards, took sole charge of the practice, and combined with this the office of public analyst for Stockport, which he continued to the time of his death.

Mr. Thomson joined the Manchester Literary and Philosophical Society in 1873, and served on the council for many years, acting as president from 1917 to 1919. The Society is the richer for his contributions on different subjects of scientific interest, some of which during his lifetime developed into renowned discoveries. Only in November of last year he presented to the Society the actual tubes containing sulphides of calcium, barium, etc., with which in 1877 he brought to the notice of Sir William Crookes the phosphorescent properties of these substances. They proved to be the first of three steps which led to the discovery of X-rays by Prof. Röntgen. He is also known for his work on the detection of arsenic in beer during the

outbreak of arsenical poisoning some years ago, and for his indefatigable and original work on the amount of soot in the smoke-laden atmosphere of Manchester. His efforts in association with the Manchester and Salford Sanitary Association to obtain a purer atmosphere should be a memorial to him among the public of that city.

In recognition of his many original contributions to science, Thomson was elected a fellow of the Royal Society of Edinburgh in 1876. He was also one of the original members of the Society of Chemical Industry, was elected to the committee in October 1884, and acted as chairman of the Manchester Section for some years. He was a prominent member of the Institute of Chemistry, of which he was elected a fellow in 1877; he served on the council from 1887 to 1890 and from 1893 to 1896. For some years also he was on the committee of the Society of Dyers and Colourists. He was the author of a book on "The Sizing of Cotton Goods," of which the first edition was published in 1877 and the second in 1879.

SIR WILLIAM RICE EDWARDS, K.C.B., K.C.I.E., C.M.G.

THE death on October 13 of Major-General Sir William Rice Edwards from pneumonia, after a very brief illness, at the comparatively early age of sixty-one, has come as a great shock to his many friends, and especially to the members of his service, who trusted and honoured him as their chief and loved him as an upright and sporting gentleman. He studied at the London Hospital, took the M.B. with honours and later the M.D. of Durham, and entered the Indian Medical Service in 1886, serving in his earlier years at the Eden Hospital, Calcutta, and on Lord Roberts's staff in India and later during the South African War, and was Residency Surgeon in Kashmir for some years before selection for the administrative grade. After a successful period as Surgeon-General, Bengal, where his abilities and accessibility endeared him to all who had the privilege of serving under him, he succeeded Sir Pardey Lukis in 1918 as Director-General at the most critical period in the history of the Indian Medical Service. He fought unflinchingly, without the least regard to his personal prospects, for the Service, first to obtain justice with regard to the increased pay recommended by the Public Services Commission, and afterwards to lessen, so far as possible, the disastrous effects of the Montague reform scheme. He succeeded in the first, with the help of the British Medical Association, but regretfully admitted, when speaking as chairman of the I.M.S. dinner only last June, that he had failed to a large extent in the latter superhuman task. He did much to foster the scientific work of the bacteriological department, while the successful organisation of the Calcutta School of Tropical Medicine was due in no small degree to his invaluable support.

BY the death, on September 4, of Prof. Dr. Paul Friedländer another favourite and successful pupil of Adolf von Baeyer has passed away. He had many friends and was highly esteemed by his colleagues beyond the boundaries of his native country. Paul Friedländer was born in 1857 at Königsberg, Prussia, where, having finished his school education, he began his academic studies under Graebe, and continued them in Strasbourg and Munich under A. v. Baeyer in 1878, whose private assistant he was at the time. From 1884 to 1887 Friedländer was chief chemist of the scientific laboratory of the Oehler Works at Offenbach a.M. Afterwards he entered upon his academic career in 1888 at Karlsruhe, where he was made professor-extraordinary in 1889; from 1895 to 1911 he was professor at the Museum of Industrial Technology in Vienna, whence he passed to Darmstadt as professor of chemistry of dyestuffs. Friedländer's most important work was connected with the group of indigo dyes; he found that the ancient Tyrian purple, the dyestuff of the shellfishes, contains highly brominated indigo derivatives; his discovery of thio-indigo red, a sulphur derivative of indigo, was most important in the development of vat dye manufacture, and enabled Friedländer to find a number of new compounds. His main literary work is well known and in daily use by colour and dyestuff chemists, though, so far as we know, published in German only.

MR. ARTHUR L. DEARLOVE, who died on October 19, was a well-known consulting engineer. He was senior partner in the firm of Messrs. Clark, Forde and Taylor. He superintended the laying of many thousands of miles of submarine cable, and did a large amount of cable work during the War. He did much careful research work on the Clark and Weston standard cells, and contributed largely to the technical journals.

WE regret to announce the following deaths:

Prof. Carl Harries, honorary professor of the Technical High School at Charlottenburg, and formerly professor of chemistry at Kiel, who was known for his work on the action of sodium on isoprene, aged fifty-seven.

Prof. P. W. Latham, formerly Downing professor of medicine in the University of Cambridge, on October 29, aged ninety-one.

Dr. Charles Frederick Millspaugh, curator of the department of botany of the Field Museum, Chicago, and professor of botany at the University of Chicago and the Chicago Medical College, on September 15 aged sixty-nine.

Prof. F. P. Spalding, of the School of Engineering of the University of Missouri since 1900, on September 4, aged sixty-six.

Dr. J. E. Stead, F.R.S., president of the Iron and Steel Institute 1920–21, on October 31, aged seventy-two.

Dr. A. Stutzer, the well-known agricultural chemist of the University of Königsberg, who has carried out many researches both alone and with collaborators on Chile saltpetre, soil organisms, and nitrifying and denitrifying bacteria, on September 3, aged seventy-four.

Prof. James Sully, emeritus professor of philosophy, University College, London, on November 1, aged eighty-one.

Current Topics and Events.

H.M. the King has approved of the following awards this year by the president and council of the Royal Society:—A Royal medal to Sir Napier Shaw, for his researches in meteorological science; a Royal medal to Prof. C. J. Martin, for his researches on animal metabolism. The following awards have also been made by the president and council:—The Copley medal to Prof. H. Lamb, for his researches in mathematical physics; the Davy medal to Prof. H. B. Baker, for his researches on the complete drying of gases and liquids; and the Hughes medal to Prof. R. A. Millikan, for his determination of the electronic charge and of other physical constants.

The following is a list of those recommended by the president and council of the Royal Society for election to the council at the anniversary meeting on November 30:—*President*: Sir Charles Sherrington; *Treasurer*: Sir David Prain; *Secretaries*: Mr. W. B. Hardy and Mr. J. H. Jeans; *Foreign Secretary*: Sir Arthur Schuster; *Other Members of Council*: Sir Frederick Andrewes, Prof. C. G. Barkla, Sir William Bragg, Prof. W. E. Dalby, Prof. A. S. Eddington, Prof. T. R. Elliott, Prof. E. S. Goodrich, Sir Sidney Harmer, Sir Thomas Holland, Sir Frederick Keeble, Prof. T. R. Merton, Prof. H. F. Newall, Prof. D. Noel Paton, Dr. A. Scott, Mr. F. E. Smith, and Prof. J. F. Thorpe.

On Saturday, November 3, His Majesty the King of Sweden, accompanied by Baron Palmstierna, the Swedish Minister, and the Royal Suite, visited the Linnean Society's rooms in Burlington House, and was received by Dr. A. B. Rendle, the president, the officers, council, and staff. An inspection was made of the various objects of interest connected with the great Swedish naturalist, Carl von Linné, such as his herbarium and zoological collections, manuscripts, correspondence, and volumes copiously annotated by their author. Before leaving, the King signed the Roll and Charter Book of the Society, on the emblazoned vellum page specially prepared for signature.

According to a telegram from New York which appeared in the *Times* of October 31, an expedition of the Smithsonian Institution, of which Dr. J. P. Harrington is the head, has discovered, at Santa Barbara, in California, two human skulls for which a very high antiquity is claimed. They are said to belong to an era far earlier than that of Neanderthal man. The evidence upon which this claim is based would appear to be a low forehead and very pronounced eyebrow ridges. The mouth cavity is extremely large and the walls of the skull very thick. They are said to be twice the thickness of ancient Indians' skulls. Until more detailed evidence is available, judgment must be suspended as to the likelihood of this claim to a high antiquity being substantiated; but it may be pointed out that skulls exhibiting Neanderthaloid characteristics, especially in the pronounced eyebrow ridges, have been found on more than one occasion in the United States. Although a great age has been attributed to them, upon further examination they have been pronounced to be merely a relatively modern variety of the Indian type. It is significant that the new Santa Barbara skulls were associated with a material culture, implements, fish-hooks, etc., which is said to show a great advance upon any culture that can be associated with Neanderthal man.

The *Times* of November 1 contains an interesting account by its Peking correspondent of some results of the American Expedition to Mongolia organised by Prof. Osborn and led by Mr. R. C. Andrews, which included Mr. W. Granger as palæontologist, and Mr. F. K. Morris as zoologist. The expedition was despatched in consequence of the reported existence of vertebrate fossils in Mongolia. Mr. Andrews, in a preliminary visit to the area, found indications that a systematic search might yield a rich harvest of Mesozoic vertebrates. The expedition with five motors and seventy camels travelled through Kalgan to part of the Gobi Desert—about 300 miles south-west of Urga. Excavations there resulted in the discovery of seventy skulls and twelve complete skeletons. The local conditions are so favourable for the perfect preservation of fossils that fourteen fossil reptile eggs were found, one of which contains an embryo of an unhatched Dinosaur. Five eggs were found in a nest close beside the skeleton of what was presumably the parent reptile. The shells had been cracked and gradually filled by the fine, wind-blown dust which formed the loess. The skeletons are Mesozoic Dinosaurs and are regarded by Prof. Osborn as the ancestors of the famous fossil horned reptiles of Montana. One of them has been named *Protoceratops andrewsi*. Prof. Osborn considers that the Dinosaurs developed in the northern plains of the Old World and thence crossed into America through northern China. The collections are being taken to the American Museum in New York. It is hoped that funds will be raised to continue the work in Mongolia on a still larger scale. Preliminary technical reports on the discoveries have been already published in America, and announced by members of the expedition to the Geological Society of China.

The foundation ceremony at Sukkur in the Province of Sind, India, on October 24, when Sir George Lloyd, the retiring Governor of Bombay, laid a stone which marks the commencement of operations for the construction of an irrigation barrage, is worthy of more than the casual note which has appeared in the daily press. It marks the inception of, perhaps, the largest and most impressive irrigation scheme constructed in any part of the world. Sind, which is one of the driest tracts in India, depends for its irrigation upon inundation canals from the river Indus, the overflow from which is sporadic and fluctuating. In flood times there is a full supply of water; during the cold season only the most fortunately situated areas obtain any supply at all, while a minimum of 20,000 cubic feet of water per second runs waste to the sea. It is the object of the barrage

to regulate the flow so as to secure an adequate supply throughout the year. The barrage structure will be the largest of its kind in the world, far exceeding the Assuan Dam. It will measure 4725 feet between the faces of the regulators on each side. These regulators are seven in number, and of the canals they feed, three will be wider than the Suez Canal, and the central rice canal will have a discharge equal to that of the Thames. The gross area commanded by the works embraces 7½ million acres, of which 6½ million acres are culturable, and an annual area of 5¼ million acres under irrigation is contemplated. The total cultivated area in Egypt is thus exceeded by half a million acres in this one scheme for a single province in India. The estimated outlay on the project amounts to more than twelve millions sterling.

APPARENTLY the principle of organic evolution is still under public discussion in the United States through Mr. W. J. Bryan's campaign against it. The Journal of the Washington Academy of Sciences (vol. 16, No. 13, October) contains the following amusing comments by Dr. C. W. Stiles from the Proceedings of the Biological Society of America, which is affiliated with the Academy: "According to Mr. Bryan's premises, all germs which cause disease must have been created in the beginning as they exist to-day. If it is to be conceded that these germs were originally created in some form other than as disease germs, the theory of evolution stands admitted. Obviously, since Adam was the last animal created and since the animals were not created until after the plants, it is unthinkable that any of the numerous germs which cause disease were created after Adam. Since disease germs are dependent for their existence upon animals and plants in which they cause disease, it is clear that these germs could not have been created or have existed prior to the creation of their victims. A challenge of this deduction would be an admission that the germs were not created as they are to-day, but that they later evolved into disease germs; but this would be an admission of evolution. Therefore, if Mr. Bryan's challenge is to be accepted, we must conclude that Adam harbored every germ disease which is characteristic of man or dependent on man for its life cycle."

A CRITICAL examination of Berthelot's work on Arabic chemistry has been published by Mr. E. J. Holmyard in *Chemistry and Industry* (Oct. 5 and 12). The criticism is arranged under three headings, dealing respectively with Berthelot's qualifications for his task, with his choice of material, and with his treatment of the material chosen. It is concluded that Berthelot undoubtedly possessed the necessary scientific qualifications, but was hampered by having to rely on translations from the Arabic which were not wholly accurate from a technical point of view. He also devoted his attention to three points only, namely, the Arabic originals of Latin works, to the influence of the Greek alchemists, and to the works of Jābir ibn Hayyān and their relation to the Latin works of Geber. The choice of material in the last case was quite inadequate. Berthelot's treatment of the material chosen was arbitrary and sometimes superficial, the most important Latin work at his disposal ("Liber de Septuaginta") receiving insufficient consideration. Although some recent criticism of Berthelot's undoubtedly great services to the history of chemistry has probably gone further than is justifiable, the conclusions of Mr. Holmyard, if accepted, will make it necessary to exercise great caution in following the French author in his treatment of Arabic chemistry. The great gap in our knowledge of the middle period of Arabic chemistry, to which Mr. Holmyard refers, will have to be filled in before any definite conclusions can be drawn as to the general influence of the workers of Islam on the progress of chemical thought. It may even now be asserted, however, that the judgments of previous historians may require modifications in several directions. Although some distinguished Orientalists abroad, notably Prof. E. Wiedemann and Prof. Ruska, have performed most valuable services in the region of Arabic science, the attention of other students is much to be desired.

DR. H. LEVINSTEIN, who is a member of the scientific committee directing the chemical exhibits for the British Empire Exhibition at Wembley, in the course of some remarks made recently, stated that the pure chemistry exhibit is being organised by a committee representing all the relevant scientific societies, supported and greatly assisted by the advice and co-operation of the Royal Society. The intention is to produce an exhibit which will make plain to the world what British men of science have done and are doing to build up the science of chemistry as it is known in the world to-day. The pure chemistry exhibit at Wembley should for ever destroy the illusion, which had some justification in the past, that British university training and research in chemistry is below the highest standard of other countries. This would not have been true in the same sense thirty years ago. The following conveners have agreed to organise the various sections of the chemical exhibit: Sir Ernest Rutherford (structure of the atom), Prof. J. C. McLennan (spectroscopy), Sir Henry Miers (crystallography and crystal structure), Dr. A. Lapworth (valency theories and theories of chemical combination), Dr. T. Slater Price (photography), Prof. F. G. Donnan (general physical chemistry), Dr. Alexander Scott (atomic weight determination), Mr. A. Chaston Chapman (analysis: hydrogen ion concentration), Prof. E. C. C. Baly (general inorganic), Prof. A. Smithells (flame, fuel, and explosion waves), Dr. Henry and Prof. F. L. Pyman (organic chemistry), Mr. J. L. Baker (biochemistry), Sir John Russell (agricultural chemistry), Principal J. C. Irvine (sugars), Prof. G. G. Henderson (terpenes), Prof. I. M. Heilbron (plant colouring matters), Dr. J. T. Hewitt (coal-tar colouring matters), Prof. J. F. Thorpe (general organic chemistry), Mr. C. F. Cross (cellulose), Dr. E. F. Armstrong (catalysis), Mr. W. F. Reid (explosives), Dr. W. R. Ormandy (plastics), Commander

R. E. Stokes-Rees (apparatus), Prof. J. W. Hinchley, (chemical engineering), Mr. R. B. Pilcher (historical).

The first World Power Conference will be held on June 30–July 12 next at the British Empire Exhibition. It has been promoted by the British Electrical and Allied Manufacturers' Association (the B.E.A.M.A.), in co-operation with many technical and scientific institutions. The subject discussed will be the production and generation of energy in all its forms. It is very satisfactory to notice that practically every civilised country is sending delegates, and many engineers of world-wide eminence will read papers on power generation and distribution, and on electric traction. Considering what different solutions have been standardised in the various countries, a comparison of costs will lead to results of permanent value. One point, however, that the promoters of this international conference seem to have overlooked is that the date of the centenary of the birth of Lord Kelvin is on June 26. Few, therefore, of the eminent delegates will be able to take part in the celebration. As Lord Kelvin is admittedly the greatest physicist of the Victorian age, and possibly the greatest natural philosopher since Sir Isaac Newton, foreign men of science and engineers will doubtless want to take part in our celebrations.

The opening meeting of the new session of the Newcomen Society for the Study of the History of Engineering and Technology was held on Friday, October 26, in the appropriate atmosphere of Prince Henry's Room, Fleet Street, when the president, Loughnan St. L. Pendred, delivered his presidential address on "The Value of the History of Technology." Mr. Pendred said he had in the first instance examined what were the views held as to the use of history in general, and, in spite of all that had been written on the subject, he found it impossible to believe, for example, that the events of the Hundred Years War were of the slightest use to us in the recent struggle with Germany or that the Battle of Jutland owed anything to Admiral Mahan's examination of Nelson's orders at Trafalgar. The importance of history resided in its evolutionary characteristics, and in this aspect technology, reflecting as it does the most important endeavours of mankind from the earliest times, is as worthy of serious investigation as those natural causes by which man himself was developed from a lower creation. Strange as it may appear, development has never received a modicum of the attention that is paid to systems of philosophy, yet these have made far less difference to the world than have advances in technology. This is partly the case because, while the documentation of the ordinary forms of history is abundant, that for the relationships of human progress to technical development is scanty. Mr. Pendred also alluded to the value of the historical method in teaching technology and, by inspiration from its achievements, in the formation of character.

October rains were heavy over the British Islands, especially in the midland, western, and south-eastern districts. In London, according to the Greenwich observations, the total rainfall for the month was 5·07 in., falling on twenty-three days. October was by far the wettest month so far this year; the next wettest month was February, with 2·65 in. The monthly total is the heaviest since July 1918, when the fall was 7·35 in.; it is the wettest October since 1882, when the measurement for the month was 5·42 in., though in 1880 the rainfall for October was 7·65 in., the heaviest for the corresponding month for upwards of 100 years. At Greenwich the rainfall this year for the ten months to the end of October is 20·37 in., which is 1·41 in. more than the normal. At Eastbourne the rainfall, measured in the Old Town, for October was 7·48 in., rain falling on twenty-three days; the measurement for twenty-four hours on the morning of October 24 was 1·51 in. In 1889 the October rainfall at Eastbourne was 8·15 in., and in December 1915 the measurement was 8·37 in. The excess of rain at Eastbourne for the last ten months is nearly 7 inches. At the Rothamsted Experimental Station, according to the *Times* of November 3, the rainfall in October measured 4·97 in., an excess of 1·91 in.; of this 3·45 in. drained through 60 inches of soil, against an average for October of 1·67 in., giving an excess of 1·78 in. The soil is saturated, and it seems probable that the winter rains will increase the supply of underground water, which is still deficient.

A general discussion on "Electrode Reactions and Equilibria" will be held by the Faraday Society meeting at the Institution of Electrical Engineers on Monday, November 26. The first session of the meeting will extend from 3 to 5 p.m., and will deal with "Conditions of Equilibrium at Reversible Electrodes." Sir Robert Robertson, president of the Society, will preside, and the introductory address will be given by Dr. E. K. Rideal. Among the speakers will be Prof. Biilman, of Copenhagen, who will read a paper on "Some Oxidation and Reduction Electrodes and their importance to Organic Chemistry." After an interval for tea the meeting will resume at 5.30 p.m., and will devote itself to the consideration of "Irreversible Electrode Effects, including Passivity and Overvoltage." Prof. F. G. Donnan, vice-president, will preside over this session, and the introductory address will be given by Prof. A. J. Allmand. At the conclusion of the meeting a dinner will be held at the Holborn Restaurant to be followed by an informal conference. Members of the Chemical Society, the Physical Society, and the Institution of Electrical Engineers, have been invited to attend this discussion. Others interested should apply to the Secretary of the Faraday Society, 10 Essex Street, London, W.C.2, from whom a full programme may be obtained.

Col. Rookes Evelyn Bell Crompton, past-president, has been elected an honorary member of the Institution of Electrical Engineers.

At a general meeting of the members of the Royal Institution held on November 5, the thanks of the members were returned to Mr. F. Coston Taylor for his donation of one hundred guineas to the research fund, and to Mr. Robert Mond for his gift of busts

and medallions of Dr. Ludwig Mond, Cannizzaro, Liebig, Berzelius, and others; statuette of Sir James Dewar, and many portraits and photographs. The death of Prof. Jules Violle, an honorary member of the Institution, was announced, and a resolution of condolence with the family was passed.

THE Dr. Mann Juvenile Lectures of the Royal Society of Arts for the new session will be delivered respectively by Prof. W. A. Bone and Mrs. J. W. Henshaw. Prof. Bone's lectures will deal with "Fire and Explosions," and be given on January 2 and 9. Mrs. Henshaw's lecture, entitled "Among the Selkirk Mountains of Canada, with Ice-axe and Camera," will be given on January 16. The lecture hour in each case will be 3 o'clock.

A TECHNICAL assistant is required by the Royal Aircraft Establishment, South Farnborough, Hants, whose duties will be research in problems relating to electric ignition. Candidates should possess an honours degree in physics or electrical engineering, or equivalent qualifications, and have had experience of research work in electrical subjects, preferably in connexion with high frequency work. Applications should be addressed to the Superintendent of the Royal Aircraft Establishment, quoting reference A20.

THE Department of Agriculture in Kenya is requiring an agricultural assistant to help the director and deputy-director of agriculture in supervising agricultural work, particularly native agricultural services. Candidates should possess a degree or diploma in agriculture, a good knowledge of tropical agriculture, and have had experience in agricultural practice. Written applications for the post should be sent to the Assistant Private Secretary (Appointments), Colonial Office, Downing Street, S.W.1, upon forms obtainable from the same address.

MR. B. M. HEADICAR, honorary secretary of the Universities' Library for Central Europe, sends us a list of German chemical literature at his disposal for exchange for similar English literature published since 1914. Alternatively any literature of scientific interest would be accepted and a *quid pro quo* exchange is not stipulated. Inquiries may be addressed to Mr. Headicar at the London School of Economics, Clare Market, London, W.C.2. The list includes volumes of the *Berliner Berichte*, *Zeitschrift fur angewandte Chemie*, *Chemiker Zeitung*, "Technisch-Chemisches Jahrbuch," Abegg's "Handbuch der anorganischen Chemie," and *Zeitschrift fur Chemie und Industrie der Kolloide*.

THE October number of the Journal of the Royal Photographic Society is devoted to the Society's Exhibition. It is copiously illustrated and contains several articles which refer chiefly to pictorial matters. But Dr. B. T. J. Glover, of Liverpool, writes as "a technician," and points out, with examples, how often the gradation of the prints is falsified by under exposure, over development, and manipulation, as in the making of gum prints and bromoils. Indeed with regard to bromoils he asks, "Can any one show me a bromoil print in which they [tone values] are right?" As he also gives examples that show "an exquisite quality" resulting from sound photographic technique, a study of his comments cannot fail to be of interest to those who favour pure photography as well as to those who think that photography is not good enough and seek to improve it by what they call "control."

Our Astronomical Column.

A BRIGHT METEOR.—Mr. W. F. Denning writes from Bristol that on November 3, at $6^h\ 23^m$ G.M.T., he observed a large meteor, equal to Venus in brightness, shooting downwards in the southern sky from $295\frac{1}{2}^\circ + 6^\circ$ to $308^\circ - 21^\circ$. The nucleus gave a flash at the end of its flight and left a white streak. The direction of the course of the object was from a radiant point near β Ursæ Majoris, which supplies many meteors at this time of the year and appears to be a well-defined centre of recurrent radiation at various periods of the year. The shower or showers has or have been frequently observed in the last quarter of the year and deserves more thorough investigation.

SPECTROSCOPIC AND TRIGONOMETRICAL PARALLAXES.—A. Pannekoek (*Observatory*, October 1923) gives reasons for believing that the variation of intensity of certain spectral lines is not directly a measure of the star's absolute luminosity, but of the intensity of gravity at its surface, which affects the ionisation of its atmosphere. For the same spectral class the quantity derivable from the spectrum is the ratio of luminosity to mass. The mean spectroscopic parallaxes of groups of stars will not be affected, but those of individual stars will be, if their mass differs from the mean mass of the class. For example, the trigonometrical parallax of ϵ Indi is $0{\cdot}28''$, while $0{\cdot}45''$ has been given as the spectroscopic value. If there is no error in either value, the star's mass is 2·6 times the mean mass of spectral type K5. This would thus appear to be a method of determining the masses of the nearer stars if non-binaries, while the binaries would serve to test the truth of the principle.

W. J. Luyten contributes a paper to Proc. Nat. Acad. Sci. (September 1923) in which he examines the systematic errors of trigonometrical parallaxes. Van Rhijn recently gave reasons for thinking them to be too large from a study of the proper motions and radial velocities. Luyten uses the same material as Van Rhijn, but discusses it differently. He deduces two graphs: one by grouping the stars by measured parallaxes and forming a graph connecting mean apparent magnitude with reduced parallax; the other by grouping according to apparent magnitude, and again forming a graph. He considers that the truth lies between his two graphs, and deduces that the Allegheny parallaxes are not too large, as Van Rhijn stated, but if anything too small. He further compares the absolute magnitudes deduced from the measured parallaxes with those deduced from proper motions. He thus obtains for the K0 giants the mean absolute magnitude 0·8 (two independent discussions give 0·6 and 1·0), while the trigonometrical parallaxes give 0·7, again suggesting that the latter are if anything too small.

It is useful to apply these tests, for the spectroscopic parallaxes would be affected by systematic errors in the trigonometrical ones that were used for calibration of the spectral curves.

Research Items.

Indian Villages in the Eastern United States.—Various writers during the eighteenth century mentioned the Indian tribes in the Upper Missouri Valley, but their accounts are vague, and little was known of these tribes until the transfer of Louisiana to the United States. The condition and structure of their abandoned villages have been examined by Mr. D. I. Bushnell in Bulletin No. 77 of the American Bureau of Ethnology. Natural environment influenced the various types of structure. Thus in the densely timbered country to the north, about the head-waters of the Mississippi and far beyond, the mat- and bark-covered wigwams were developed and employed practically to the exclusion of all other forms of dwelling. But in the plains, and in the regions bordering on the great buffalo ranges, the skin-covered tipis predominated, though other forms were sometimes constructed by the same people. The earth lodges erected by the tribes in the Missouri Valley were the most interesting structures east of the Rocky Mountains, and these at once suggest the rotundas, or great council-houses, once built by the Cherokees and Creeks east of the Mississippi. The discussion of these various types of habitation is most instructive, and, as is the case with other publications of the Bureau, the monograph is fully illustrated by admirable photographs.

Purposive or Mechanical Psychology.—In the *Psychological Review* (Vol. 30, No. 4) Prof. Wm. McDougall gives a very clear and interesting account of the rival theories of purposive and mechanical psychology. Some years ago, in his well-known book, "Body and Mind," he reviewed the position as it stood then from the historical and modern point of view; in this paper he reaffirms his belief in purposive psychology and considers that form of mechanistic psychology which is popular now, namely, that of behavourism. He admits that there is no logical reason why behaviourists should necessarily be mechanists, but shows that actually very many of them are. For certain very limited purposes mechanical psychology may have value as providing a convenient terminology; but as soon as a study of personalities is required, then the student is immediately concerned with energy, persistence, ambition, etc., qualities which the mechanistic psychology cannot explain. If a psychology is required which shall be able to explain the life of man in society or to aid those in mental distress, or to direct education, or to further the problems of ethics, politics, or economics, then that psychology must take into account purposes and motives; mechanical psychology as such can know nothing and teach nothing about human motives.

Nitrogen-fixing Bacteria in Leaf Nodules.—L. A. Boodle, in an interesting note in the *Kew Bulletin* (No. 9, for 1923, p. 346), directs attention to the little-known phenomenon of nodules containing nitrogen-fixing bacteria occurring as a rule upon the leaves of some of the tropical Rubiaceæ. The bacteria occur in the seed, between the embryo and endosperm, so that the seedling is infected on germination. The bacteria then establish themselves in the leaf-buds, in a gummy secretion within the stipular sheath, and from thence enter the young leaves through stomata. The nitrogen-fixing capacity of these bacteria has been experimentally established by von Faber; Rao in India recently confirming this fact. It is interesting to learn that native practice in India and Ceylon values highly the leaves of species of Pavetta and Chomelia, which bear nodules harbouring these bacteria, for use as green manure.

New Plants.—Part iv. of the new volume (148) of Curtis's *Botanical Magazine* contains several plants of especial systematic interest. *Clethra Delavayi*, Franch, belongs to a genus regarded as having Ericoid affinities, although with free petals. Reasons have also been given for placing Clethra with the Theaceæ and Dilleniaceæ among the more primitive Parietales, but Dr. Stapf argues that our respect for the taxonomic value of gamopetaly must make us resist a recent suggestion to bring the Ericaceæ also over to the side of the Theaceæ. *Carmichaelia australis*, R. Br., is a plant belonging to a remarkable genus, almost confined to New Zealand, not before illustrated in this work. Cheeseman terms the genus the most difficult in the New Zealand flora for the systematist; "everything but the pods seems to be in a state of flux." *Rhododendron sinogrande*, Balf. f. et W. W. Smith, was regarded by Sir I. Bailey Balfour as the Chinese representative of the Himalayan *R. grande*, Wall. It is described as having "the finest leaves of any evergreen yet seen in this country." Admiral H. Lynes is quoted for an admirable description of the habitat on the Lake Chad-Nile divide where the brilliantly coloured *Hæmanthus Lynesii*, Stapf, was first discovered. The new species is illustrated from one of the last plants sent in to Kew by the late Mr. Elwes from his garden at Colesborne Park. *Wattakaka sinensis*, Stapf, is a climbing Asclepiad, which has figured under many generic names, but Dr. Stapf agrees with recent systematic reports that the Chinese species must go with its Malayan fellow, *W. volubilis*, into a separate genus, the name for which is derived from the Malayan species. *Echium cœleste*, Stapf, is another endemic species confined to a very restricted area within the Canary Islands. There are already three other endemic species of Echium known from the island of Palma, and one of these, *E. gentianoides*, like the present species, is known only from the mountains above Garafia. *E. cœleste* is perhaps the most beautiful of this striking group of endemics, and may therefore be of interest to horticulturists, as several striking hybrids have already been produced from species of Echium.

Australian Dung Beetles.—In the Records of the South Australian Museum, vol. ii. No. 3, June 1923, are several noteworthy papers on Australian insects. Mr. Arthur M. Lea treats of the dung beetles of the sub-family Coprides, but in comparison with other parts of the world Australia is poor in indigenous species of these insects. This, however, is scarcely surprising considering the dearth of large indigenous mammals. Dung beetles of several kinds have multiplied with the distribution of domestic animals, and many European species have been introduced. Several of the genera are of exceptional interest, especially Macropocopris, species of which live in fur about the anal region of marsupials, and have developed very powerful claws: one species, *M. symbioticus*, has been found in the cloaca of a wallaby.

Praying Insects of Australia.—The Mantidæ or praying insects of Australia are enumerated by Mr. Norman B. Tindale in the Records of the South Australian Museum, vol. ii. No. 3, June 1923. They are evidently abundantly represented. The known Australian species now number 76, including 4 genera and 16 species added by Mr. Tindale. One of the

most interesting forms is *Bolbe maia* sp. nov., which is the smallest known mantis and attains a length of only 8 mm. Mr. Tindale mentions that it came freely to light in a camp, and was so active that it was very difficult to capture; it often seized flies and other insects which had been likewise attracted. Another new mantid, *Parhierodula majuscula*, is probably the largest Australian member of the family, and the female measures 95 mm. long, while the outspread tegmina have an expanse of 113 mm. A third species, *Orthodera ministralis* Fab., seems to occur in all parts of the continent as well as in Tasmania. It exhibits a wide range of variation, which has resulted in an extensive synonymy; notwithstanding its wide distribution, it does not appear to have developed any clearly defined local races, unless the Tasmanian form is to be regarded as coming under that category.

THE EARLY PROBOSCIDEANS.—Much has been written on the genus Moeritherium, which is known from its remains in the Qasr-el-Sagha beds of the Fayûm in Egypt, and was first described by C. W. Andrews of the British Museum. H. Matsumoto (Bull. Amer. Museum Nat. Hist., vol. 48, p. 97, 1923) now reviews the species, with the aid of specimens in the American Museum of Natural History, and concludes that M. Schlasser was not justified in regarding the smaller forms styled *M. gracile* and *M. trigodon* as sexual varieties respectively of *M. lyonsi* and his species *M. andrewsi*. Schlasser retained only the last two names; Matsumoto points out that, even in that case, the name *trigodon* has priority over Schlasser's *andrewsi*. He concludes, however, that all four species are distinct, and he thus keeps the happily named *M. andrewsi* on the list. He regards some early Moeritherium as ancestral to Palæomastodon, with which three of the known species are associated in the Oligocene (or "Upper Eocene") beds. *M. gracile* is known only from the lower series, the Qasr-el-Sagha beds, here styled Middle Eocene. The author supports the views of Andrews, and emphasises the proboscidean characters as against those that have been held by others to be sirenian. He remarks that, while Moeritherium no doubt haunted watery places, its anatomy does not indicate that it was more aquatic than Hippopotamus.

GEOLOGY OF THE WEALD.—The Geological Survey of Great Britain has issued a memoir on "The Concealed Mesozoic Rocks in Kent," by G. W. Lamplugh, F. L. Kitchin, and J. Pringle (E. Stanford, Ltd., 1923; price 7*s*. 6*d*.). A great deal of interesting information is here brought together as to the floor on which the best-studied Cretaceous rocks in Britain rest, and special attention is directed to the comparison now possible of the Kimmeridge Clay of Kent with that of Dorsetshire. In the Proceedings and Transactions of the Croydon Natural History and Scientific Society, vol. 9, pt. 3 (Croydon: Roffey and Clark; price 5*s*., 1923), Mr. C. C. Fagg, president for 1922, treats of the recession of the chalk escarpment in the district south of Croydon, and shows how the dry gaps have been influenced by the lowering of the surface of the Gault. He points out that the River Mole just below Dorking tends to disappear in summer, and how, in no long geological time, it will cease to run through the gap, and will be captured by tributaries of the Wey. Numerous sections illustrate this paper. It is followed by one by Mr. G. T. McKay on meanders, dealing specially with the Mole. The influence of the veteran geologist, Mr. Wm. Whitaker, at Croydon has clearly been fruitful in guiding geological research.

CHEMICAL PORCELAIN.—An article by Dr. G. N. White on "The Manufacture of English Chemical Porcelain" appears in the *Chemical Age* for Sept. 29. The basis of all pottery is china clay, which is a complex, but relatively unstable, substance, for it decomposes at about 600° C., the products of decomposition being alumina and silica. The latter substances unite only at very high temperatures, about 1650° C.; the use of lower temperatures yields a porous product which is useless for chemical ware. Fluxes are added (*e.g.* silica and felspar mixture), so that a vitrified product results, though for chemical ware the amount added must be a minimum. The article is illustrated with photomicrographs, and types of fracture—mechanical and heat—are discussed.

DEFINITIONS OF PHOTOMETRIC QUANTITIES.—The National Illumination Committee of Great Britain has now supplemented the useful work it has already done in connexion with definitions of the chief photometric quantities by a list of symbols denoting luminous flux (F), candle power (J), illumination (E), and brightness (B). Greek letters are also proposed to indicate reflection, absorption, and transmission ratios. The aim has been twofold: (*a*) to unify existing practice, and (*b*) to avoid possible confusion with international electrical symbols. Explanations of the reasons leading to the adoption of these symbols are given in tabular form. Those for luminous flux, illumination, and brightness are already widely adopted. The only notable departure is in the adoption of "J" for candle power—a symbol general in Germany, but not elsewhere. The reason for rejecting "I," which is at present very generally used, is that this symbol is unfortunately already assigned to current in international electrical nomenclature.

CORROSION OF CONDENSER TUBES.—Some of the more important recent results of the investigations conducted for the Corrosion Committee of the Institute of Metals are contained in a paper presented to the North-east Coast Institution of Engineers and Shipbuilders on October 19 by Dr. Bengough, Mr. R. May, and Miss Pirret. Very rapid corrosion of condenser tubes is essentially a recent trouble, and takes the form of smoothly water-worn depressions, extending over several feet of the tube, and mostly in certain positions. Electrolytic protection fails to prevent it. Should a tube survive the first few weeks under the given conditions, attack of this kind is not likely to occur later. The effects are not due to uneven composition of the tubes or to surface imperfections, and laboratory experiments show that the cause is the presence of entangled air in the water, which in modern practice travels with a high velocity. The critical period in the life of a tube is its early life, before a coating of scale has had an opportunity of forming; once this scale has firmly established itself the resistance to corrosion is very greatly increased. Different waters also differ in regard to their power of foaming, those which readily foam being the most corrosive in presence of air. The attack is usually limited to certain parts of the condenser, and when defects are discovered the renewal of tubes should be limited to those parts, as the wholesale re-tubing of the condenser may mean the removal of a large number of perfectly good tubes which have already received their protective coating of scale. High water speeds and high vacua are the modern conditions that have brought about this trouble. It is suggested that the artificial production of a scale on the tubes before putting into use may be found to be practicable.

Scientific Activities in Birmingham.

THE closing days of October have witnessed two highly interesting and important functions in the educational life of Birmingham. The former of these events was the visit of Sir Robert Hadfield on October 30 to the Metallurgical Society of the University of Birmingham to receive the Thomas Turner Gold Medal and to deliver an address on "The History and Progress of Metallurgical Science and its Influence upon Modern Engineering." In presenting the medal the Principal of the University, Mr. C. Grant Robertson, stated that about three years ago a Birmingham manufacturer, desirous of commemorating the valuable work done by Prof. Turner in metallurgy, generously presented a sum of money to the University to found a Thomas Turner gold medal. The donor stated that it was his express wish that the medal should only be awarded to such persons as had rendered eminent service to metallurgy. In Sir Robert Hadfield they had a man who was not only the head of a large firm of world-wide reputation, but one who was also a fellow of the Royal Society, eminently distinguished by his own metallurgical researches. The authorities were perfectly unanimous in deciding that the first award of the medal should be made to him. Mr. Grant Robertson then handed the medal to Sir Robert, who, after expressing his deep appreciation of the honour conferred upon him, delivered his address. More than three tons of exhibits were on view, and the address was illustrated with lantern slides and a series of unique cinematograph pictures. One slide was particularly impressive. It showed Sir Robert's own motor car together with a $4\frac{1}{2}$ inch projectile. It was pointed out that the car, when travelling at the rate of 60 miles per hour, possessed exactly the same energy as the small projectile on leaving the gun with a velocity of 1100 feet per second. The cinematograph pictures were likewise highly instructive. They included, by special permission of the Directors of Artillery and Naval Ordnance respectively, pictures of the loading and firing of a 15-inch gun. This type of gun, which was used largely during the War, weighs 97 tons, is 57 feet in length, and carries a projectile weighing 1910 lb. At full elevation and with a muzzle velocity of 2500 foot seconds, the range is 20 miles.

Sir Robert's address has been printed *in extenso*, and is issued as a beautifully illustrated monograph which repays careful study. An interesting account is given of modern artillery practice, reference being made to the 18-inch naval gun, the largest yet constructed, which weighs 150 tons, but is now prohibited as the result of the Washington Conference. Armour-piercing projectiles, $1\frac{1}{2}$ tons in weight, were made by Messrs. Hadfield for this gun and could be hurled for a distance of 30 miles. Even at this extreme range they could pierce nearly one foot of ordinary steel armour. Attention is directed to the practical difficulty of hardening these projectiles, for a mass of something like 10,000 cubic inches of steel at 900° C. has to be quenched suddenly in a cold bath. This induces internal strains which may continue for weeks or months, leading to rupture during storage, unless suitable treatment is applied.

A considerable portion of the address is devoted to Birmingham itself, and contains a résumé of the lives of its great men, past and present. It is pointed out that our present Prime Minister, the Rt. Hon. Stanley Baldwin, was once a student in the Metallurgical Department of the old Mason College in Edmund Street, under Prof. Turner. So also was the present Chancellor of the Exchequer, the Rt. Hon. Neville Chamberlain, who was that evening unanimously elected an honorary member of the University Metallurgical Society. Dr. F. W. Aston, a Nobel Prizeman, is another old student of the College.

Birmingham is the second city in England, and the fourth city in the Empire, as regards population. In 1700 it contained 15,000 people, a number that had swelled in 1921 to 920,000. With these figures before us it is natural to inquire into the cause of the steady growth of the city. But upon doing so we are at once confronted with a difficulty. Most of our large industrial cities have received help from their geographical position. What does not London owe, for example, to the Thames; Liverpool to the sea; Manchester to her climate; Sheffield to her mineral wealth? But Birmingham has none of these advantages. Situated in the centre of England, one hundred miles from the sea, helped by no large river, supported by no great mineral wealth, it has nevertheless more than managed to hold its own. This is the more striking when we recollect that Dudley, with all its ancient prestige and mineral wealth, is still a small neighbour; whilst Aston, which once was of far greater importance than Birmingham, has now been swallowed up in the extension of this latter city.

Why is this? There have, no doubt, been many contributory causes. Small things ofttimes determine which rivulet, among many, shall ultimately grow into a mighty river. So with cities. In the twelfth century Henry II. granted to Peter de Bermingham the right to hold a weekly market. This much coveted privilege, though long since obsolete, exerted no small influence on the future of the town, by converting it into an important Midland trading centre. In later years Birmingham became popular for its broad-minded policy of religious toleration, which led many worthy persons to take up residence in the town, thereby strengthening its intellectual life and quickening its industrial vitality.

It not infrequently happens that those whom Nature has most richly endowed fail to achieve greatness because their path through life has been too easy. It may well prove that the very lack of natural advantages, so far from being a hindrance, has actually been one of Birmingham's greatest assets, in that it has taught the sons of Birmingham to rely upon themselves. A strong mental calibre has thus been developed together with a spirit of sturdy independence—attributes that have enabled Birmingham to raise itself to a position of eminence within the Empire. A city that can boast an intimate association with Watt, Boulton, Murdoch, Priestley, Bright, Chamberlain, and scores of others known to fame, need not fear the future.

This brings us to the second event of which we write, namely, the opening by Sir Robert Hadfield on October 31 of a new research laboratory and lecture room in the Chemistry Department of the Birmingham Municipal Technical School. The Principal, Dr. W. E. Sumpner, stated that two years ago these rooms were merely attics filled with lumber. They have now been cleared and made habitable by the Education Committee, the equipment being provided out of funds amounting to more than 400*l.* voluntarily subscribed by local firms. This recognition by manufacturers and others of the value of technical education and research is a most encouraging sign of the times. The Rt. Hon. the Lord Mayor, Alderman Sir David Davis, presided, and in his introductory remarks pointed out that the rooms could not have been opened under more auspicious conditions. The Hadfield Works in Sheffield, the home of manganese steel, are a striking example of the efficiency attainable by the co-operation of science and industry, and

no one could speak with more authority on this subject than Sir Robert Hadfield himself.

The new laboratory has been equipped more particularly for research on corrosion and its prevention. For this purpose it is provided with large corrosion tanks of varying design and with other equipment not usually found in a chemical laboratory. At one end is a dark room containing a magnificent micrographic apparatus purchased with the aid of a grant awarded by the Government Grant Committee of the Royal Society to the head of the Chemistry Department in order to enable him and his research students to study the micrography of corrosion.

As Sir Robert wisely pointed out, the object of a school laboratory is different from that of a works laboratory. The latter is designed to turn out material results; the former is primarily intended for training the men, so that when they pass into industry they will know how to tackle their problems along the most approved lines.

As a further inducement to research three prizes for theses have been offered, namely, one each by Sir Robert Hadfield, the Dunlop Rubber Company, and the Mond Nickel Company respectively. It is hoped that manufacturers and students alike will avail themselves to the full of the new facilities. It is only by the closest co-operation between science and industry that we can hope to capture that portion of the world's trade which is so essential to our national existence.

J. N. F.

Aeroplane Performances.

COMPARISON of the "Wren" light plane with recent U.S.A. Navy racing and fighting aeroplanes shows the price of speed in a definite way. The following table gives some of the more significant figures:

Name.	Power.	Speed Range m./s.	Total Mass.	Lifting Surface.
Wren	$4\frac{1}{2}$ kw.	25/12·5 = 2	175 kg.	11 m²
U.S.A. sea-racer	350 kw.	90/34 = 2·6	1000 kg.	13·5 m²
U.S.A. land-racer	350 kw.	112/33 = 3·4	900 kg.	14·5 m²
U.S.A. land-fighter	300 kw.	76/27 = 2·8	1250 kg.	24·5 m²

The racers have less surface than many of the light planes at Lympne, and the bodies are of the same order of length and cross-section, and show the same scrupulous cleanness of line. To pass from the Wren to the racer, about eighty times the power has been concentrated within the limits of an external surface scarcely distinguishable by the layman from similar types of light plane. The speed obtained is about four and a half times greater. Thus the power required is approximately as the cube of the speed.

This rule is even more accurate in comparing the seaplane with the landplane at the fine incidences occurring at the upper limit of their wide speed ranges. It may be inferred, therefore, that the floats cost half the total power available $(90/112)^3$, in spite of some sacrifice of the lower limit of speed (landing speed), by reduction of surface. The essential inferiority of the seaplane is evident.

In the land-fighter, the inclusion of machine-gun equipment and the reduction of the all-important landing speed to 27 m./s. is obtained by roughly doubling the surface, and sacrificing one-third of the racer's speed, equivalent to about two-thirds of the power.

Great range of speed is always an index of very large margin of power, and therefore of high rate of climb, at sea-level, falling off with height and density, and finally of a high "ceiling" or limit of height attainable.

Assuming liberally in the case of the racer that 100 kw. is required for level flying at 40 m./s. near sea-level, this leaves 250 kw. for climbing. Taking the airscrew efficiency as 0·7 and g as 9·81 m./s², this gives an initial climb of $0{\cdot}7 \times 250 \times 1000$ watts/$900 \times 9{\cdot}81$ m.kg.s.$^{-2}$ = 20 m./s. = 1·2 km./min. To calculate the ceiling height with any accuracy much more precise data are required.

The official height record, of 10·75 km. at this date, rests with France, but the same pilot, M. Sadi Lecointe, has since claimed over 11 km. A U.S.A. claim, not officially accepted in the absence of sufficient control, gives an altitude of 12·5 km., which would mark the invasion by man of the heights of the stratosphere.

The Floor of the North Sea.[1]

THE report on the marine deposits of the south part of the North Sea, referred to below, may be characterised as being long overdue, since it is founded on about 600 samples taken by the Marine Biological Association's steamers in 1904–8, when that Society was undertaking the English share of the International investigations. How extraordinarily efficiently that share of the work was done is illustrated by the reports published on the collections and material and in the peculiar discrimination shown in the selection of these samples. It is common knowledge that much of the substance of this report was known to the Admiralty during the War, proving of value in respect to navigation in foggy and other difficult weather. The area treated, the North Sea roughly from the latitude of the Scottish border to the Straits of Dover, is an exceedingly difficult one on account of the complexity of its past geological changes and the variety of its currents, whether produced by wind or other means, acting in a comparatively shallow sea, much broken by banks (especially in its western parts) and intersected by pits and troughs, of which the Dogger Bank, depth 7 fm., and the Silver Pit, 56 fm., may be mentioned.

The samples were taken out of the material collected by a conical dredge with bag dragged along the bottom and thus selected at each haul out of a considerable quantity of deposit. The colour of the sample was carefully noted, and a series of illustrations of representative samples, showing colour and texture, is published; they are a little hard, as is inevitable with all colour-process work as compared with lithography. The estimations of the amounts of the various grades (determined by least diameters of contents) of gravels, of sands, and of silt were done quantitatively, mainly by means of a special levigating apparatus designed by the author of the report under notice. The different grades after drying and weighing were then examined and their mineral and other contents noted. The absence of the organisms of decay from the samples, which were usually of about 2 kg. weight, was interesting, worms being found still alive after 17 months in the bottles. The percentage present of each sized grade in a sample, having been carefully taken, is multiplied by

[1] Ministry of Agriculture and Fisheries, Fishery Investigations. "The Marine Deposits of the Southern North Sea." By J. O. Borley. (H.M.S.O., 15s. 1923.)

the diameter factor of the grade (least diameter in mm.) and divided by 100, so as to determine the "representative number" of the sample.

The advantage in this technique lies in the fact that the numbers increase roughly in accordance with the increased coarseness of texture of the bottom. The whole method shows a great advance in that it eliminates so far as possible human judgment. It only remained to chart the grounds in accordance with these "representative numbers," this being the basal chart, and then in respect to the percentages present of the grades it was desired to consider especially closely. This has been done in a series of twelve singularly informative charts, which are substituted for the interminable text-descriptions of many authors, a most welcome innovation here with little real loss of matter. The basal chart shows a considerable series of very irregular areas, especially numerous and irregular towards the English coast, and the rest represent the kind of analysis of the bottom material such as would be necessary for the understanding of the conditions, currents and other, that produced these areas. The text shows the actual organic and mineral constituents present in each type of ground.

Thus, while the report is eminently useful to the practical fisherman in his navigation in foggy weather and in telling him about the ground on which he is shooting his nets—each kind of ground is correlated with the abundance or rarity of different species of fish—it constitutes the publication of a research of basal importance in respect to the general erosion of the eastern coasts of England. The bottom, while influenced by land material off each estuary, shows the more gradual passage from the stones or coarse gravels of the English coast to the fine silt of the centre and to the continental sands. The causes of this distribution, so far as present knowledge goes, are attractively discussed—attrition, the grade of material kept in motion by different strengths of currents, the correlation of the areas with the currents as known by independent observations of both surface and bottom movements, and so on.

To conclude, this publication is a practical fisheries report and at the same time a research of very great scientific importance, embodying novel methods of treatment of knowledge and suggesting many further lines of research; the Ministry of Agriculture and Fisheries is to be heartily congratulated on its appearance.

J. S. G.

The Physicist in the Textile Industries.[1]

THE development of the textile industries has been one of the greatest factors in civilisation, but it has been said that the great weakness of the cotton industry—and this applies equally to the other textile industries—is that it is not using to the full the immense powers bestowed on this generation by scientific discovery. In the mill, perfection of manipulation seems, at first glance, to have been attained. It may be said that, if such skill can be developed in the past without the aid of the physicist, then there is no need for him, and this, no doubt, is the attitude of some people whose conservatism still holds them members of the "rule of thumb" school. It is impossible not to admire what has been achieved by such methods, but at the same time one cannot help but wonder what advantages might have been gained had the great skill of the operative been united with the insight of a trained scientific mind. For example, if an attempt is made to probe the inner functions of any of the complicated, or simpler, machines, one soon finds how little is really known about the treatment to which the material is being subjected. On inquiry, varieties of explanation are offered, each, no doubt, a carefully weighed opinion, but still, only an opinion. The reason is that many of the investigations that have hitherto been made took place under vaguely defined, and, therefore, unscientific conditions, with the result that other experimenters have held contrary views, and valuable time has been wasted.

Might not the application of scientific methods settle such controversial matters, and possibly in the end lead to improved machines? There is no question of decrying the ability of the skilled operative; his skill based upon years of mill experience can never be attained by a man whose younger years have been spent in training for scientific work. Undoubtedly the duties of scientific workers are complementary to those of the operative. Here lies the opportunity of the physicist—to bring scientific method into the testing rooms, and even into the mill, in order to ensure that tests made upon the various products of the different machines shall be comparable with those obtained at other times, either on the same or similar machines.

[1] Synopsis of a lecture delivered before the Institute of Physics on October 22 by Dr. A. E. Oxley.

The textile industries offer an almost entirely unexplored and unlimited field for the research physicist, and it is not a question of searching for a problem worthy of investigation, but one of selecting, from the great number of attractive problems presented, a few which shall form the most trustworthy basis on which to build a secure foundation for the development of a progressive research programme. It should be remembered that physical research in the textile world is by no means in such an advanced state as it is in the metallurgical world. Although in the textile industries many of the research problems are of a physical nature, and all have a physical aspect, the number of physicists engaged is only about twenty. A brigade of trained physicists would be more in proportion to the problems urgently awaiting solution. It is safe to say that there is no other industry so much in need of co-operation with the physicist as is the great textile group.

There is one outstanding factor which must be brought to the notice of the physicist contemplating textile research, and this applies to textile materials in general. The material he has to investigate is generally of a most disturbing character on account of its variability. The result is that a very careful selection or sampling of the test specimens must be made, and in many cases very laborious series of tests are needed before a result representative of the bulk, which is the only material recognised by the manufacturer, can be obtained. This fact differentiates rather sharply the physicist of textile research from the physicist in other industries.

Slides were shown by the lecturer to illustrate the types of research on which the textile physicist is engaged. These included investigations on (1) rigidity of the single fibre, a property of fundamental importance in spinning; (2) sorting of samples (*a*) to examine the various fibre lengths in pure cottons or mixings, and (*b*) to detect what damage, if any, is caused to the fibres by the different machines; (3) regularity of threads, a property of great importance in the production of threads for weaving fabrics of fine structure; (4) oscillation stresses on threads such as are met with in weaving; and (5) the measurement of the lustre in finished threads and fabrics and the relation of lustre to doubling twist.

University and Educational Intelligence.

BELFAST.—A letter has been received by the Senate of the Queen's University intimating that the late Hugh Wisnom, of Larne, directed his trustees to invest a sum of 1000*l*. for the foundation of an annual scholarship in the University to be called the "Hugh Wisnom Scholarship," to be awarded in such manner as the governing body shall decide for the encouragement of scientific research.

BIRMINGHAM.—The first award of the Thomas Turner gold medal was made on October 30 at a meeting of the Birmingham University Metallurgical Society, when the Principal (Mr. C. Grant Robertson) presented the medal to Sir Robert Hadfield, Bart., in recognition of his distinguished contributions to the metallurgy of steel. The medal is the outcome of a gift of 525*l*. by a Birmingham manufacturer who desired to perpetuate the memory of the work done by Prof. T. Turner in the metallurgy of iron. The money was invested and is held by trustees for the provision of a gold medal, to be called the Thomas Turner gold medal, which is to be awarded from time to time to distinguished metallurgists. A portion of the fund is applied to the award of a bronze medal and a prize of books to a student to be selected annually from one of the metallurgical schools of the district. The obverse of this medal bears the profile of Prof. Turner and on the reverse is the well-known diagram published by him in 1885 showing the relation between silicon content and tensile strength of iron.

BRISTOL.—For the new degree of Bachelor of Agriculture, a curriculum extending over five years has been prescribed—two in the University, two in the recently reopened Royal College of Agriculture, Cirencester, and one in a selected farm.

CAMBRIDGE.—Mr. H. H. Thomas, Downing College, has been appointed University lecturer in botany.

A grant of 100*l*. has been made from the Balfour Fund to Mr. Cyril Crossland, Clare College, in aid of his researches into the biology of the coral reefs and banks of the South Pacific.

The Regius Professor of Physic announces a short series of lectures on the history of medicine. The lectures this term will be on November 13 and 16 at 5 P.M., on "The Hippocratean Period" and "The Alexandrian Period" respectively.

LONDON.—A course of two free public lectures on "Problems of Variation" will be given by Dr. J. W. Heslop Harrison in the department of zoology, Imperial College of Science and Technology, at 5.15 on Thursday and Friday, November 22 and 23.

THE following scholarships for 1923–24 have been awarded by the Institution of Electrical Engineers: Salomons scholarship (value 50*l*.), to Mr. James Linton (Heriot-Watt College, Edinburgh); David Hughes scholarships (value 50*l*. each), to Mr. R. MacWhirter (Royal Technical College, Glasgow), and to Mr. R. E. Banks (University, Birmingham).

MR. E. S. ELDRIDGE is the first student to pass through the Imperial College of Tropical Agriculture at Trinidad and to secure an appointment in the Colonies. He left on October 25 to take up the position of farm manager in charge of the Empire Cotton Growing Corporation's Cotton Experiment Station in Nyasaland.

PRINTING may now be taken as one of two principal subjects of study for the degree of Bachelor of Commerce of the University of Leeds, and in this connexion the Leeds Central Technical School Printing Department has been affiliated to the University.

FROM the Technical College, Bradford, we have received an illustrated prospectus for 1923–24. The College provides, in addition to part-time evening and day courses, full-time courses covering from one to four years in textile industries, chemistry, dyeing, engineering, physics, and, exceptionally, in biology. The teaching body includes 42 whole-time lecturers. Special courses in advanced study and in training in the methods of research are available, a special physical chemistry laboratory having been recently equipped for research purposes and additional accommodation provided for research in dyeing.

THE annual meeting of the Science Masters' Association will be held on January 3-5, 1924, in the buildings belonging to the Household and Social Science Department, King's College for Women, situated in Campden Hill Road, W., where, in addition to suitable accommodation for lectures, exhibits, etc., there will be residential quarters for about eighty members attending the meeting. The Association has accepted the invitation to participate in a joint conference with the members of the Royal Meteorological Society, and of the Geographical Association, to be held at Birkbeck College, London, on Thursday, January 3. The conference will discuss the present state of knowledge of meteorology and the bearing of the science on cognate school subjects.

AMONGST prospectuses issued by University College, London, for 1923–24, is one of twenty-seven pages, devoted to post-graduation courses of lectures and practical work, including special courses by the new professor of chemical engineering and six courses in the recently established department of "History and Method of Science," by Dr. Charles Singer (general, biological, and anatomical), Prof. Filon (astronomy), and Mr. W. J. Perry (anthropology). In the Rockefeller anatomy building is to be installed, in a room for cinematographic study of animal movements, equipment designed in the Marey Institute of Paris capable of taking 300 photographs a second of moving objects. Post-graduation and research students of the college in 1922–23 numbered 431, including 133 from outside Great Britain.

THE teaching of civics is receiving much attention at present in America. Prof. Edgar Dawson, of Hunter College, New York, has contributed to the Biennial Survey of Education, 1920–22, a chapter (published separately as Bulletin, 1923, No. 23) on "The Social Studies in Civic Education," in which particulars are given of some developments in this field. The new Pennsylvania State course in the social studies aims at giving effect to a conception of "civics" as training in practical good citizenship and, as such, a vital part of the schooling of every child, and even "the only justification of the tax-supported public-school system." It begins with the first year of school life and continues without a break to the end of the twelfth year, being adapted, grade by grade, to the various psychological stages through which the normal child passes. The last three years of the course are primarily intended to train pupils "to investigate, to reason, to compare, to judge." To neglect any longer the provision of specific training in the problems of American democracy, the solution of which will soon be in the hands of the secondary school pupils of to-day, is, in the opinion of the State department, to render a social cataclysm inevitable.

Societies and Academies.

LONDON.

Royal Society, November 1.—E. G. T. **Liddell** and Sir Charles **Sherrington**: A comparison between certain features of the spinal flexor reflex and of the decerebrate extensor reflex respectively. Comparison of the tetani of the knee flexor, evolved by motor nerve stimulation and by reflex excitation, shows somewhat close resemblance between them. A constant difference is the presence of after-discharge in the latter. A further difference frequently found is, the myograph records being isometric for both, a steeper ascent and sharper ascent-plateau turn for the reflex. The reflex tetanus, like the "motor-nerve" tetanus, appears to engage from its very beginning the full quota of the motoneurones that it will at any time under its further continuance engage. The steeper ascent in the reflex is due to after-discharge setting in early, so that some of the motoneurones activated by the reflex cannot respond to the immediately succeeding series of stimuli. Intensity and not duration in the external stimulus is therefore the sole arbiter of the intensity of the reflex tetanus. Similar comparison of the crossed reflex of the knee extensor with the "motor-nerve" tetani of that muscle shows that the reflex tetanus develops much the more slowly, and that the ratio between the tension developed by the reflex contraction to a single shock and that to a serial stimulus is much less than under "motor-nerve" stimulation. The reflex at its outset appears to activate only a small fraction of the quota of motoneurones that it will gradually bring into activity.—J. **Barcroft** and H. **Barcroft**: The blood pigment of Arenicola. The blood pigment of *Arenicola Marina* differs from the hæmoglobin of human blood in certain respects. The α band of the oxy-hæmoglobin is situated 18 Å.U. nearer the violet and the α band of the carbon monoxide hæmoglobin is situated 11 Å.U. nearer the violet than the corresponding human band. The dissociation curves show a greater affinity for both oxygen and carbon monoxide than those of human blood. The affinity for carbon monoxide is about 70 times that for oxygen, as compared with 250 in man and 140 in the mouse. The possibility of a relationship between the position of the bands and the affinity of the pigment for gas is discussed. The main unloading of oxygen from the pigment of Arenicola would appear to be between 1 and 3 mm. pressure. The mean oxygen capacity of the hæmoglobin per gram of Arenicola is about 0·01-0·013 c.c. A comparison between the oxygen capacity of the pigment and the total oxygen consumption of the worm shows that the pigment holds sufficient oxygen to supply the animal for 1-2 hours, and probably acts as a reserve to tide it over the period at low-water when its hole is closed.—T. **Deighton**: The basal metabolism of a growing pig. The basal metabolism of a pig has been measured at various ages from seventy-five days upwards, and it has been shown that in the pig, as in human beings, the metabolism per unit area is greatest in mid-youth. This increase of metabolism in youth seems to be directly ascribable to growth. Metabolism after the ingestion of food reaches a maximum after five hours and then declines. The rationing of pigs for maintenance and growth is discussed, and it is concluded that the curve of rationing for growth and maintenance, without fattening, cannot possibly be a two-thirds power curve.

Physical Society, June 22.—Dr. Alexander Russell in the chair.—F. **Horton**: The excitation and ionisation potentials of gases and vapours. The study of ionisation potentials dates back to the discovery of the phenomenon of the ionisation of gases by collision, but the theoretical importance of a knowledge of the least difference of potential through which an electron must fall in order to acquire sufficient energy to ionise a gaseous atom or molecule on collision with it has greatly increased since the propounding by Bohr of his theory of atomic structure. Bohr's theory predicted the possibility of an atom being excited to emit radiation by the impact of an electron having energy in excess of a definite minimum amount—an amount corresponding to an "excitation" potential less than that required for ionisation. The experimental methods of investigation may be divided into two classes: (1) Those depending on the detection of the loss of energy by the colliding electron; (2) those depending on the detection of the radiation or ionisation resulting from the collisions.

Royal Meteorological Society, October 17.—Dr. C. Chree, president, in the chair.—Sir Napier **Shaw** and D. **Brunt**: Towards a basis of meteorological theory: thirty-nine articles of condition for the middle atmosphere. The propositions refer to the "middle layers" of the atmosphere, or those from 4 to 8 kilometres above mean sea-level; that is, the region lying above the effects of the friction of the earth's surface and below the stratosphere. Owing to the normal increase of potential temperature with height, the middle atmosphere is possessed of resilience and may be regarded as made up of separate aerospheres or horizontal layers which are thermally and therefore dynamically distinct. Air will not pass from one aerosphere to another without some internal source of energy, but there is no resilience for horizontal motion within an aerosphere. That a wide field for discussion is opened is evident from quotation of No. 6 as an example: "The chief effective cause of the general circulation between the equator and the poles and the correlated circulation round the poles is the cooling of the slopes and plateaux of high land in the polar regions."

Royal Microscopical Society, October 17.—Prof. F. J. Cheshire, president, in the chair.—W. F. **Charles**: Peculiarities in the development of the ant's foot. On the inside of the lower palate of the snapdragon, and surrounding the base of the stamens, there is a series of glandular hairs containing a viscous fluid; but these capitate hairs cannot be ruptured by the ordinary claws of the insect. Within the pulvillus of each foot of ants found on snapdragon there appears to be a minute pair of forcep-like claws, developed expressly to enable the insect to grasp and pull itself along hairy surfaces. These claws were sufficiently sharp to puncture certain minute depressions upon the surface of the glandular hairs, releasing the viscous fluid and entangling the ant. The depressions on the hairs, which are covered with one epidermis only, appear to facilitate the rupture.—M. T. **Denne**: A new variable light screen for use with the microscope. The instrument consists of a cylindrical cell provided with an end plate of glass, and a piston sliding within it bearing a second glass plate arranged so that adjustment with respect to the fixed plate may be effected by a high-pitch screw and nut combined with worm gearing. A coloured or neutral-tinted fluid can be introduced between the plates. With stained preparations, the screen permits the gradual intensification of the image of certain elements at the expense of others; with unstained preparations, it gives increased visibility, while dark ground effects are distinctly improved. The range given is from total transmission to nearly extinction of the incident beam.

Industrial Applications Section, October 24.—Prof. F. J. Cheshire, president, in the chair.—Marie C. **Stopes**: The microscopy of recent coal research. Early workers like Dawson and Huxley tended to treat "coal" as if it were a uniform substance. Hence arose disputes, and apparent contradictions, one demonstrating that "coal" was made of spores, others saying that "coal" was made of wood, others of bark. Recent work has shown differences between the finer bands even in the same lump of coal, where only a few millimetres apart one zone may show a preponderance of spores, another a preponderance of leaf or stem tissue, and another a uniform glue-like texture. The four main types composing bituminous coal are fusain, durain, clarain, and vitrain. Prof. Seyler has shown similar zones in anthracite by an opaque method of examination by reflected light.

Zoological Society, October 23.—Dr. A. Smith Woodward, vice-president, in the chair.—E. A. **Spaul**: Experiments on acceleration of metamorphoses of frog-tadpoles by injection of anterior-lobe pituitary-gland extract and iodine.—A. **Subba Rau** and P. H. **Johnson**: Observations on the development of the sympathetic nervous system and suprarenal bodies in the sparrow.—H. C. **Abraham**: A new spider of the genus Liphistius from the Malay Peninsula, and some observations on its habits.—Mr. A. **Smith**: A review of the lizards of the genus Tropidophorus on the Asiatic mainland.—J. G. H. **Frew**: On the larval anatomy of the gout-fly (*Chlorops taeniopus* Meig.) and two related acalyptrate muscids, with notes on their winter host-plants.—A. **Loveridge**: (1) Notes on mammals collected in Tanganyika Territory, 1920–1923. (2) A list of the lizards of British East Africa (Uganda, Kenya Colony, Tanganyika Territory, and Zanzibar), with keys for the diagnosis of the species.

EDINBURGH.

Royal Society, October 22.—F. O. **Bower**: Remarks on the present outlook on descent. At the moment we seem to have arrived at a phase of negation in respect of the achievements of phyletic morphology. So far from presenting a tree with a single trunk, the results of comparison offer us what appears little better than a bundle of sticks. The prospects appear depressing to young aspirants, and it is said that phyletic morphology leaves them cold. But this depends very largely upon the mode of presentment. How, then, are we to proceed in inquiry as to the origin of living things? Surely by a continued study of morphology in its broadest sense. Mr. Tansley, in his address to the British Association at Liverpool, advocated the study of "process of development," that is, physiological inquiry: but he rightly recognises how "process and structure continually act and interact." Structure may be held as the record of process. Any school based primarily on "process" and with "record" relegated to the background might turn out good statisticians, but it would probably fail in converting them into historians. Provided, however, that the study of "process" and "record," that is, of physiology and morphology, be co-ordinated, all may be well with the future of phyletic morphology.

MANCHESTER.

Literary and Philosophical Society, October 23.—H. **Clay**: The economic aspect of the Ruhr problem. The Ruhr is the richest coalfield in Western and Central Europe. Before the War, its output was 60 per cent. of the coal and 80 per cent. of the coke output of Germany; it was the chief centre of the steel industry and the chief source of the coal-tar used by the dye industry and of sulphate of ammonia used in agriculture. Territorial changes under the Treaty have enhanced the relative importance of the Ruhr in Germany's national economy. The occupation by the French, coupled with passive resistance, rapidly reduced the economic activity of the Ruhr. Reparations deliveries of coal almost ceased, and 46 French blast-furnaces out of 116 were damped down between January and April. The Ruhr population was maintained by subsidies from Berlin. The dislocation of industry caused by the separation of the Ruhr and the demoralisation caused by the depreciation of the currency have steadily reduced the efficiency of German industry, until it can no longer produce at world-prices. Unemployment is growing; it is certain to increase if the Berlin (or any other) Government succeeds in floating a new, stable currency and checking inflation. It is unlikely that any German Government will be in a position to pay any reparations, so far ahead as it is practicable to look. The French are unlikely to gain any economic benefit from their occupation of the Ruhr. The policy, so far as its objects were economic, has paid insufficient regard to two fundamental truths; first, that the wealth of a country is not a stock of goods that can be seized, but the output of an organisation that continues only so long as the organisation functions; and, second, that the direction and activity of the industrial organisation responds only very slowly and incompletely to political dictation.

SHEFFIELD.

Society of Glass Technology, October 17.—A. R. **Sheen** and W. E. S. **Turner**: The effect of titania on the properties of glass. Batches were calculated on the basis of the formula, $6SiO_2$, xNa_2O, $yTiO_2$, where $x+y=2$. The first six members of this series gave glasses readily; *i.e.* where the value of y varied from 0·1 to 0·6. Above 0·8 (*i.e.* 13 per cent. TiO_2) it was found difficult to melt the glass at 1400° C. When compared with the corresponding lime and magnesia glasses, the titania-containing glasses had somewhat lower annealing temperatures, durability similar to that of magnesia glasses, and thermal expansion slightly less than that of lime glasses. Heat-resisting properties were also indicated.—A. **Cousen**: The estimation of selenium in glass. Twenty grams of finely powdered glass were dissolved slowly in hydrofluoric acid and, after standing in the cold, the products of decomposition, with the exception of selenium, were dissolved by pouring into excess of boiling water. The selenium itself was filtered off on a filter pulp pad in a Gooch crucible. From the pad the selenium was removed by treating with a dilute chlorine solution (about 1/300 N). To the filtered solution was added 1 c.c. of 5 per cent. gum arabic and 5 c.c. of ½ per cent. phenyl hydrazine hydrochloride, the whole being made up to 50 c.c. Colloidal selenium was obtained, a yellow colour slowly developing. After half an hour this colour was matched against a standard solution of sodium selenite similarly treated.

PARIS.

Academy of Sciences, October 15.—M. Albin Haller in the chair.—A. **Lacroix**: The notion of doliomorph type in lithology. The term "doliomorph" is applied to lithologic types, which, from the chemical point of view, do not correspond with their mineralogical composition. According to the usual mode of expression, quartziferous rocks, rocks with free silica,

acid rocks are regarded as synonymous. It is shown that this equivalence is not always legitimate. In the new classification, doliomorph types are not classed with rocks of the same qualitative mineralogical composition, but with those of the same chemical composition, with some of which they are heteromorphs.—Jean **Perrin**: Radiochemistry and fluorescence. Results of measurements on the disappearance of "new methylene blue" under the action of light, completing the theory proposed in an earlier communication (*C.r.*, 1923, p. 612).—L. **Joubin**: The meeting of the International Council for the Exploration of the Sea, held at Paris. An account of the work done by the committees.—V. **Grignard**, J. Dœuvre, and R. **Escourrou**: The constitution of natural methylheptenone. The ketone exists in two isomeric forms, and this has given rise to some uncertainty regarding its constitution. The authors have applied the method of oxidation by ozone and have estimated the oxidation products, formaldehyde (with formic acid and carbon dioxide) characterising the α-form, acetone the β-form. Methylheptenones from four different sources were examined by this method, and it was shown that the natural ketone is a mixture of both forms; the α-form is in the smaller proportion, about 25 per cent.—Ervand **Kogbetliantz**: The unicity of trigonometrical series.—F. H. **van den Dungen**: Integral equations, with several parameters and their technical applications.—N. Vasilesco **Karpen**: The mechanism of hovering flight.—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the third quarter of 1923. Owing to bad weather, observations were possible on only sixty-two days during the quarter. The usual tabular summary is given.—Mlle. **St. Maracineanu**: A method of measurement suitable for a strong radiation. The method described is applied to the cases of polonium and actinium.—Claude **Bonnier**: Aqueous solutions of ammonium bicarbonate. When ammonium bicarbonate is dissolved in water in a closed vessel, there is evolution of gas, and pressure is set up. In the present note the influence of concentration of the solution and of the ratio of the volumes of the liquid and gas phases on the pressure is studied, and the experimental results expressed in the form of curves.—M. **Bourguel**: The preparation of true acetylene hydrocarbons by sodium amide, starting with 2-3-dibrompropylene. Hexine and cyclohexylpropine. The dibrompropylene, $CH_2Br . CBr : CH_2$ (prepared from allyl bromide), is treated with a magnesium alkyl bromide, RMgBr, under conditions exactly defined, giving the bromide, $R . CH_2 . CBr : CH_2$, and hydrogen bromide is removed from this by treatment with sodium amide. The hydrocarbons obtained are true acetylenes, and the method is a general one.—Raymond **Delaby**: The catalytic dehydration of ethylglycerol.—J. F. **Durand**: Double decompositions, in aqueous solutions, between metallic acetylides and salts.—Jean **Bordas**: A cause of error in the Iodlbauer method for the estimation of total nitrogen. The presence of tannins in substances analysed by this method causes errors due to loss of nitrous fumes.—P. **Gaubert**: The planes of Grandjean.—Emile **Belot**: A form of latent vulcanism in connexion with earthquakes and tidal waves. The experimental reproduction of a tidal wave.—E. **Rothé**: The earthquakes observed in France in the course of the year 1922. Fourteen shocks were felt during the year, a number much higher than the average. Details are given of each.—René **Souèges**: The embryogeny of the Joncaceæ. The development of the embryo in *Luzula Forsteri*.—V. **Lubimenko**: The influence of leaf wounds on the production of dry substance in green plants.—E. **Lesné** and M. **Vagliano**: The differentiation of vitamin A and the factor preventing rickets.—F. **Vincens**: A disease of the bee (muscardine) due to *Beauveria Bassiana* produced experimentally in bees. This fungus, when present in the food, is readily communicated to bees, causing death within six days.—E. **Roubaud** and J. **Descazeaux**: A bacterial agent pathogenic to the common fly, *Bacterium delendæ-muscæ*. This new coccobacillus was isolated from a spontaneous infection which occurred during the study of *Stomoxys calcitrans*. Details are given of its morphology and culture. The domestic fly is very resistant to bacterial infection, and the fact that it is attacked and killed by the new type is of great interest.—A. T. **Salimbeni** and Y. **Kermorgant**: A new spirochæte met with in the blood of patients suffering from measles.—Fernand **Wyss**: Variation in the morphology and acido-resistance of the human tubercle bacillus under the influence of a saponine.

Official Publications Received.

Memoirs of the Department of Agriculture in India. Botanical Series Vol. 12, No. 2. 1: History of the Operations against Bud-rot of Palms in South India; 2: Inoculation Experiments with *Phytophthora palmivora* Butl., on *Borassus flabellifer* Linn., and *Cocos nucifera* Linn. By W. McRae. Pp. iv+21-70. Botanical Series, Vol. 12, No. 3: Studies in Inheritance in Cotton, I. History of a Cross between *Gossypium herbaceum* and *Gossypium neglectum*. By G. L. Kottur. Pp. iv+71-133. (Calcutta: Thacker, Spink and Co.; London: W. Thacker and Co.) 1.4 rupees; 2*s*., each.

Diary of Societies.

MONDAY, NOVEMBER 12.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—Discussion of two papers on Isostasy: Doubts on Terrestrial Isostasy, Prof. A. Alessio; Abnormal Densities in the Earth's Crust disclosed by Analysis of Geodetic Data, W. Bowie.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—Prof. T. P. Nunn: The Philosophy of Gentile.

ROYAL SOCIETY OF ARTS, at 8.—S. H. Davies: The Cultivation of Cocoa in British Tropical Colonies. (Cantor Lecture.)

FARADAY SOCIETY (at Chemical Society), at 8.—A. J. Allmand and A. N. Campbell: The Electrodeposition of Manganese.—S. Glasstone: The Cathodic Behaviour of Alloys. Part I. Iron-Nickel Alloys.—A. L. Norbury: The Volumes occupied by the Solute Atoms in Certain Metallic Solid Solutions and their Consequent Hardening Effects.—J. B. Firth and F. S. Watson: The Catalytic Decomposition of Hydrogen Peroxide Solution by Blood Charcoal.—E. E. Walker: The Properties of Powders. Part VIII. The Influence of the Velocity of Compression on the Apparent Compressibility of Powders.—L. Anderson: (*a*) An Investigation of Smoluchowski's Equation as applied to the Coagulation of Gold Hydrosol; (*b*) The Effect of Sucrose on the Rate of Coagulation of a Colloid by an Electrolyte.—H. H. Paine and G. T. R. Evans: A Method of measuring the Rate of Coagulation of Colloidal Solutions over Wide Ranges.—J. A. V. Butler: Studies in Heterogeneous Equilibrium. Part I.

ROYAL SOCIETY OF MEDICINE (Tropical Diseases and Parasitology Section), at 8.30.—Prof. L. S. Dudgeon: Presidential Address.—Dr. E. C. Faust: Some Biological and Practical Aspects of Schistosomiasis in China.—Miss G. Le Bas: The employment of Fasciola Hepatica as a substitute for infected Snails' Liver for the Fairley reaction in Bilharziasis.

TUESDAY, NOVEMBER 13.

INSTITUTE OF HYGIENE, at 3.30.—Dr. A. M. Hewat: Pure Food Supplies.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—A. Millar: Galician-Canadian Pole Tool Fishing Methods.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—Adjourned Discussion on Paper by H. J. Young and E. Wood, on Cast Iron for Marine Engine Castings from the Metallurgical and Engineering Points of View.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—A. C. Banfield: Some Interesting Optical Munitions from the Mechanical Point of View.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—T. M. Offord: A Talk on Spiders.—J. Wilson: Report on Proceedings of the British Association.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—Reports on Progress during the Vacation and Developments in Lamps and Lighting Appliances.

WEDNESDAY, NOVEMBER 14.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Institution of Mechanical Engineers), at 6.30.—L. Murphy: The Misuse of the Internal Combustion Engine and Suggestions for its more efficient application.

INSTITUTION OF CHEMICAL ENGINEERS (at Engineers' Club, Coventry Street), at 7.30.—M. B. Donald and R. D. Hunneman: A Study of the Conditions of Constant Rate of Flow in Filter Presses.—M. B. Donald and C. W. Tyson: A Study of the Absorption Tower.

ROYAL SOCIETY OF ARTS, at 8.—E. Belin: The Electric Transmission and Reproduction of Writing, Designs and Photographs without Wires.

THURSDAY, NOVEMBER 15.

ROYAL SOCIETY, at 4.30.—Sir William Bragg and Prof. G. T. Morgan: Crystal Structure and Chemical Constitution of Basic Beryllium Acetate and Propionate.—G. I. Taylor: Experiments on the Motion of Solid Bodies in Rotating Fluids.—L. C. Jackson: Investigations on Paramagnetism at Low Temperatures.—L. C. Jackson and Prof. H. Kamerlingh Onnes: The Magnetic Properties of Some Paramagnetic Double Sulphates at Low Temperatures.—H. H. Potter: Some Experiments on the Proportionality of Mass and Weight.—*To be read in title only*:—Lord Rayleigh: Further Studies on the Glow of Phosphorus and its Extinction by Moist Oxygen.—Prof. H. A. Wilson: An Experiment on the Origin of the Earth's Magnetic Field.—Dr. H. Robinson: The Secondary Corpuscular Rays produced by Homogeneous X-Rays.—Lt.-Col. J. W. Gifford, with an Introduction by Prof. T. M. Lowry: Some Refractive Indices of Benzene and Cyclohexane.—J. A. V. Butler: Note on the Significance of the Electrode Potential.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—H. R. Ricardo: The Thermodynamics of Aircraft Engines.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.

CHEMICAL SOCIETY, at 8.—

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W. 1), at 8.15.—Preceded by a Demonstration at 7.45 of various Spirochætes.—Dr. J. Gilks: Yaws in Kenya Colony.

FRIDAY, NOVEMBER 16.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—W. J. Kearton: The Possibilities of Mercury as a Working Substance for Binary Fluid Turbines.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. V. Lyle: Realism and Reality.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—Annual General Meeting.

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Chemical Industry Club, 2 Whitehall Court), at 8.—Prof. J. W. Hinchley: A New Source of Potash, and its Industrial Exploitation.

PUBLIC LECTURES.

SATURDAY, NOVEMBER 10.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. H. S. Harrison: Fashion amongst Savages.

TUESDAY, NOVEMBER 13.

WESTFIELD COLLEGE, at 5.15.—Mrs. Tufnell: A Glimpse of Czechoslovakia.

UNIVERSITY COLLEGE, at 5.30.—W. J. Perry: The Aims of Anthropology.

WEDNESDAY, NOVEMBER 14.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—W. B. Smith: The Extravagance of a Smoke-polluted Atmosphere.

UNIVERSITY COLLEGE, at 5.30.—Sir Jagadis C. Bose: The Physiology of Photosynthesis.

THURSDAY, NOVEMBER 15.

LONDON SCHOOL OF ECONOMICS, at 5.30.—F. Pick: The Problem of London Traffic: The Objects and Effects of Traffic Control.

FRIDAY, NOVEMBER 16.

IMPERIAL INSTITUTE, at 5.30.—E. Audra: France and Europe. (League of Nations Union Lecture.)

KING'S COLLEGE, LONDON, at 5.30.—C. E. M. Joad: The Philosophical Background of Music and Poetry: The Function of Music.

ROYAL SOCIETY OF ARTS, at 8.—Major H. Barnes: Hygiene and Architecture: Preventive Hygiene—Health and the Building. (Chadwick Lecture.)

SATURDAY, NOVEMBER 17.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—G. Morris: The Prehistoric Survey of Selborne.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—S. H. Warren: The Cave-Paintings of Stone Age Man in Europe.

NATURE

Small-pox and Vaccination.[1]

THERE is something refreshingly interesting in the new practice of arranging for the education of our legislators by means of addresses by experts on subjects in which Parliament is concerned, and Dr. McVail's recent address may be regarded as an admirable example of good that may thus be achieved.

Small-pox has, however, more than a practical interest. Next perhaps to influenza it is a disease the epidemiology of which has more scientific interest than that of any other disease; and it is unique in being a disease in which pandemic outbreaks,—invading mankind at irregular intervals in an unexplained manner,—can be entirely and have been largely controlled by vaccination and by the public health measures which circumscribe the action of the virus of small-pox.

Small-pox furthermore is a disease which in recent years, and probably also in the past and even in the pre-vaccination period, has prevailed as two different varieties. One no physician could cure, and one no malapraxis could render fatal to the patient. Thus, in ten cities in the United States, of every 100 persons attacked by small-pox in 1922, 28·4 died, whereas in 1920 the fatality rate in the same cities was only 0·2 per cent. Evidently we are dealing in this experience with two diseases or with two definite mutations of the same disease. That the second is the right explanation is shown by the fact that vaccination protects against the mild as well as against the severe small-pox. In recent years our knowledge of the milder variety of small-pox has greatly increased. It has prevailed widely throughout America, spreading from the Southern Atlantic across to the Pacific. It has invaded Great Britain, and the recent mild outbreak of small-pox in Gloucester and the Midlands belongs to this type.

The mild character of the small-pox in unvaccinated persons in the recent outbreak has raised doubts in some minds as to the necessity for vaccination; but the following facts show the fallacy of this view. First, vaccination protects against the mild as against the severe small-pox. Secondly, there is a difference in degree of severity of attack,—on a lower grade than with the more serious type of disease,—of vaccinated and unvaccinated respectively; and thirdly, although details of current outbreaks are not yet available, it will doubtless be found that, as in the mild outbreaks of a few years ago, unvaccinated are attacked at a much earlier age than the vaccinated.

Nevertheless, if it could be certified that all subsequent outbreaks of small-pox would be of this unusual

[1] *The Fight against Disease.* Smallpox and Vaccination, by Dr. John C. McVail. An Address to Members of the House of Commons in Committee Room No. 14, July 25, 1923. The Minister of Health in the chair. (London: Macmillan and Co., Ltd.) Price 6*d.*

mild type, the necessity for vaccination would be less urgent than it now is. It might be limited to persons exposed to actual infection, or living in the neighbourhood of outbreaks. No such assurance can be given. In New York, both types of small-pox have been known to prevail at the same time. Our knowledge of the causation of variations in type of disease and of the correlative changes in virulence of virus and in fatality of attack is almost nil; and in practice we must be guided by the experience of the past, which shows that Great Britain is liable to be invaded at intervals not only with a relatively innocent type of small-pox coming from the west, but also with a virulent type, hailing from Asia and Africa. We cannot afford to relax our sanitary precautions against both types of the disease, nor can we afford to neglect the artificial immunity against attack which vaccination affords.

Whether in the future the secrets of the origin of the milder type of small-pox will be revealed, or whether it may be practicable to isolate the virus of small-pox or of this virus as organically modified in vaccine lymph, and afford a method of vaccination on a completely scientific basis, one cannot prophesy; but meanwhile the preventive measures already in our hands must be utilised to their fullest extent, and these enable us to control with absolute certainty the epidemic course of small-pox in its intermittent raids on mankind. Of no other disease can this be said with equal certainty, except in regard to certain tropical diseases, and to such water-borne diseases as typhoid fever and cholera. In a few years we may find that the same confident statement can be made in respect of diphtheria, if parents can be educated to realise the practicability of testing their children's susceptibility to this disease by what is known as the Schick test, and to appreciate the equal practicability of securing artificial immunity by means of toxin-antitoxin.

Meanwhile we hope that Dr. McVail's pamphlet will receive wide circulation. It establishes very clearly and succinctly the propositions which it sets out to prove, namely, that small-pox is worth preventing, that it can be prevented by vaccination, that it cannot be prevented without vaccination, and that properly conducted vaccination is very safe.

A National Education Week.

THE institution of a national "Education Week" has been officially blessed by the new President of the United States in an impressive Proclamation in which, after reciting the benefits of education, especially adult education, Mr. Coolidge declares an annual observance of Education Week to be desirable "in order that the people may think on these things." He proclaims the week beginning November 18 as the Education Week for 1923, and recommends that State and local authorities co-operate with the civic and religious bodies to secure its most general and helpful observance.

Last year, President Harding and 42 State Governors issued proclamations or statements on the subject, and the week was said to have been a gigantic success. It was estimated that the campaign reached 50 million people, including 20 million in motion-picture houses. It is probably due largely to the enthusiasm aroused by these annual campaigns that the membership of "parent-teacher" associations increased in two years from 189,000 to 500,000. Reciprocally the associations contribute enormously to the success of the Education Weeks. Without some such machinery the effervescence of the Education Week might subside without leaving any permanent beneficial results. The efficacy of this kind of propaganda depends partly on the interest already taken by the general public in education and partly on their suggestibility, and what Americans call "the magic of 'together'."

In England a notable success was achieved last year by the West Ham Education Week. This year local weeks have been organised in Nottingham, Hastings, Warrington, and Gillingham, and probably elsewhere. Should an attempt be made to organise such observances on a national scale in England, experience gained in organising the National Health Weeks initiated in 1913 by the Agenda Club might afford useful precedents. The striking success of the Education Exhibitions organised in London in connexion with the Imperial Education Conference last July by the Board of Education and the London County Council's Education Committee indicates that a national Education Week, if properly managed, would appeal to a very large public. Many recent developments in the schools, such as the increased attention paid to the teaching of science, drawing, manual training, dancing and other physical training, dramatic performances, Montessori methods, the use of "educational" films, and so on, lend themselves readily to exhibitional purposes. On the other hand, there are reasons for believing that too little effort has been made to cultivate close relations between the schools and the communities they serve.

During the past twenty-five years the achievements of science have been greater than in any previous similar period of time in the history of the world, but less is done with the object of enlightening the public regarding them than in the Victorian era. A Science Week would do much to promote public appreciation of the worth of science, and among other beneficial results that might be looked for from such an enterprise is a much needed stimulation of interest in University Extension work in the field of science.

Carl von Linné.

Linnæus (afterwards Carl von Linné): the Story of his Life, adapted from the Swedish of Theodor Magnus Fries, Emeritus Professor of Botany in the University of Uppsala, and brought down to the Present Time in the Light of Recent Research. By Dr. Benjamin Daydon Jackson. Pp. xv + 416 + 8 plates. (London: H. F. and G. Witherby, 1923.) 25*s.* net.

THOSE who admire the work of Linnæus were indebted to Prof. Th. M. Fries in 1903 for a new life of his great predecessor at Uppsala. Members of the Linnean Society of London now have to thank their general secretary for an English epitome of the Swedish work.

Linnæus accounted himself "a born methodizer." His contemporaries thought so too, and this belief is entertained still, both by those who appreciate and by those who belittle what Linnæus accomplished. But while his work justifies his own estimate, that estimate does him less than justice. Linnæus failed to foresee that in one country dialectic aptitude would eventually so affect ability to grasp principles as to induce discrimination between "pure mathematics, astronomy or any branch of science which aims merely at describing, cataloguing or systematizing," and philosophic activities that afford scope for "experimental research." He could scarcely have predicted that, in another country, the tendency to see ahead would so affect ability to look around that Linnæus could no longer be considered a botanist.

The Linnæus of the "Lachesis Lapponica" was a great naturalist of uncommon judgment, with an inborn capacity for observation. The Linnæus of the "Musa Cliffortiana" had a decided capacity for physical experiment, which later tasks hindered him from exercising to the full. Linnæus regarded the improvement of natural knowledge for use as important as its improvement for discovery; in his travels as a student and his later journeys on public commission, economic and scientific questions received equal attention. His biological study revealed the defects of received classifications; his economic instinct suggested the need for reform; his philosophic interest in the "mystery of sex" supplied the means.

Linnæus found the basis of method to be the recognition of natural kinds; the practical segregation of these into sorts and strains, and their theoretical aggregation into septs and clans. These tasks may proceed either by synopsis, which involves arbitrary dichotomy, or by system, which entails considered arrangement. Synthetic in mind, Linnæus thought system, however crude, preferable to synopsis, however complete, and so improved a by-product of scientific investigation as to substitute order for chaos in the domain of Nature. Linnæus did not claim that the system he outlined on May 11, 1731, when he was only twenty-four, added to real knowledge; its purpose was to serve economic ends by rendering real knowledge usable. Those who decry and those who excuse the artificial nature of his sexual system, alike overlook what Linnæus taught. His artificial higher groups were meant to serve as substitutes for natural ones, only until the latter had all been detected. Like his precursors, Morison and Ray, Linnæus strove to decipher the real system of Nature. Extending their studies, he laid the foundation of that system, and only refrained from applying it in practice lest those who improve natural knowledge for use be thereby deprived of a thread to guide them through the maze of things. Others have followed Linnæus along the path opened up by Morison, and have devised systems as workable as the pragmatic method of Linnæus. Modern students of the "mystery of sex" are, however, at times inclined to think these "natural" systems almost as "artificial" as the Linnean "sexual system."

Until Bauhin in 1623 enumerated the plants he knew with reference to their names, it was usual for those who reproduced old descriptions to devise fresh designations. Linnæus gave stability to Bauhin's reform when, in 1753, he enumerated the names he knew with reference to the plants concerned. For Linnæus the naming of kinds was a responsibility so grave that he made the genus "a thing of dignity." The name of a sort was, for him, necessarily that of its kind combined with a differential statement, and the relationship of a specific to its generic name was that of the bell to its clapper or the clapper to its bell. The purpose of scientific nomenclature is so akin to that of heraldic achievement as to suggest that the use by Linnæus of "trivial" epithets, ancillary to yet distinct from specific names, may have been taken from the older and rigorously disciplined technology which employs "crests" as ancillary to, although independent of, "arms." While advantageous in applied study, these "trivial" terms have proved a mixed blessing in descriptive work. Linnæus was himself so immune against both the juvenile tendency to confuse means with ends, and the adult liability to care more for names than things, that he did not foresee the later retreat from philosophical positions secured by him for science. Histories of natural "families" now supplant accounts of "genera"; now, the "trivial" terms designed by him as aids in economic work are often mistaken for specific names and sometimes treated as entities apart. The efforts to stabilise nomenclature, which this abandonment of sound scientific principles has entailed, involve results so bewildering that one

fervent hope of the applied worker is the appearance of another Linnæus.

British naturalists who know what Linnæus did will welcome most the possibility now afforded them of realising what Linnæus was. Thanks to the piety of Prof. Fries, our belief in the courage of his youth and the high purpose of his whole career is more than confirmed. We learn with relief that the tales of injustice done to him were never countenanced by Linnæus, and gather with satisfaction that these acts of injustice never occurred. The story of an averted duel was evolved from the inner consciousness of a German admirer after both Linnæus and Rosén were dead. The circumstantial account of his strained relations with Browall is a fable as impossible as it is impertinent. The frigate despatched to recover his collections is a figment of English artistic fancy. If we regret the loss of the legend of the gorse on Putney Heath, we do so less because of the story than because we learn with sadness that Linnæus did not love our nation. We find compensation in this opportunity of seeing ourselves as others see us, and take comfort from the assurance that his feeling was not due to the insular reserve, not to say frigidity, which marked his reception in Great Britain in 1736. The many acts of kindness subsequently done to him by both, effaced from his memory the original misjudgment, by Miller of his capacity, by Dillenius of his aims. What Linnæus was unable either to forget or forgive was that the English should have permitted Sweden to purchase, for the paltry sum of 15*l*., the priceless West Indian collection of Dr. Patrick Browne. Looking back through the mist of years to 1758, we may perhaps pardon the generous indignation of Linnæus at English philistinism. We can at least appreciate his feelings, and if we do not share his anger, this is only because we know that the spirit he disliked is as rampant now as it was when Linnæus lived.

Fortunately, Linnæus was spared the knowledge that this spirit is not peculiar to our nation. Inwoven in the web of his scientific thought we find a silver thread of faith in Divine Providence. But, alongside this, there lay a thread of darker hue. For the guidance of his son, Linnæus noted instances, in his own experience, of "Nemesis Divina." Was the feeling aroused by English disrespect towards the collection of Browne the reflex of a subconscious dread lest like disrespect be shown towards his own? Fate ordained that the collection of Linnæus should come to England, and Sweden knows that it has been guarded here with all the respect and care that Sweden has shown towards the Jamaica collection the study of which caused Linnæus to neglect "friends, relations, house and fatherland." History, for once, can point to a case in which the contemplation of parallel injuries has increased mutual regard, and has helped to cement the ties that link two kindred and friendly nations.

Chemistry of the Metals.

(1) *A Treatise on Chemistry.* By the Rt. Hon. Sir H. E. Roscoe and C. Schorlemmer. Vol. 2: The Metals. New edition completely revised by B. Mouat Jones and others. Part 1. Pp. xv+829. Part 2. Pp. viii+831-1565. (London: Macmillan and Co., Ltd., 1923.) 50*s*. net.

(2) *Metals and Metallic Compounds.* By Ulick R. Evans. In 4 vols. Vol. 1: Introduction, Metallography, Electro-Chemistry. Pp. xii+468. 21*s*. net. Vol. 2: Metals of the "A" Groups. Pp. xi+396. 18*s*. net. Vol. 3: The Transition Elements. Pp. xii+270. 14*s*. net. Vol. 4: Metals of the "B" Groups. Pp. xii+350. 18*s*. net. (London: E. Arnold and Co., 1923.)

(1) THE last revision, in 1913, of volume ii. of Roscoe and Schorlemmer's "Treatise" carried the volume up to the largest convenient dimensions for binding. The present revision has resulted in the separation of the volume into two parts, each containing some 800 pages, as compared with nearly 1000 pages in the volume on the "Non-Metals." Once more the revision has been carried out in such a way as to preserve fully the original character of the work, and many readers would have been disappointed if any other policy had been adopted. On these lines much valuable new information has been included in the volume, which will continue to occupy an unique place in English chemical literature. It is, however, a matter of opinion how long this policy should be continued in view of the increasing extent to which modern inorganic chemistry is being developed on physico chemical lines. Sooner or later, it will probably be necessary to introduce equilibrium-diagrams in the text and to deal with chemical processes in which reversible actions are used on a more definite physico-chemical basis.

The revisers have been perhaps a little too careful in retaining old matter in the text. The full details which are still given of the Leblanc soda process and of the Bessemer process for steel are really of historical interest only now that the last Leblanc plant and Bessemer converter have been shut down. It is a question whether they ought to be retained as a part of the systematic teaching of chemistry merely because a generation will probably elapse before they cease to be the subject of possible questions in examinations.

The crystallographic sections of the book have been fully revised by Mr. Barker; but it is a pity that th

new illustrations are so easily distinguished from the old by the rougher way of reproduction. The spectroscopic sections have not received a similar revision, and do not therefore give a correct impression of the modern position of the subject. Thus the apparatus "best suited to ordinary chemical purposes" is still apparently that of Bunsen, and his recommendations for mapping spectra are retained. Again, modern work on spectral series will obviously occupy an important position in the next edition, but is very barely touched upon in the present issue. The descriptive chemistry is, however, as good as ever, and the new edition can be heartily commended as one of the best available books on this aspect of the science.

(2) Mr. Evans's four volumes on "Metals and Metallic Compounds" cover a few pages less than the two parts of vol. ii. of Roscoe. He has the advantage of starting *de novo* and has made free use of this liberty by developing fully the chemical points that are of special interest to a metallurgist. The book is, however, definitely a chemical rather than a metallurgical treatise, since the compounds of the metals are described as fully as the elements themselves. To one who is interested in the broader aspects of the science, it is nevertheless refreshing to find a chapter of the introduction given up to geo-chemistry. This introduction is followed by chapters on metallography and electro-chemistry, which complete the first of the four volumes.

The systematic description of the individual metals and their compounds in the remaining three volumes is very wisely based upon the long periods rather than the short periods of Mendeléef's classification. In this way the natural sequence of alkalis, alkaline earths, and earths (rare or otherwise) is preserved, while copper is grouped with the heavy metals to which it is closely allied. The "eighth group" metals occupy the third and smallest volume of the series, while the second and fourth volumes deal with the elements which occur in the earlier and later octaves of the long periods, together with their obvious homologues in the two short periods. Throughout these volumes the impression is maintained that the author is a geochemist and a metallurgist as well as a chemist, and that he has an up-to-date knowledge of modern technical operations as well as of pure chemical science. His references to technical and semi-technical literature are likely to prove of special value, since, although literature of this kind may be of relatively transitory importance, it is much less accessible to the ordinary chemical student than the literature of pure chemistry, to which existing text-books form a sufficient guide.

In view of its special characteristics, Mr. Evans's treatise does not enter into direct competition with any other work on chemistry, at least in the English language. It will probably appeal in a special way to chemical students with a leaning towards the practical side of the subject, to metallurgists and to engineers; but it will also serve as a work of reference by means of which chemists in general may trace out items of interest which are not noticed in books of a more conventional type. It can therefore be highly commended as an original work of more than average merit, on the prompt completion of which the author may be congratulated.

Alpine Tectonics and other Problems.

(1) THE current theories of Alpine structure are based on two main explanations. According to one, Alpine mountains consist of bands of the crust which have been crumpled by contraction consequent on the diminishing size of the earth. According to the second explanation—the *Versluckung* or the swallowing theory of Schwinner—a band of the crust sinks into a lower zone, and there undergoes intense compression, accompanied by the metamorphism of its rocks.

Dr. F. Heritsch, of Graz, discusses these two hypotheses in a masterly survey of the principles of Alpine geology. He deals mainly with the Eastern Alps. The treatment is very technical and would be easier to follow if illustrated by a general sketch map. The first part of the book consists of a series of essays on the principles of rock folding; he therein discusses the nature of geosynclines, of local and widespread movements of the crust, and the formation of foredeeps. In his account of the widespread or epeirogenetic movements he lays stress on the oscillation which often accompanies variations in coast levels. He then discusses the phenomena of folding, overfolding

and overthrusting; he deals mainly with observed examples, as he regrets that tendency to consider folding from general principles which has often led to a geometrical rather than a geological treatment of the problems. He next deals with the behaviour of rocks under pressure and gives an excellent account of dynamometamorphism, mylonitisation, and the plasticity of rocks.

The largest part of the book consists of an account of the structure of the Alps in which the author insists on the "impossibility" of the overthrust theory in its present dominant form. He supports the "swallowing theory" which represents the crust of the earth as being under conditions analogous to those of the atmosphere. In certain areas, which correspond to the anticyclones, the movement of the material is upward, leading to the formation of volcanoes and the rupturing of the crust. In other areas, which correspond to cyclones, the crust moves downward, producing fold mountain chains owing to the lateral pressure, and also widespread metamorphism. Overthrusting inevitably takes place in the subsiding area, but the thrusts have a more limited horizontal extension than is claimed by the upholders of the *Deckentheorie*, which in its extreme form Dr. Heritsch describes as mere phantasy. The swallowing theory is, however, not inconsistent with the general contraction of the earth. It in fact renders that process more probable by rejecting the immense horizontal overthrusts which are too great for contraction alone to explain. The deformation of the earth by contraction indeed supplies the power which is required for regional uplifts and causes the subsidence of the intensely crumpled bands which have formed the fold mountain chains at different places at successive periods in the earth's history.

Dr. Heritsch's book is an able and sane statement on a complex branch of geology. It should be a useful corrective to the exaggerations of one school of Alpine geologists.

(2) North of the Alps lies the province of Württemberg, which has been affected by some of the Alpine movements but presents a marked contrast by its comparatively simple though varied geology. The province has played an important part in the history of geology. Tübingen has been one of the great geological schools of Germany, and, as Dr. Hennig reminds us, both Kilima Njaro and Kenya were discovered by men of Württemberg, though they were both at the time in the service of a British Missionary Society. The richness of Württemberg in fossils made it one of the chief centres of German palæontology, and the museums of Tübingen and Stuttgart are so rich in types that they have attracted generations of geological pilgrims. The province includes one of the most typical series of Jurassic rocks, an illuminating group of pygmy volcanoes and structures throwing light on the physical and glacial geography of the northern Alps.

The comprehensive summary of the geology of Württemberg prepared by Prof. Hennig, of Tübingen, is therefore welcome, as it gives an up-to-date summary of the German Jurassic system and a guide to the localities made famous by the work of Quenstedt. The first part has been issued, and it deals with the orography and with the stratigraphy up to the end of the Jurassic. The two sections of this part which will be of widest interest are the account of the Trias with its rich development of the Muschelkalk and of the Suabian Jurassics, which include the rich coral reefs for which the locality of Natheim has been especially famous.

The book is illustrated by two excellent coloured maps, one of the orography and one of the geology of Württemberg, by many clear diagrams of the palæogeography and lateral variations of the rocks, and a correlation of the English and German Jurassic deposits. In the author's classification of valleys, p. 7, he uses the term "isoclinal valley" for those in which the dip is the same on both banks owing to the valley having been cut in an inclined sheet of rock. This term is so likely to be confused with an isoclinal in which the equal dip on both sides of the axis is due to overfolding, that it is to be hoped that the new usage will not be generally adopted; for such valleys either the terms uniclinal or homoclinal are available.

(3) Forel's "Handbuch der Seenkunde," the standard text-book on the physical geography of lakes, was published in 1901, so that a new work was desirable, and the previous writings of Prof. Halbfass, of Jena, have shown, by his wide knowledge of the scattered literature on the subject, that he is especially competent for its preparation. His book is based on the principle that the essential feature of a lake is its water and not its basin. Hence a larger part of the volume is devoted to the physics and chemistry of lakes than to the nature of their basins. He discusses the movements of lake waters due to thermal changes, and to seiches, and variations of the shore lines caused by the tilting of the crust. There are short chapters on the optical and acoustical properties of lakes, including in the latter the "Barisal guns," which appear, however, to be due to seismic influences on delta deposits and to have no connexion with lakes. The mirage effects in some Hungarian lakes are illustrated graphically by a series of views taken at intervals during the day. There is an especially useful summary of the chemistry of lake waters. The chapter on the biology consists of only two pages; it considers the relations of some animals living in deep lakes and accepts them as

survivals from a cold-water fauna which had a widespread distribution at the end of the glacial period.

In dealing with the variations of lake levels, Prof. Halbfass discusses the asserted dessication of the continents. This view he dismisses most emphatically. The fall in level of many lakes he attributes to artificial influences, and he holds that lakes in all parts of the world show that there has been no general lowering of their level in historic times. He refers especially to Lake Chad, which he says is placed in the first line by the "dessication fanatics." He holds that this lake gives them no support since Marquardsen has shown that for eighty years after the visit of Denham (*i.e.* from 1824 to 1905), the boundary of the lake has remained essentially the same. In dealing with this problem he refers to Bruckner's thirty-five-year climatic cycle period, which he says is not confirmed by the evidence of the lakes of at least four of the continents; yet he holds that there is an actual climatic period, which is three times as long as the Bruckner period.

In the chapters on the distribution and origin of lake basins Prof. Halbfass rejects their glacial origin, except in so far as many of them occupy hollows in drift, or are held up by moraine dams. He rejects not only the glacial origin of deep rock basins but of many lakes of the Baltic Plain for which glacial denudation seemed far more probable. He adopts the views of Wahnschaffe and Jentzsch that these basins are due to tectonic subsidences, and in some cases, such as that of the Rogasener Lake in Posen, the basin, though now all covered with drift deposits, was pre-glacial in origin. In dealing with this problem Prof. Cotton's book (4), which is a general summary of physiography illustrated by examples from New Zealand, is less in accordance with recent opinion; for he represents the New Zealand fiords as glacially cut troughs of which the lower parts have been filled by the sea. They appear to agree with those of Norway, where the overwhelming balance of opinion is in favour of the pre-glacial age of the fiords. Prof. Cotton has an exceptionally fascinating subject, as New Zealand is especially rich in clear examples of geographical processes.

The book is well illustrated and his views are clearly stated. It illustrates the growing extent to which some schools in Australasia are dominated by American opinion; this fact, in the case of geography, is easily explained by the attraction of that logical scheme of geographical evolution for which we are deeply indebted to Prof. W. M. Davies. The extent to which British work is overlooked may be judged by the bibliography. Of the 59 memoirs quoted only five are British, and they date from 1802 to 1876, the latest contribution in this list by any British worker being Thomson's paper on the windings of rivers.

Our Bookshelf.

Theorie der Kristallstruktur: ein Lehrbuch. Von Prof. Dr. Artur Schoenflies. Pp. xii + 555. (Berlin: Gebrüder Borntraeger, 1923.) 18*s*.

APART from its obvious indispensability to the specialist, this new edition of the author's former "Krystallsysteme und Krystallstruktur" (1891) would seem to bear a character of wider significance, as showing that wisdom is justified of her children. There can be few such signal instances in science in which an abstract and apparently unverifiable theory has been so rapidly brought within the ambit of the experimental method, and proved to be equal to all demands. It is, therefore, peculiarly appropriate that one of the original founders of the modern theory of crystal structure should return to his subject in the light of recent X-ray developments. By including a discussion of those points in which the theory is still ahead of experiment, the author contrives to confer on his work a new prospective value.

The book is, of course, mainly concerned with a systematic development of the 32 classes of symmetry and the 230 possible ways in which matter may be properly disposed throughout the space occupied by a crystal. The general arrangement is necessarily much the same as before, but the exposition has been vastly improved in at least one particular. The former edition was solely addressed to the mathematician, to whom the addition of anything of the nature of a diagram (unless it take the special form of a symbol) would presumably impede the working of pure thought. The present work is rather directed to the crystallographer and X-ray analyst, and is therefore illustrated with structural diagrams, praiseworthy alike in quality and quantity.

In view of the existence of such an authoritative treatise as the Braggs' "X-rays and Crystal Structure," the author has refrained from entering into any account of the practice of X-ray investigation. It is, however, evident that the actual results are fully appreciated, for considerable space is devoted throughout the text to a systematic treatment of the relations between the number of particles (as also their symmetry) and the various positions they occupy in the structure. Moreover, a special chapter is devoted to space-partitioning and the packing of equal spheres; whilst another, possibly the most important of all, deals with selected cases investigated by X-ray workers. This inevitably leads to a discussion of the possible influence subatomic structure may exert on the physical manifestations of a crystal, and to a final conclusion that the only possible way of further progress is along the path of experiment.

It may be added, in conclusion, that those qualities of clear and concise expression, which have always made Dr. Schoenflies' writings the most favoured original source in the domain of crystal structure, are fully preserved. By bringing out so valuable a work in the face of obvious contemporary difficulties, both author and publishers have placed a wide-spread body of workers under a debt of gratitude, which they can scarcely ever discharge.

T. V. B.

The New Natural History: Being the Twenty-Fifth Robert Boyle Lecture delivered before the Junior Scientific Club of the University of Oxford on 6th June, 1923. By Prof. J. Arthur Thomson. Pp. 19. (London: Oxford University Press, 1923.) 1*s.* net.

In this refreshing and stimulating address Prof. J. Arthur Thomson pleads for the retention of the term natural history as a designation for the study of the habits and surroundings of animals and their inter-relations with one another—the new natural history—and for its more honourable recognition as a well-defined and integral department of biological science.

Out of the ashes of the old all-embracing science of natural history, the author traces the growth of the new science under the influence of various factors which have moulded its development. Chief among these is the recognition and appreciation of the great fact of the inter-relations of living organisms in the web of life and the external linkages between animals or animals and plants—the central Darwinian idea of the correlation of organisms. This has given direction and stimulus to the study of natural history and forms one of the guiding principles of the new science. No less important is the new and more precise scientific outlook on the question of animal behaviour, due to the work of Lord Avebury, Romanes, and especially Lloyd Morgan, who laid the firm foundations of an experimental comparative psychology, and to Loeb, who has done so much to develop the question on the physiological side. From the somewhat chaotic mixture of anthropomorphism and automatism there has emerged a precise science that distinguishes instinctive from intelligent behaviour and both from tropisms and forced movements.

A third factor which has given precision to the observations of the field naturalist and a new significance to his facts is the idea of evolution. With this as a working hypothesis the student of natural history has been stimulated to discover how a particular structure or function is fitted to a particular situation, and the study of adaptations has developed into an important and exact science.

The vision of the new natural history as a study of "animal personalities at various levels, as creatures with mental aspects, as agents that seek after well-being and share in their own further evolution, as threads in a quivering web of life" is indeed an inspiring one. Prof. Thomson justifies his plea, and the recognition which he asks for cannot be long withheld.

Alternating Current Electrical Engineering. By W. T. Maccall. Pp. viii + 493. (London: University Tutorial Press, Ltd., 1923.) 15*s.*

A fairly complete résumé of practical alternating current theory is given in this work. In order to keep the subject matter within the limits of one volume the explanations have to be made very concise. It is therefore more suitable as a class book than for reading by the private student. It covers a very wide field. The theory is now beginning to crystallise, and so numerical examples have been introduced which will enable the student to test the thoroughness of his knowledge.

The book is on the whole well written. The author sometimes gives results as if they obviously followed from the given premisses; for example, in describing how two induction motors are connected in cascade, he says that the supply mains are connected to the stator of one motor and its rotor is used to supply power to the second stator. "The result is that the synchronous speed of the combination is that of a motor whose number of poles is equal to the sum of the number of poles of the two motors." This is a hard saying, and we hope few readers will accept it without trying to make up some proof for themselves. If the author made the distinction between "average power" and "instantaneous power" clearer the proofs of the two and three wattmeter methods would be greatly improved. At the foot of page 61 a reference is made to the instantaneous value of the average power. A vector proof is given of the three-voltmeter method of measuring power, and it is stated that it should not be used unless the wave forms are nearly sine shaped. The ordinary algebraical proof shows at once that it is true, however distorted the wave forms may be. The Behrend definition of the leakage factor of an induction motor is given, and one of the methods described of determining its value is by Behn-Eschenburg's formula, which applies to a totally different definition of leakage factor.

Popular Fallacies Explained and Corrected (with Copious References to Authorities). By A. S. E. Ackermann. Third edition. Pp. xvi + 984. (London: The Old Westminster Press, 1923.) 12*s.* 6*d.* net.

To every one who has made a special study of any particular branch of human knowledge there must, at some time or another, have come a feeling of surprise at the large number of errors which exist in the popular mind regarding his own, and therefore presumably every other, subject. The previous editions of this book have proved of immense value in helping to correct the many errors which still persist in spite of the progress of popular education and the many devices now used for the dissemination of accurate information. A very real welcome is, therefore, assured for this, the third edition, which has been so extended in scope that it has become almost a new work. The number of fallacies dealt with has been increased from 460 to 1350, and these cover practically every branch of human activity. Indeed, so wide is the field covered, that a reviewer may be pardoned for paying particular attention to those sections by which he may expect to be best able to judge of the value of the whole. Engineering, general science, and astronomy receive their full share of attention at the author's hands—as might, indeed, be expected from one whose qualifications lie particularly in the first-named subject—and a close perusal of these sections has abundantly demonstrated the painstaking accuracy of the author's work. As Sir Richard Gregory points out in an appreciative introduction, a valuable feature of the book is the constructive work which it does in giving the truth of any matter concerning which an error is exposed. In conclusion it should be mentioned that the book is written in an eminently readable style, not unenlivened with touches of genuine humour. It is, moreover, well printed and may be cordially recommended as a useful addition to the library of general knowledge.

Heat and Energy. By D. R. Pye. (Clarendon Science Series.) Pp. xii+211. (Oxford: Clarendon Press; London: Oxford University Press, 1923.) 5s. net.

As stated in the preface, this book is not designed to be a text-book in the ordinary sense of the word. It is intended to be read by the advanced schoolboy to supplement the detailed instruction he has received in the class-room and the laboratory, with the view of imparting a broader conception of energy in its different forms. The first six chapters are devoted to heat, the chief phenomena being described and explained with less detail than is customary in the ordinary text-book. The relation between heat and work is then dealt with, followed by chapters on energy as light and sound. The remaining part of the book is taken up with practical applications of energy in the production of power, warming, ventilation, and refrigeration, the principles involved being clearly explained.

On these lines the author has produced a very readable volume, but it is difficult to see why he fails to give an account of electricity as a form of energy, as in these days almost every boy is interested in electricity through the medium of "wireless." A further addition, in the form of a few pages on the measurement of high temperatures, might be recommended, not only because of the practical importance of the subject, but also for the interest it creates in the mind of the young student of science. Apart from these omissions, however, there is no doubt that the careful reading of this book by an intelligent schoolboy would give him a much wider outlook than that provided by the ordinary text-book. C. R. D.

The Dance of Life. By Havelock Ellis. Pp. xiv+340. (London, Bombay and Sydney: Constable and Co., Ltd., 1923.) 12s. net.

THE main contention in "The Dance of Life" is that life is an art, as its expressions in morals and religion (which the author calls "mysticism"), in writing and thinking, and even in science, are arts, appropriately typified by the art of dancing. Life, in all its forms, is creative, the result of an impulsive outflowing. Accordingly, rigid laws, externally imposed, are really inapplicable to it. The dynamic is refractory to regulation by the static. What law there is must needs be from within; the formulation of the impulse of which it is the law. Mr. Havelock Ellis is not the only prophet of this doctrine in recent times; and, indeed, its underlying thought is a very old one indeed—a thought never quite forgotten even when the dynamic movements of reality were caught and crystallised in the static formulæ of philosophy and science. But it is none the less, when stated in isolation, a paradoxical view; and not least so when it is applied to a solution of the social problems of the present day. Yet "The Dance of Life" is a very stimulating and, indeed, challenging book, in itself a work of no mean art. Though in appearance roughly flung together, its several chapters have a single thread of thought—the view to which allusion has been made—running through them all. Philosophers of many schools and men of science alike may find much to disagree with in this book; but none can read it without interest, and few without some profit.

The Subject Index to Periodicals, 1920. Issued by the Library Association. F: *Education and Child Welfare.* Pp. 29. (London: Grafton and Co., 1923.) 4s. net.

THE Library Association maintains in this section of its Subject Index the high standard of quality of the earlier issues, but when one compares it with the American "Readers' Guide," the 1919–21 volume of which was published last year, one cannot but regret that the English Index is so deeply in arrear. It is true that it gleans over a much wider field, but it is questionable whether it would not be better to speed up the work even though this should necessitate some restriction of the sphere of operations. In this Education and Child Welfare section, professional and technical education, mental tests, the teaching of citizenship, languages (especially Latin), economics, geography, mathematics, and religious education all figure largely.

The articles indexed under science teaching are chiefly from the *School Science Review* and *Parents' Review*, but include some from the *Revue Pédagogique*, *Science Monthly*, and NATURE. The quarterly *Educational Record* published by the American Council on Education does not appear to be included within the scope of the work. It contained in 1920 important articles by President A. T. Hadley, Prof. G. D. Strayer, Dr. S. P. Capen, and other well-known authorities, which might with advantage have been mentioned in the Index.

Outlines of the Calculus for Science and Engineering Students. By Dr. Terry Thomas. Pp. 127. (London: Mills and Boon, Ltd., 1922.) 3s. 6d. net.

MANY students will find Dr. Terry Thomas's latest book of considerable value, not for private study of the subject, but also for use with oral lessons and for revision purposes. Although Dr. Thomas's brevity is a welcome change from the prolixity of some recent mathematical text-books, it is yet too pronounced a feature in the present volume, reducing the subject-matter almost to the tabloid form. The course is nevertheless a very suitable one and the examples are well chosen.

One or two criticisms of detail may perhaps be useful to the author if a second edition is called for. The "don't" of p. 10 is transgressed by the author himself on pp. 34, 75, etc. Students should be taught to distinguish between ordinary and partial differentiation as regards symbolism: it saves a good deal of trouble. The example chosen on p. 80 to show the "impossibility" of separating x and y is rather unfortunate. S. B.

Supplementary Notes on Gravimetric Analysis for Beginners. By W. Lowson. Pp. vi+58. (London: Longmans, Green and Co., 1923.) 2s. 6d.

THESE notes are intended to be used in conjunction with regular text-books. There are many valuable hints on practical details, and items of theory which are not easily found by students. The book will be found useful by those beginning quantitative analysis (the calibration of volumetric apparatus is included), and its moderate price will commend itself to students.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Polarisation of Double Bonds.

IN the September number of the *Philosophical Magazine* Sir Joseph Thomson has applied the theory of electrostatic induction to explain the mechanism of polarisation of double bonds and of the orientation of substituents in the benzene series.

Electrostatic induction is what we have imagined to be responsible for the "general" electrical effect of a substituent by producing a kind of drift of electrons in the molecule as shown in the scheme

$$Cl - + C_1 - + C_2 - + C_3 - + C_4 - + H$$

and we have attributed the superposed alternating polar effect to other causes, and predominantly to the laws of valency in their application to polarised complexes. In such a system as that depicted above, Sir Joseph Thomson suggests (p. 511) that as the result of the existence of the electrostatic doublet between Cl and C_1, electrons will crowd into C_1 from C_2, and into C_3 from C_4, and thus an alternating condition will be brought about in the chain. But for the same reason that electrons pass from C_2 into C_1, it would seem to us that electrons should also pass from C_3 into C_2, and the effect would then be continuous although diminishing in degree along the chain. The precise manner in which the difficulty is overcome is not quite clear, but we gather that Sir Joseph Thomson holds that electrons may pass from one carbon atom to another, if these are joined by a double bond, but not if they are joined by a single bond, which view would require the acceptance of the Kekulé benzene formula in its simplest form, and would be contrary to all the indications of modern researches on the conjugation of ethylenic groups and on intra-annular tautomerism.

A much more obvious, though not more serious, objection to Sir Joseph Thomson's method of deduction of the alternate effect is that while it leads to the right result in fifty per cent. of the cases, it leads to the wrong result in the remaining fifty per cent. For example, the direction of polarisation of the double bond in vinyl chloride, the example which Sir Joseph Thomson himself selects, is just the opposite of what experiment indicates. Thus, he provides the carbon atom which is attached to the chlorine with a greater density of electrons than the other, as indicated by the symbol $CH_2 \cdots CH \cdot Cl$, where the lower dotted line represents, say x electrons, and the other represents $2 - x$ electrons, the whole symbol thus indicating an augmented electronic density on that side of the double bond which is nearest the chlorine atom and a decreased density on the other carbon atom.

Now, it is easy to see that this process tends to produce a positive charge on the CH_2 carbon and a negative charge elsewhere, and consequently the carbon atom of the CH_2 group should, if anything, attract negative ions, and the product of the action of hydrogen chloride on vinyl chloride ought to be ethylene dichloride $CH_2Cl - CH_2Cl$. But, as Sir Joseph Thomson correctly states on p. 508, it is the carbon atom to which halogen is attached in a substituted ethylene which attracts negative ions. Were it proposed to escape this dilemma by assuming that the atom with the diminished density of electrons is the one which is ultimately found attached to the positive ion or radicle of the reactant, then further difficulties emerge and, for example, in the group $C_3 = C_2 - \overleftarrow{C_1} = O$, it would be necessary to postulate a passage of electrons in the direction indicated by the arrow in order to reconcile Sir Joseph Thomson's theory of the mechanism of induction with the experimental fact that invariably C_3 is the atom which is found attached to the negative radicle or ion of the reactant. Without going into detail it is obvious that similar considerations apply to orientation in the benzene series.

Finally, the classification of atoms as "chemically active" or "chemically inert," according as there is a defect or excess of electrons respectively, is unsatisfactory, since both types appear to be reactive under the correct conditions. Charged centres in polarised molecules are analogous to charged ions and it is difficult to see why the comparison should not be extended to their reactions.

River Pollution.

THE Salmon and Freshwater Fisheries Act, 1923, will come into operation on January 1 next, replacing the many Acts, beginning with that of 1861, which have been framed to regulate the fisheries of our inland waters. The first of the series contained a clause relating to the pollution of rivers, and this clause has up to now been practically the only statutory control we have had. It was reinforced by the River Pollution Prevention Acts, and this legislation was sufficient to prevent sewage being poured in an untreated state into rivers, but not into estuaries, and it proved ineffective in preventing poisonous effluents from industrial concerns contaminating both.

The new Act defines rather better the nature of the pollution which will be regarded as an offence (Section 8), empowers fishery boards to institute proceedings under the River Pollution Prevention Acts, 1876 to 1893 (Section 55), and provides (Section 73) for cases being tried before the nearest court of summary jurisdiction.

The rivers in the meantime have been allowed to get into a serious state of deterioration, due to the great developments of population and of industries. Our legislation hitherto has prevented any undue contamination by sewage of the non-estuarine parts of the rivers. It was really strong enough to prevent pollution by effluents from commercial works. But the dominance and importance of the industries have been usually overpowering, with the result that many of our rivers and streams have been allowed to get so severely polluted that they are almost, or altogether, devoid of life. The estuaries, with the growth of industries and of towns and cities, have been exposed to pollution from trade effluents to a greater extent than the river, and have had to carry a steadily growing burden of sewage. The result, as is well known, is that some estuaries are so badly polluted as to prevent the passage of migratory fish, and many others have got near the same state. With the advent of the new Act we have inherited an interesting and important problem, a problem which, like previous legislation, is a product of the industrial growth of the Victorian period.

Already some progress has been made by experiment and inquiry to state more distinctly the problem and the solution. The Ministry of Agriculture and Fisheries has shown its sympathy and its appreciation of the condition of the freshwater fisheries by appointing a Standing Committee on Rivers Pollution, and

by instituting Sub-Committees for some of the important watersheds. But it is difficult to understand the attitude of the Ministry of Health and of medical officers. At two recent inquiries relating to new sewers which were designed to discharge sewage untreated into an estuary, the representative of the Ministry of Health admitted that the estuary was already overcharged with sewage, but said that the new sewers would not alter that aspect of the question, that the estuary was so bad now that it would by this addition be very little the worse.

The medical officer goes further. He says the deaths of the fish in the estuary are caused entirely by trade effluents, and that we should get more powers to deal with such pollution. As for the sewage, he will tell you that no matter how great the quantity it is not unhealthy, it is not in any way related to the destruction of fish, and he will produce statistics to show that the healthiest parts of the county and the city are just where the sewage contamination is heaviest.

Without attempting at present to deny the truth of his extraordinary statements or presuming to explain the reason for his making them, it ought to be pointed out that, even if he is right, he is arguing that it is not necessary in any case to treat sewage, and therefore that authorities everywhere should be freed from the necessity and the expense of doing so. Indeed, we should not lose sight of the fact that if the killing of the fish in the river from whatever cause proceeds to the phase of practical extermination, an important and essential feature of the river will come to an end, nor of the probability that the authorities throughout the watershed will object to being subjected to an expense no longer necessary. The river in such a case would be converted into a sewer, a condition which is already met with in some of our estuaries and rivers. The river boards, on the other hand, are desirous to preserve the rivers as rivers, and to save them from becoming sewers.

The experiments which have been made with reference to the estuary of the Tyne have demonstrated plainly (1) that it is over-polluted with sewage; (2) that it is frequently little better in composition than the liquid outflowing from the sewers; (3) that the sewage in the region opposite Newcastle is the cause of a serious diminution in the quantity of dissolved oxygen; (4) that the oxygen frequently descends below the limit necessary to sustain fish life, and is only restored by freshets from the river; (5) that in consequence, during dry weather conditions, many deaths occur, either by direct poisoning or by the lack of oxygen. It has been proved by experiment, moreover, that the sewage alone will cause death, and that it may be directly poisonous to fish.

It is obvious, therefore, that in the case of the Tyne and of many other rivers of our country, both the river and the estuary will have to be cleaned. In the case of the river, trade effluents will have to be treated to prevent any poisonous effects. The estuary is far more important, for at present it is liable to provide an impassable barrier to fish. The solution of the problem is not an easy one, but it will have to be faced some time, and, we hope, before the barrier becomes so great that migratory fish will have ceased to enter the river.

Even with the powers conferred by the new Act, little will be accomplished unless with the sympathetic co-operation of the authorities and the owners of works. Already they have shown a strong disposition to help in the inquiries and in taking steps to minimise the effects of the effluents. As soon as it is clearly realised by all concerned that action is necessary, it will not be so difficult to indicate in what direction it should proceed.

A. Meek.

The "J" Phenomena and X-ray Scattering.

In a number of recent papers, Prof. A. H. Compton brings forward what purports to be a Quantum Theory of the scattering of X-rays. I venture to think that this theory—or more correctly system of rules—has little connexion with the phenomena of X-ray scattering as I observed it nearly twenty years ago, and as I still know it. I do not wish to write of the inconsistency or illogicality of the theoretical assumptions, for they are probably as well known to Prof. Compton as to the most careful reader. Prof. Compton seems to hope that, in spite of this, the truth will emerge. But I am compelled to state a few significant facts which are not common knowledge.

Regarding the experimental observations establishing a difference between the primary and the secondary radiations *observed* (assumed by him to be scattered radiations), I should like to point out that they date from the earliest experiments on the subject (see Sagnac; Barkla, *Phil. Mag.*, 1904; Beatty; before those to which he refers). It is very easy to detect differences in the penetrating powers between the primary and secondary (scattered) X-radiations as ordinarily measured.

The greatest difficulty has been experienced by experimenters, not in establishing a difference between the primary and secondary radiations, but in showing that they are at all similar. They have not always realised the conditions essential for this. The necessity of using soft X-radiations in order to obtain evidence of the purest scattering and the almost perfect agreement with the classical Thomson theory, I have emphasised again and again. There have been various reasons for this, some obvious, others long since observed but only recently studied. The superposed radiation excited in the scattering substance by the swift electrons constituting the secondary corpuscular radiation and the possible emission of further unknown fluorescent X-radiations are among the obvious. For many years now I have known of a further and more important source of error; this is connected with what I have called the "J" radiations, discontinuities, or transformations. The important fact, whatever its explanation, is that a beam of X-rays in transmission through matter under certain critical conditions becomes considerably more absorbable both in that and other substances. We have made scores of experiments of various kinds on this abrupt transformation; more will be said of it elsewhere. What concerns us at present is that this is of such a magnitude as would be accounted for by an absorption and re-emission of the radiation with an increased wave-length of the magnitude required by Compton—about 0·02 Å.U. But this is in the direction of propagation of the primary beam; and experiments do not seem to support this view as to the nature of the change. Absorption in this region evidently depends upon factors other than wave-length and atomic number. This is the J discontinuity which I mentioned in 1916 (Bakerian lecture) and again with Miss White in 1917 (*Phil. Mag.*, Oct. 1917).

We can now certainly say that these J transformations not only *might* produce, but actually *do* produce the softening which *we* have observed in the scattered radiation in many experiments at any rate. It is not unreasonable to suppose that it is the explanation of the changes observed by others, not only in the region of wave-lengths over which we can make a definite test, but also over the range of shorter wave-lengths, over which we are not at present able to get control.

It is impossible in the space now at my disposal to give full evidence for this; but the only rational conclusion is, that this transformation observed is not in the process of scattering but in the subsequent

transmission of the scattered radiation through the radiating substance and through the absorbers.

Prof. Compton apparently did not read between the lines of a communication to the *Philosophical Magazine* (Barkla and Mrs. Sale, April 1923); but as the results do not suit his formula he makes a suggestion of how such results might have been obtained by very incompetent experimenters. May I now suggest to Prof. Compton that, in addition to taking other very obvious precautions, he might also use soft radiations, very thin radiators, and very thin absorbers. I do not think he will then have much difficulty in obtaining scattered radiation very like the primary and very different from what would be given by his formula.

Regarding the transformations of radiations of shorter wave-length, I will only say that it is much more difficult to obtain anything like equality of penetrating power between primary and scattered as usually detected; but an explanation of this can be given,—not the ultimate explanation, but again in terms of the J transformations.

Further, let us examine the theory of the recoiling electrons. Giving the Compton formula the best chance of success, consider what would happen to the electrons in hydrogen which require little energy for their extraction. These electrons scatter as much as a similar number in other substances (Barkla and Crowther). A simple calculation shows that when the K radiation of tin is employed, the recoil electron should produce an ionisation of the order of 1/100th part of that produced in air by the same X-radiations through the ordinary long-range electrons. Now Shearer in this laboratory observed in hydrogen an ionisation as low as 0·0016 of the ionisation in air; and remarked on the strong probability of this being an over-estimate. This would be of the right order of magnitude for the effect of long-range electrons alone. Where then is the effect of ionisation by Compton's scattering electrons? It apparently does not exist.

The evidence Compton used and obtained from the study of γ-rays is necessarily much less trustworthy; the experimenters have probably never—indeed cannot have—realised the many possibilities of error. Any transformation to a softer type—or at any rate something equivalent to that—would entirely vitiate the results obtained both in absorption and scattering experiments. Without wishing to detract from the merit of the work, one may justifiably point out the difficulties of exact measurement in this region. One is led to ask: Are experiments on the diminution of scattering really trustworthy? Accurate they cannot be; they may be entirely misleading. Thus in cases we have investigated, Compton's formula holds neither for the apparent change of wave-length, nor for the energy of the recoil electrons. But we can quite easily get many of the effects of the kind Compton considers.

It is possible that the J transformation which we have observed will be explained by a theory bearing some resemblance to that of Compton for so-called scattering. This would be supported by the evidence of C. T. R. Wilson's "fish-tracks." It seems unfortunate that Prof. Compton should have applied the term scattering to a hypothetical process which is so essentially different from the scattering of X-rays as ordinarily known. The important conclusion is this—the results of experiments on scattering and the Thomson theory explaining these are absolutely untouched.

Many of the experiments upon which these conclusions have been based were obtained in collaboration with Mr. Khastgir and Mr. Stevens, in addition to those already mentioned. C. G. BARKLA.

University of Edinburgh.
November 10, 1923.

Scientific Names of Greek Derivation.

I AM glad that Sir Clifford Allbutt, in NATURE for October 20, p. 590, supports the spelling "deinosaur," although Owen wrote Dinosauria. Only a week ago I heard a university student pronounce the word as "dinnosaur." Wherever pronunciation can be helped by correcting current forms the correction is obviously of service. From this point of view we may pardon, even if we regret, Miocene and Pliocene. No one, however, has attempted to write "Plistocene." We have for some centuries converted the Latin forms *ae* and *oe* (for the Greek *αι* and *οι*) into the forms *æ* and *œ* in manuscript and in print; but this has no classical authority and can be abandoned with much advantage, as has been done in modern Latin texts. The Greek diphthong or semi-diphthong *ει* could not well be shortened into one letter in our script, and this fact provides an inconsistency for those who join *a* and *o* to *e* in transliterations from Greek or Latin. Where the word has become anglicised in form, as cœnosarc, or where, like cœnenchyma, it is not a generic or specific name, the diphthong no doubt will remain compounded; but we may, I think with wisdom, write Coeloptychium and Taenia. Moeritherium is a case that needs attention. The British Museum, which has an honourable vested interest in the mortal remains of this fascinating creature, writes the *o* and the *e* separately. The Americans, and now the Japanese, adopt the compounded form.

Dr. L. C. Purser, to whom I confide all my classical troubles, tells me that Herodotus (Book II., 148) gives the lake in the Fayūm as ἡ λίμνη ἡ Μοίριος, named from a king who would appear in Latin as Moeris. C. Stephanus ("Dictionarium historicum," A.D. 1633) prints "Mœridis stagnum"; but here again the separation of the *o* and *e* would seem advisable. I confess that I always write Cainozoic in preference to Caenozoic or Cænozoic, though the *æ* conforms best with our general usage. This term, however, never had a Latin form, and may now be regarded as an English word.

As I remarked in my note in NATURE for July 7 (p. 10), it is now difficult to be logical. The Encyclopædia Britannica gives us an article on Deinotherium, but makes us look under *di* for deinosaurs. Following Sir Clifford Allbutt, let us help pronouncers —and printers—where we can.

GRENVILLE A. J. COLE.

Carrickmines, Co. Dublin, October 28.

Is the Pentose of the Nucleotides formed under the Action of Insulin?

IN a letter to NATURE for June 16, p. 810, Messrs. Winter and Smith directed attention to their observation that the blood and certain other tissues of the rabbit contain, after injection of insulin, a substance which reacts as a carbohydrate towards the α-naphthol test, but has no reducing action on copper salts even after acid hydrolysis. Commenting on this they say: "It seems possible that the carbohydrate content of the animal body may be not appreciably diminished after large doses of insulin. The above facts would suggest that the sugar stored in the body as glycogen is converted into this peculiar form."

If I understand the suggestion correctly, it is that this unidentified carbohydrate substance is formed from glucose under the influence of insulin. If this is so, it should be present in normal blood and other tissues, but absent from those of diabetics.

Jackson has recently shown (*J. Biol. Chem.*, 1923, lvii. 121) that adenine nucleotide occurs in normal human blood. I have myself recorded its occurrence, together with other nucleotides, in the pancreas of

the dogfish (*J. Biol. Chem.*, 1921, xlv. 263), and pentose compounds, which have in many cases been identified as nucleotides, and are probably always present as such, have been found distributed through a wide range of animal tissues.

Is it possible that the carbohydrate substance referred to by Messrs. Winter and Smith is of a nucleotide nature? The nucleotides give the α-naphthol test, but there is a possibility of the pentose constituent, to which the reaction is due, escaping notice on testing a solution after acid hydrolysis for reducing power, especially if only a small quantity of material is available, moderately strong acid is used, and the hydrolysis is carried out in an open vessel at the boiling-point, since, in these circumstances, the pentose readily goes over to furfurol and is lost by volatilisation.

I hazard the suggestion for this reason. I have recently found that the tissue of the islet gland in a typical teleost fish (*Ophiodon elongatus*, Girard) is the richest in pentose compounds (nucleotides) of all the tissues of the body, notably richer than the zymogenous pancreatic tissue. Since it has been shown that the islet gland in such fishes is homologous with the isles of Langerhans in the mammalian pancreas, I have suggested, in a paper on the subject which is shortly to appear in the *Journal of Biological Chemistry*, that it would be justifiable to infer from this that the general high pentose content of the pancreas in mammals is due mainly to the presence of the isles of Langerhans.

With the view of tracing a connexion between the high pentose content of the islet tissue and its function of insulin production, I have made use of the hypothesis, put forward by Heilbron and Hollins (Rep. Brit. Ass., 1922, 396) to explain the formation of compounds of the C_5 series from those of the C_6 series in plants, that hydroxymethyl-furfuraldehyde is first formed by loss of water, and this goes over to a member of the C_5 series by respiratory oxidation. This transformation would seem to necessitate the pre-formation of an activated form of glucose, and I have suggested that the plant hormone, glucokinin, described by Collip (*J. Biol. Chem.*, 1923, lvi. 513) probably performs the function of activation.

If this is so, and pentose is formed in the animal organism from activated glucose by a similar series of steps as is postulated for plants, it seems to indicate a connexion between the production of insulin and the high concentration of pentose compounds in the islet tissue.

If there is anything in this idea it may also be applied to explain the production of pentose compounds in the blood and other tissues under the action of insulin, and it would be interesting in this connexion to determine whether adenine nucleotide occurs in the blood of diabetics.

An Uncommon Type of Cloud.

THERE are many striking cloud phenomena which may be regarded as local. While the same general laws of cloud formation prevail in all climates, yet some forms, while not radically different, display varying degrees of magnitude or intensity in certain parts of the world.

The form known as "mammato-cumulus" or "festoon-cloud" or, as called in the Orkneys, "pocky cloud," is of this nature, and while it occurs in a very pronounced fashion in Australia, the United States, and other countries, it is almost a very rare phenomenon in the British Isles, and then, as a rule, in a very "mild" form.

An illustration which is usually given to represent this type is that which appears in the "International Cloud Atlas." It is from a negative by H. C. Russell, who secured it in Sydney, Australia, in the year 1893. It shows the type in its most intense form.

Less pronounced is the illustration given by M. J. Loisel in his "Atlas photographique des nuages," from a negative he took at Chiavari in Italy in 1908.

Still less pronounced is that given in the "Meteorological Glossary," issued by the Meteorological Office, from a negative by Capt. Cave taken in England in 1915.

It may be remarked that, while almost all books on meteorology refer somewhat in detail to this type of cloud, it is very rare that any illustration from a photograph accompanies the text. The reason for this is evidently due to the fact that this type does not occur very often in the British Isles, and when it does the phenomenon is a fleeting one, lasting for only a few minutes. Having observed and photographed clouds for many years, I have only seen this type on about six different occasions and photographed it on three; even then the type was not of a very pronounced nature.

FIG. 1.

In his book entitled "Cloud Studies," the late Mr. Arthur Clayden writes: "In some countries it seems to be frequently observed, but in England it is so uncommon that the writer has only noticed it about a dozen times in twenty years, and on no one of these did it last long enough to allow of its portrait being taken."

The main feature of this type of cloud is that it occurs on the underneath surface of a large cumulus cloud, and its appearance, in its most pronounced state, is of a globular formation exhibiting a large number of well-defined rounded masses of cloud hanging downwards below the main cloud. The cloud is generally associated with very disturbed atmospheric conditions, heavy rain, and with thunderstorms.

On October 22 last, at 12.45 P.M. G.M.T., an example of this form of cloud, very pronounced for this country, made its appearance at Sidmouth, South Devon, and lasted for only five minutes. I managed to secure two satisfactory photographs of it, one of which is here reproduced (Fig. 1). It shows clearly

the spherical formations hanging downwards with clear cut edges. If the photograph be turned upside down the appearance is that of the tops of cumulus clouds as seen from an aeroplane above them.

Just as the billowy tops of cumulus clouds are due to the *ascent* of warm moist air into cooler air above, so the globular formation of the festoon-cloud must be caused by the *descent* of warm moist air into an underlying cooler stratum. This inversion of temperature is generally indicative of bad weather, and this was corroborated by the weather experienced at and after the time the photograph was taken.

The Tides.

THE great importance of the subject is my excuse for troubling you once more, very briefly, regarding it. In NATURE of July 21, I stated that, according to the present tidal theory, the tidal forces, and consequently the tides, would be just the same for a sea-depth of about 4000 miles as for the actual sea-depth of about 2 miles; and, in the same issue, your reviewer, "The Writer of the Note," agrees that this is true, or, in his own words, "that the differential motion of the oceans is determined by the vectorial excess of the forces at the earth's surface over those at its centre"; which appears to ignore entirely the depth of the ocean as a factor determining the height of the tides.

The theoretical cause of the tides is the difference of the attractions of thesun and moon at the earth's surface and centre. This difference in the case of the moon is more than twice as great as in the case of the sun; therefore, the lunar tide is more than twice as great as the solar tide. Similarly, if the earth were expanded into a hollow, spherical crust of ten times its present diameter, with its water-covered surface nearest to the moon at the same distance as now, and the moon's period of revolution also remaining the same, then the lunar tide-raising force, and consequently the tide, would be about twelve times as great as now. This is the teaching of the present tidal theory; but is it the teaching of practical mechanics and common sense? Why should the mere expansion of the earth cause a ten, or twenty, or a hundred times greater tide upon its surface, the distance of that surface from the moon, as well as the masses of the earth and moon, remaining the same as before the expansion?

Surely this is a question well worthy of discussion; and surely some of your readers are sufficiently interested and open-minded to express some opinion or argument regarding it.

EVAN MCLENNAN.

Corvallis, Oregon, U.S.A., September 3.

MR. MCLENNAN'S words "and consequently the tides" are not in accordance with dynamics and are not implied in the passage he quotes from my previous note. If the earth were all water the direct tide-generating forces within two miles of its surface would be the same as in an ocean of depth only two miles. These tidal forces are usually represented by reference to the "equilibrium tide," that is, by stating what the outer surface of the oceans would be if the water had lost its inertia without losing its gravitational properties. This outer surface would be the same in the two cases mentioned. The necessary continual adjustment of water, however, would be quite different in the two cases; in the first case the water within two miles of the surface would be largely raised and lowered by that beneath, while in the second case the water would move mainly in a horizontal direction. But owing to the actual inertia of the water the outer surface of the ocean would be entirely different in the two cases, so that the accepted theory does not ignore the depth of the ocean as a factor determining the height of the tides.

The expansion of the solid earth, with an increase in water sufficient to conserve the depth of the oceans would magnify the tides because the excess of the forces at the earth's surface over those at its centre would expand with the earth's radius. Mr. McLennan apparently finds this result of the gravitational theory repugnant to his common sense.

THE WRITER OF THE PREVIOUS NOTES.

Stirling's Theorem.

IN connexion with the recent letters published in NATURE on Stirling's Theorem, I beg to say that in a paper accepted for publication by the Academy of Zagreb on July 13, and now in print, I proved in quite an elementary manner the formula

$$n! = \sqrt{2\pi}\,.\,(n+a)^{n+\frac{1}{2}}\,.\,e^{-(n+a)},$$
$$a = 0\cdot2113249 \text{ or } 0\cdot7886751,$$

which coincides with the results published by Mr. James Henderson in NATURE of July 21, p. 97, formula (3). The error was found to be of the order of $1/72\sqrt{3}n^2$ of the calculated value, where $1/72\sqrt{3}$ is equal to $0\cdot00801875$ in Mr. Henderson's results. The formula may also be written

$$n! = p\left(\frac{n+a}{e}\right)^{n+\frac{1}{2}}$$

and the log p determined once for all. (For $a = 0\cdot2113249$, we have log $p = 0\cdot5244599$.) The work of calculation is then by no means greater than in using Stirling's or Mr. H. E. Soper's formula though the approximation is far closer. I think the doubt inferred by Mr. G. J. Lidstone in NATURE of August 25, p. 283, on the usefulness of the formulæ under discussion is not valid so far as the present one is concerned. For sufficiently large values of n, depending on the number of decimals of the tables, the result calculated from the above formula is not worse than that furnished by any other more complicated formula.

STANKO HONDL.

Zagreb, Croatia, SHS-State,
October 7.

PROF. HONDL'S simplified form of my best first approximation to the value of $n!$ follows at once from the fact that $(b-c) = \frac{1}{2}$ in my letter in NATURE of July 21. [b is Prof. Hondl's a.] The constant p in $n! = p\left(\frac{n+a}{e}\right)^{n+\frac{1}{2}}$ is $\sqrt{2\pi e^{(\frac{1}{2}-a)}}$.

We have now three approximations involving this type of expression where the index of the power is $(n+\frac{1}{2})$:

(1) $$\sqrt{2\pi}\left(\frac{n+\frac{1}{2}}{e}\right)^{n+\frac{1}{2}} \text{[Soper]},$$

(2) $$p\left(\frac{n+a}{e}\right)^{n+\frac{1}{2}},$$

(3) $$\sqrt{2\pi}\left\{\frac{\sqrt{n^2+n+\frac{1}{6}}}{e}\right\}^{n+\frac{1}{2}} \text{[Forsyth]}.$$

It is interesting to note the increase in accuracy as we proceed from (1) to (3). The errors are $1/24n$, $1/125n^2$, and $1/240n^3$ respectively. Of approximations of this type Forsyth's is by far the most accurate, but for logarithmic calculation it is rather more laborious.

JAMES HENDERSON.

Biometric Laboratory,
University College, London.

Thunderstorms and Globular Lightning.

By Dr. G. C. Simpson, F.R.S.

THERE is no real boundary between pure science and applied science, and it is inconceivable that any one whose life's work is the practical application of electricity should not be interested in all things electrical. One might, therefore, expect an electrical engineer to show at least a dilettante interest in atmospheric electricity, but one is surprised—although equally gratified—to find that the president of the Institution of Electrical Engineers devoted a large part of his inaugural address on October 18 to the discussion of the electrical potential gradient in the atmosphere and the mechanism of thunderstorms. There has been a great deal of work done on these subjects in recent years, but it cannot be said that the results have yet reached far beyond the small band of workers who are actually engaged in making the investigations. Dr. Alexander Russell has, therefore, done a good service to his fellow engineers in summarising for their benefit our present knowledge and indicating problems still unsolved.

Dr. Russell accepts the breaking drop theory for the origin of electricity in thunderstorms, but he appears unable to give up entirely the old idea that free electrons form nuclei for condensation in the atmosphere. There are certain ideas which once they have appeared in scientific literature cannot be eradicated no matter how conclusively they are shown to be wrong. C. T. R. Wilson in his classical work on the condensation of water on to ions showed two things: first, with great supersaturation water will condense, in the absence of other nuclei, on positive and negative ions; and secondly, that no condensation takes place on even the negative ions until fourfold supersaturation has been reached. This latter point is nearly always forgotten, and until some one has shown that fourfold supersaturation does exist in the atmosphere, meteorologists cannot recognise that ions play any rôle in the processes of atmospheric precipitation.

The breaking drop theory of thunderstorms has met with very wide acceptance; for it gives such a simple and complete account of the origin of the electricity and explains so many of the observed facts, such as the part played by ascending air currents, why the lightning flashes are mainly between the base and the top of the cloud, and why the rain carries sometimes a positive and sometimes a negative charge with the former preponderating.

The physical basis of the theory has been examined in great detail by Lenard in Germany and McClelland and Nolan in Dublin, and there can now be no doubt that the breaking of drops does produce a separation of electricity. There was, therefore, every justification for Dr. Russell to give the breaking of drops as the chief source of electricity in thunderstorms, but this is only a part of the complete theory of thunderstorms, which takes into account the part played by hail and explains also those winter thunderstorms in which there appears to be no drop formation.

The breaking drop theory was put forward as the result of work during the monsoon in India, and in the original paper it was said that there had been no opportunity to examine the electrical phenomena connected with ordinary rain or with snowstorms. That opportunity has since occurred, and has given the data for rounding off the theory so that it can now be applied to all kinds of atmospheric precipitation.

The separation of electricity on the violent disruption of a body is not confined to liquids, but occurs, probably more strongly, when solids are rapidly separated. Rudge's work on the electrification of dust clouds threw much light on this subject. When dust is blown up into the air, the dust particles are found to be highly charged. This is not an effect of frictional electricity as usually understood, because two different substances do not come into contact; for example, highly charged particles are obtained when sand consisting of pure silica is used to make a dust cloud. The effect appears to be exactly the same as in the case of the breaking drops; a violent separation of parts takes place, the substance obtains one kind of electricity while the other kind passes into the air probably in the form of large ions.

Rudge's work was undertaken to explain the high potential gradient observed in tropical regions during dust storms, but similar electrical effects are observed during blizzards in polar climates. There is physically no difference between a dust storm and a blizzard accompanied by much driven snow, and in both cases the particles of solid matter become charged in consequence of their frequent collisions. This is then the origin of electricity in snowstorms. One difficulty, however, must be faced. If the electrification takes place by collision, how does a sufficient separation of electricity take place to give a lightning flash, for this can only occur after some process has widely separated the electricity set free by the collisions? The answer is that so long as the cloud contains only snow which settles very slowly through the air, there is no thunderstorm; it is only when soft hail accompanies a snowstorm that thunder and lightning occur. As the soft hail falls through the snow flakes, electrification takes place on each collision and the falling hail carries away with it large charges of electricity. Thus the fall of the hail effects the separation of electricity which gives rise to the large electrical fields necessary for a thunderstorm. Compared with the electrical effects of a tropical thunderstorm with its heavy rainfall, the electrical effects of a snowstorm are almost insignificant, and during the polar winter, when there is no soft hail associated with the snowfall, thunder and lightning do not accompany the most violent snowstorms.

Dr. Russell in his address also gave considerable time to discussing globular or ball lightning. He came to the conclusion, which is now very generally held, that this is a real natural phenomenon with an objective existence. The chief characteristic of ball lightning may be summed up as follows:

(1) The body or ball itself, which is able to retain its individuality as it moves through the air, appears to be composed of gas or matter in some novel luminous condition.

(2) The balls appear to exist independently of any large electrical intensity, for they have been observed within closed rooms where large electrical fields are impossible, and have also

been observed to pass in and out of parallel telegraph wires.

(3) They appear to be associated directly or indirectly with large quantities of energy, for they have been observed to explode with violence, and have also been seen to fuse the overhead wire of an electrical tramway.

No satisfactory explanation of ball lightning has been offered. Dr. Russell says: "Globular lightning seems to be a brush discharge taking place at the end of a column of air of higher conductivity than the neighbouring air." He then points out some of the difficulties of this explanation, to which others can be added; in fact, there is really nothing very similar between a brush discharge and the ball of glowing gas so frequently described. The only physical phenomena yet produced in a laboratory at all approaching ball lightning is the active nitrogen studied by Lord Rayleigh. In this case we have a mass of nitrogen subjected to an electrical discharge which continues to glow for some time after it has been removed from the field. Lord Rayleigh, however, is unable to accept this explanation of ball lightning, and all that we are able to say is that active nitrogen is the nearest physical phenomenon to ball lightning yet produced in our laboratories. Ball lightning appears always to be associated with a thunderstorm, and it is possible that the intense discharge of a lightning flash can produce some atomic change in the air or rain through which the discharge passes. If this is so, the glowing matter of ball lightning may be in a state otherwise not met with in Nature.

Unusual Forms of Crystallisation of Cementite in Steel.

CEMENTITE, the carbide of iron, which confers on iron the properties of steel, exists in three principal forms in hypereutectoid steels, (1) the pseudo-dendritic form, (2) the cellular or intergranular form, and (3) the intragranular form which gives rise to the Widmannstätten structure. Pseudo-dendritic distribution arises directly from the irregular concentration of the solid solution which results on solidification. The cellular variety occurs between the grains, *i.e.* in the network of the grain junctions, while the Widmannstätten structure is caused by the precipitation of cementite in the interior of the grains themselves and shows evidence of the directive influence of the crystalline network of each grain.

A. M. Portevin has examined a sample of steel which has enabled him to make certain new observations in regard to these forms of cementite. These results were presented at the autumn meeting of the Iron and Steel Institute held recently in Italy. The sample was found in the hearth of a blast-furnace, and its exterior presented the characteristic concave facets peculiar to intergranular fracture. The grains of which it was composed were exceedingly well developed, their size being of the order of 1 cm. in transverse thickness and several centimetres in length. The specimen contained 1·22 per cent. of carbon, 1·35 of silicon, and 0·17 of phosphorus. It was, therefore, very distinctly hypereutectoid and corresponds, so far as carbon percentage is concerned, to a fairly hard cutting tool. An examination of the microstructure of this sample revealed the presence of the cellular and Widmannstätten modes of distribution of cementite, but the pseudo-dendritic form was absent.

INTRAGRANULAR CEMENTITE.

A micrographic section usually shows the cementite in needles arranged along three or four directions in each grain. This corresponds spacially with lamellæ parallel with the faces of the octahedron, and has the appearance which cementite assumes more particularly in case-hardened samples very high in carbon. In the sample examined by Portevin a different orientation of the intragranular cementite was observed. The constituent was present, not in the usual isolated rectilinear needles, but in the form of bundles of numerous very small needles, or of groups of elements crowded together. These were apparently elongated prisms analogous to the prismoids of Belaiew, grouped in masses. This is apparently the first time that intragranular cementite has been noticed with these morphological characteristics. It can, however, also be produced in steel which has been strongly case-hardened at a very high temperature and very slowly cooled. Inclusions and notably bubbles constituted centres of crystallisation around which the bundles of needles were grouped.

INTERGRANULAR CEMENTITE.

This is customarily described and represented as enveloping the grains and appearing in a section as continuous ribbon-like filaments which do not display any characteristic shape or orientation. Howe and Levy, however, have directed attention to the needle points which impinge from the cementite network into the interior of the grains, and have raised the question as to whether these take their direction in obedience to the crystallisation orientation of the adjacent grain or of that of the network itself. They have suggested that both influences manifest themselves, and that sometimes one and sometimes the other predominates. In the present sample there is no continuous network of cementite surrounding the grains. There is a grouping of this constituent along the confines of the grain joints, the variable orientation of which can sometimes be attributed to that of the intragranular elements of cementite dispersed within each grain and sometimes appears distinctly different. In other words, the two influences remarked by Howe and Levy manifest themselves. Fig. 1 represents the appearance obtained after oil-quenching at 950° C. followed by annealing at 550° C., a treatment which causes the great bulk of the pro-eutectoid cementite, and more especially the Widmannstäten cementite, to disappear. The photograph has been taken at the junction of three grains. The needles which compose the network have in one instance different directions in regard to each grain, giving the junction the appearance of the barbs of a feather, while in the two other junctions they have an almost uniform orientation. It appears that the structural elements of the network have distributed themselves along a mean direction or have assumed a direction of their own, the influences of the orientation of each grain conflicting with each other in the neighbourhood of the junction. The needles are

very short and it is difficult to ascertain their orientation with exactitude. The disturbance occasioned in the distribution of the structural elements which separate the grain junctions by the simultaneous influence of the varying orientations of each grain is thus manifest. Portevin remarks that some observers will not fail to interpret them as arising from the intervention of "amorphous material," whereas they can easily be interpreted as the resultant of two forces acting in different directions. He has observed a similar instance in the case of aluminium bronze containing 90 per cent. of copper which has been hardened and annealed. Here the intergranular elements of α separated along the grain joints have a different orientation from that of the acicular intragranular element.

FIG. 1.—Peculiar segregation of cementite at crystal boundaries. × 50.

Cementite, as is well known, is exceedingly sensitive to coalescence phenomena. The author has stimulated the coalescence of the pro-eutectoid cementite of the sample by heating it for 1·5 hours at 950° C. followed by oil-quenching, and then by one hour's annealing at 600° C. This gives darkly-etching sorbite in which the undissolved cementite appears white and is very clearly distinguishable. Under these conditions the coalescence of the cementite prismoids is shown by a rounding of the boundaries and the splitting up of the elements constituting the bundles, but in addition an agglomeration is observed which gives the cementite a pitted appearance and is misleadingly like the eutectic of white pig-iron. (See Fig. 2.) This pseudo-eutectic appearance, due to coalescence, appears to be a new observation and shows the intensity of the influence of surface tension on cementite at the above temperatures. The tension is, in this instance, an important morphological factor.

Another unusual type of occurrence of cementite in steel was described at the same meeting by Prof. Edwards and Mr. Pfeil. In this case, however, the phenomenon was observed in mild steel sheets, *i.e.* in hypo-eutectoid steels. Defects are sometimes encountered in such sheets when subjected to moderately deep stamping operations and consist of a series of corrugations in the side walls of the dish. The degree of corrugation increases on passing from the bottom to the top, and is, in all probability, due to the greater amount of cold work put upon the metal there. It was found that the microstructure of the steel consisted of two approximately equal parts: (*a*) a very coarsely crystalline layer apparently free from carbon, and (*b*) a finely crystalline layer in which no pearlite was present but the carbide was segregated at the crystal junctions in irregular nodules. A section cut from the corrugated part of the dish showed very coarse severely deformed crystals. Running round the crystal boundaries, however, was an almost continuous network of what may be termed "beaded" cementite. This constituent must have segregated from pearlite and coalesced into this form under the influence of surface tension during the annealing. Its appearance is shown in Fig. 3 at a magnification of 250 diameters. So far as the writer is aware, this type of occurrence of cementite in a mild steel has not been previously described. The authors have not proposed any explanation of how it is brought about, but are endeavouring to produce it intentionally. Clearly much work still remains to be done to explain the various forms of cementite which may and do occur in both hypo- and hyper-eutectoid steels.

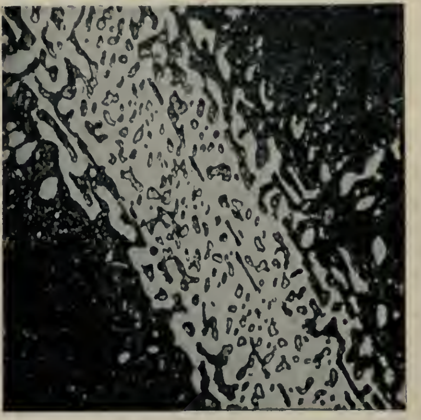

FIG. 2.—Eutectic-like appearance of cementite. × 500.

FIG. 3.—Beaded cementite at crystal boundaries of ferrite. × 250.

H. C. H. C.

Some Developments of Modern Zoology.[1]

By Prof. J. H. ASHWORTH, D.Sc., F.R.S.

ZOOLOGY has far outgrown its early boundaries when it could be defined simply as a part of natural history, and at no period has its growth been more rapid or more productive in results of scientific and practical importance than during the last two or three decades. That period has witnessed a growth of our knowledge of the living organism of the same order of importance as the progress in our knowledge of the atom. Never have investigators probed so deeply or with so much insight into the fundamental problems of the living animal; the means for observation and recording have become more delicate, and technique of all kinds more perfect, so that we can perceive details of structure and follow manifestations of activity of the organism which escaped our predecessors.

Among the notable features of zoological activity during the last twenty-five years, the amount of work on the physiology of organisms other than mammals must attract early notice in any general survey of the period. Eighty years ago Johannes Müller's physiological work was largely from the comparative point of view, but for some years after his death the comparative method fell into disuse, and the science of physiology was concerned chiefly with the mode of action of the organs of man or of animals closely related to man, the results of which have been of outstanding importance from their bearing on medicine. Interest in the more general applications of physiology was revived by Claude Bernard ("Leçons sur les phénomènes de la vie," 1878), and the appearance of Max Verworn's "General Physiology," in 1894, was in no inconsiderable measure responsible for the rapid extension of physiological methods of inquiry to the lower organisms—a development which has led to advances of fundamental importance. Many marine and freshwater organisms lend themselves more readily than the higher vertebrates to experimentation on the effects of alterations in the surrounding medium, on changes in metabolic activity, on the problems of fertilisation and early development, on the chemistry of growth and decline, and to the direct observation of the functioning of the individual organs and of the effects thereon of different kinds of stimuli. The study of these phenomena has greatly modified our interpretation of the responses of animals and has given a new impetus to the investigation of the biology and habits of animals, *i.e.* animal behaviour.

This line of work—represented in the past by notable contributions such as those by Darwin on earthworms, and by Lubbock on ants, bees, and wasps—has assumed during the last two or three decades a more intensive form, and has afforded a more adequate idea of the living organism as a working entity, and revealed the delicacy of balance which exists between structure, activity, and environment.

The penetrating light of modern investigation is being directed into the organism from its earliest stage. During the summer of 1897 Morgan discovered that the eggs of sea-urchins when placed in a 2 per cent. solution of sodium chloride in sea-water and then transferred to ordinary sea-water would undergo cleavage and give rise to larvæ, and J. Loeb's investigations in this field are familiar to all students of zoology. Artificial parthenogenesis is not restricted to the eggs of invertebrates, for Loeb and others have shown that the eggs of frogs may be made to develop by pricking them with a needle, and from such eggs frogs have been reared until they were fourteen months old. The application of the methods of micro-dissection to the eggs of sea-urchins is leading to a fuller knowledge of the constitution of the egg, of the method of penetration of the sperm, and of the nuclear and cytoplasmic phenomena accompanying maturation and fertilisation, and will no doubt be pursued with the object of arriving at a still closer analysis of the details of fertilisation.

The desire for more minute examination of developing embryos led to the more careful study of the egg-cleavage, so that in cases suitable for this method of investigation each blastomere and its products were followed throughout development, and thus the individual share of the blastomere in the cellular genesis of the various parts of the body was traced. This method had been introduced by Whitman in his thesis on Clepsine (1878), but it was not until after the classical papers of Boveri on Ascaris (1892) and E. B. Wilson on Nereis (1892) that it came into extensive use. For the next twelve or fifteen years, elaborate studies on cell-lineage formed a feature of zoological literature and afforded precise evidence on the mode of origin of the organs and tissues, especially of worms, molluscs, and ascidians. A further result of the intensive study of egg-cleavage has been to bring into prominence the distinction between soma-cells and germ-cells, which in some animals is recognisable at a very early stage, *e.g.* in Miastor at the eight-cell stage. The evidence from this and other animals exhibiting early segregation of germ-cells supports the view that there is a germ-path and a continuity of germ-cells, but the advocates of this view are constrained to admit there are many cases in which up to the present an indication of the early differentiation of the germ-cells has not been forthcoming on investigation, and that the principle cannot be held to be generally established.

A cognate line of progress which has issued from the intensive study of the egg and its development is experimental embryology—devoted to the experimental investigation of the physical and chemical conditions which underlie the transformation of the egg into embryo and adult. By altering first one and then another condition our knowledge of development has been greatly extended. By artificial separation of the blastomeres the power of adjustment and regulation during development has been investigated, and by further exploration of the nature of the egg the presence of substances foreshadowing the relative proportions and positions of future organs has been revealed in certain cases, the most striking of which is the egg of the Ascidian *Cynthia partita* (Conklin, 1905).

Progress in investigation of the egg has been

[1] From the presidential address delivered to Section D (Zoology) of the British Association at Liverpool on September 13.

paralleled by increase in our knowledge of the germ-cells, especially during their maturation into eggs and sperms, the utmost refinements of technique and observation having been brought to bear on these and on other cells. During the last thirty years, and especially during the latter half of this period, cytology has developed so rapidly that it has become one of the most important branches of modern biology. One of the landmarks in its progress was the appearance, at the end of 1896, of E. B. Wilson's book on "The Cell." A great stimulus to cytological work resulted from the rediscovery in 1900 of the principle of heredity published by Mendel in 1865, which showed that a relatively simple conception was sufficient to explain the method of inheritance in the examples chosen for his experiments, for in 1902 Sutton pointed out that an application of the facts then known as to the behaviour of the chromosomes would provide an explanation of the observed facts of Mendelian inheritance. In the same year McClung suggested that the accessory chromosome in the male germ-cells is a sex-determinant. These two papers may be taken as the starting-point of that vast series of researches which have gone far toward the elucidation of two of the great problems of biology—the structural basis of heredity and the nuclear mechanism correlated with sex. The evidence put forward by Morgan and his colleagues, resulting from their work on Drosophila, would seem to permit little possibility of doubt that factors or genes are carried in the chromosomes of the gametes, and that the behaviour of the chromosomes during maturation of the germ-cells and in fertilisation offers a valid explanation of the mode of inheritance of characters. The solution of this great riddle of biology has been arrived at through persistent observation and experiment and by critical analysis of the results from the point of view of the morphologist, the systematist, the cytologist, and the geneticist.

Among other important developments in the period, reference may be made to the great activity in investigating the finer structure of the nerve-cell and its processes. By 1891 the general anatomical relations of nerve-cells and nerve-fibres had been cleared up, largely through the brilliant work of Golgi and Cajal on the brain and spinal cord, and of von Lenhossék, Retzius, and others on the nervous system of annelids and other invertebrates. In these latter had been recognised the receptor cells, the motor or effector cells, and intermediary or internunciary cells interpolated between the receptors and effectors. In June 1891 Waldeyer put forward the neurone theory, the essence of which is that the nerve-cells are independent and that the processes of one cell, though coming into contiguous relation and interlacing with those of another cell, do not pass over into continuity. He founded his views partly upon evidence from embryological researches by His, but chiefly on results obtained from Golgi preparations and from anatomical investigations by Cajal.

The neurone theory aroused sharp controversy, and this stimulus turned many acute observers—zoologists and histologists—to the intimate study of the nerve-cell. First among the able opponents of the theory was Apáthy, whose well-known paper, published in 1897, on the conducting element of the nervous system and its topographical relations to the cells, first made known to us the presence of the neurofibrillar network in the body of the nerve-cell and the neurofibrils in the cell-processes. Apáthy held that the neurofibrillar system formed a continuous network in the central nervous system, and he propounded a new theory of the constitution of the latter, and was supported in his opposition to the neurone theory by Bethe, Nissl, and others. The controversy swung to and fro for some years, but the neurone theory—with certain modifications—seems now to have established itself as a working doctrine. The theory first enunciated as the result of morphological studies receives support from the experimental proof of a slight arrest of the nerve-impulse at the synapse between two neurones, which causes a measurable delay in the transmission.

The latest development in morphological work on nerve-elements is the investigation of the neuromotor system in the Protozoa. Sharp (1914), Yocom (1918), and Taylor (1920), working in Kofoid's laboratory, have examined this mechanism in the ciliates Diplodinium and Euplotes, and they describe and figure a mass—the neuromotorium—from which fibrils pass to the motor organs, to the sensory lip, and, in Diplodinium, to a ring round the œsophagus. The function of the apparatus is apparently not supporting or contractile, but conducting. By the application of the finest methods of microdissection, specimens of Euplotes have been operated upon while they were observed under an oil-immersion objective. Severance of the fibres destroyed co-ordination between the membranelles and the cirri, but other incisions of similar extent made without injuring the fibrillar apparatus did not impair co-ordination, and experiments on Paramæcium by Rees (1922) have yielded similar results. While the experimental evidence is as yet less conclusive than the morphological, it supports the latter in the view that the fibrils have a conducting, co-ordinating function. Progress in our knowledge of the nervous system is but one of many lines of advance in our understanding of the correlation and regulation of the component parts of the animal organism.

The ciliate Protozoa have been the subject during the last twenty years of a series of investigations of great interest, conducted with the purpose of ascertaining whether decline and death depend on inherent factors or on external conditions. While these researches have been in progress we have come to realise more fully that ciliates are by no means simple cells, and that some of them are organisms of highly complex structure. Twenty years ago Calkins succeeded in maintaining a strain of Paramæcium for twenty-three months, during which there were 742 successive divisions or generations, but the strain, which had exhibited signs of depression at intervals of about three months, finally died out, apparently from exhaustion. From this work, and the previous work of Maupas and Hertwig, the opinion became general that ciliates are able to pass through only a limited number of divisions, after which the animals weaken, become abnormal and die, and it was believed that the only way by which death could be averted was by a process of mating or conjugation involving an interchange of nuclear material between the two conjugants

and resulting in a complete reorganisation of the nuclear apparatus. Jennings has shown that conjugation is not necessarily beneficial, that the ex-conjugants vary greatly in vitality and reproductive power, and that in most cases the division rate is less than before conjugation. Woodruff has since May 1, 1907, kept under constant conditions in culture a race of Paramæcium. During the sixteen years there have been some ten thousand generations, and there seems no likelihood of or reason for the death of the race so long as proper conditions are maintained. The possibility of conjugation has been precluded by isolation of the products of division in the main line of the culture, and the conclusion is justifiable that conjugation is not necessary for the continued life of the organism. The criticism that Woodruff's stock might be a non-conjugating race was met by placing the Paramæcia, left over from the direct line of culture, under other conditions, when conjugation was found to occur. Later observations by Erdmann and Woodruff show that a reorganisation of the nuclear apparatus of Paramæcium takes place about every twenty-five to thirty days (forty to fifty generations). This process, termed endomixis (in contrast to amphimixis), seems to be a normal event in the several races of Paramæcium which Erdmann and Woodruff have examined, and it is proved to coincide with the low points or depressions in the rhythm exhibited by Paramæcium.

Enriques (1916) maintained a ciliate—*Glaucoma pyriformis*—through 2701 generations without conjugation, and almost certainly without endomixis. From a single "wild" specimen he raised a large number and found that conjugating pairs were abundant, so that the objection could not be made that this was a non-conjugating race. Enriques then began his culture with one individual, and examined the descendants morning and evening, removing each time a specimen for the succeeding culture. The number of divisions per day varied from nine to thirteen, and as there was no break in the regularity and rapidity of division, and no sort of depression, Enriques concluded that neither endomixis nor conjugation could have occurred, for these processes take some time and would have reduced considerably the rate of division. These results, especially if they are confirmed by cytological study of preserved examples, show that for Glaucoma neither conjugation nor endomixis is necessary for continued healthy existence. Hartmann's observations (1917) on the flagellate *Eudorina elegans* extend the conclusion to another class of Protozoa. He followed this flagellate through 550 generations in two and a half years. The mode of reproduction was purely asexual, and there was no depression and no nuclear reorganisation other than that following fission. The evidence seems sufficient to confirm the view that certain Protozoa, if kept under favourable conditions, can maintain their vigour and divide indefinitely, without either amphimixis or endomixis.

Child (1915) states as the result of his experiments that the rate of metabolism is highest in Paramæcium and other ciliates immediately after fission—"in other words, after fission the animals are physiologically younger than before fission." This view, that rejuvenescence occurs with each fission, derives support from the observations of Enriques and Hartmann, for no other process was found to be taking place and yet the vigour of their organisms in culture was unimpaired. If, then, fission is sufficiently frequent—that is, if the conditions for growth remain favourable—the protoplasm maintains its vigour. If through changes in the external conditions the division rate falls, the rejuvenescence at each fission may not be sufficient to balance the deterioration taking place between the less frequent divisions. Under such conditions endomixis or conjugation may occur with beneficial results in some cases, but if these processes are precluded there is apparently nothing to arrest the progressive decline or "ageing" observed by Maupas and others.

The culture of tissues outside the body is throwing new light on the conditions requisite for the multiplication and differentiation of cells. R. G. Harrison (1907) was the first to devise a successful method by which the growth of somatic cells in culture could be followed under the microscope, and he was able to demonstrate the outgrowth of nerve-fibres from the central nervous tissue of the frog. Burrows (1911), after modifying the technique, cultivated nervous tissue, heart-cells, and mesenchymatous tissue of the chick in blood-plasma and embryonic extract, and this method has become a well-established means of investigation of cell-growth, tissues from the dog, cat, rat, guinea-pig, and man having been successfully grown. One strain of connective tissue-cells (fibroblasts) from the chick has been maintained in culture in vigorous condition for more than ten years—that is, for probably some years longer than would have been the normal length of life of the cells in the fowl. Heart-cells may be grown generation after generation—all traces of the original fragment of tissue having disappeared—the cells forming a thin, rapidly growing, pulsating sheet. Drew (1922) has recently used instead of coagulated plasma a fluid medium containing calcium salts in a colloidal condition, and has obtained successful growth of various tissues from the mouse. He finds that epithelial cells when growing alone remain undifferentiated, but on the addition of connective tissue differentiation soon sets in, squamous epithelium producing keratin, mammary epithelium giving rise to acinous branching structures, and when heart-cells grow in proximity to connective tissue they exhibit typical myofibrillæ, but if the heart-cells grow apart from the connective tissue they form spindle-shaped cells without myofibrillæ.

For many lines of work in modern zoology biochemical methods are obviously essential, and the applications of physics to biology are likewise highly important—*e.g.* in studies of the form and development of organisms and of skeletal structures. Without entering into the vexed question as to whether all responses to stimuli are capable of explanation in terms of chemistry and physics, it is very evident that modern developments have led to the increasing application of chemical and physical methods to biological investigation, and consequently to a closer union between biology, chemistry, and physics. It is clear also that the association of zoology with medicine is in more than one respect becoming progressively closer. Comparative anatomy and embryology, cytology, neurology, genetics, entomology, and parasitology, all have their bearing on human welfare.

Obituary.

Prof. James Sully.

The death of Prof. James Sully, which took place in London on November 2, at eighty-one years of age, removes from among us one of the few survivors of the philosophical school for whom psychology was a mental science distinct from and yet analogous to natural science. His "Teachers' Handbook of Psychology" was for many years the standard text-book of the subject, and his treatise, "The Human Mind" the generally recognised authority on the science. Since he retired in 1903 from the Grote professorship of mind and logic at University College, London, which he had held for ten years, he has lived in retirement. To most of the present generation he is known by the honour accorded to his name in the membership lists of learned societies.

Sully's works on psychology show him still in the main under the influence of the Associationists, Mill and Bain, notwithstanding that he imparted to his subject a wide range of interest. He had no part in the revolution which has overtaken the teaching of psychology. He had studied before the days of laboratory appliances and apparatus for making practical experiments and devising mental tests. Also he was before the rise of psycho-analysis and took no part for or against the medical theories. His particular bent was towards the educational aspect of his subject and his great interest was child-study.

James Sully was born at Bridgwater on March 3, 1842. His parents were Baptists, and he was educated with the intention of preparing himself, should he receive the call, for the Baptist ministry. He went to Taunton Independent College, and afterwards to Regent's Park Baptist College, where he took the London M.A. degree with a gold medal. He then went to Germany, first to Göttingen, and afterwards to Berlin to attend the lectures of Hermann Lotze. He took a post of classical tutor in a Baptist College, but shortly afterwards resigned it and at the same time definitely abandoned the intention of taking a pastorate. Instead he took up journalism. He soon began to make his mark as an author. His book "Pessimism," 1877, gained general recognition as a work of wide and original philosophical interest. Most of his books, however, were technical treatises or handbooks for students. An "Essay on Laughter," 1902, "Italian Travel Sketches," 1912, and quite recently a volume of "Reminiscences" were his last works.

In the time of his full activity Sully lived at Hampstead, the centre of a literary circle which included many well-known names. He was an active member of Leslie Stephen's famous society for Sunday tramps. Among his close personal friends were Henry Sidgwick, Herbert Spencer, G. H. Lewes, Shadworth Hodgson, Cotter Morison, William James and Henry James, and George Meredith.

Dr. E. K. Muspratt.

The death, on September 1, of Dr. Edmund Knowles Muspratt, honorary president of the United Alkali Company Ltd., and a former Pro-Chancellor of the University of Liverpool, is deeply regretted by all who know his public work and intellectual influence.

Born in 1833, the youngest son of James Muspratt, the founder of the great alkali industry of Lancashire, Dr. Muspratt studied chemistry in early life under Liebig, becoming one of his intimate personal friends and following him when he moved from Giessen to Munich. About the year 1856 he entered his father's business, and thus was associated for the rest of his life with the alkali and acid industry of Lancashire, afterwards becoming a director and, later, chairman of the United Alkali Co.

Dr. Muspratt was one of the great citizens of Liverpool who played a leading part in the establishment, first of the University College, and later of the University of Liverpool. A man of wide culture and outlook and a sincere believer in learning and research, he did everything in his power to further the cause of higher education in Liverpool. Together with his friend, the late Sir John Brunner, he was instrumental in obtaining a charter for the new University. For many years he acted as a member of the Council, and by his influential support, wise and broad-minded advice, and generous benefactions, proved himself to be one of the greatest friends the University possessed. Amongst his benefactions may be mentioned the Laboratory of Physical Chemistry, with which his name was associated by the University.

Dr. Muspratt was widely interested in science, literature, music, the drama, politics, and public life. At Seaforth Hall, near Liverpool, his father's home (and also his own to the close of his life), he met many of the most interesting personalities of the time, including Charles Dickens, Samuel Lover, Sheridan Knowles the dramatist (who acted as his godfather), Macready, Douglas Jerrold, Mark Lemon, Miss Charlotte and Miss Susan Cushman. This tradition of culture, friendship, and hospitality was carried on by Dr. Muspratt, so that Seaforth Hall was always the home of wit, learning, and good fellowship.

Dr. Muspratt travelled a great deal in Europe (and in America). In 1917 he published a very interesting and delightful book entitled "My Life and Work."

In the England of fifty years ago there did not exist the great modern "city" Universities of Birmingham, Bristol, Leeds, Liverpool, Manchester, and Sheffield. Their creation in the face of many obstacles and difficulties has been due to the far-sighted vision and true liberalism of a comparatively small number of men. In this select company of great scholars and great English citizens, the name of Edmund Knowles Muspratt holds an honoured and distinguished place.

F. G. D.

Dr. P. W. Latham.

Dr. P. W. Latham, for twenty years Downing professor of medicine at Cambridge, who died on October 29 at Clifton, Bristol, was a notable teacher and practitioner of medicine, working ceaselessly into advanced life for the progress of his science. He died a week after the completion of his ninety-first year. The Downing professorship, entered upon in 1874, was

relinquished in 1894, and five years later Dr. Latham voluntarily resigned from the active staff of Addenbrooke's Hospital, Cambridge. Born at Wigan, in 1832, the eldest son of Dr. John Latham, he was educated there and apprenticed to his father. Later he entered the University of Glasgow, and at Gonville and Caius College, Cambridge. In the first class of the Natural Sciences Tripos of 1859 his sole companion was Henslow the botanist. In the following year he was elected to a fellowship at Downing and proceeded in due course to the degrees of M.B. and M.D. He also studied at St. Bartholomew's Hospital and in Germany.

Dr. Latham's earliest scientific interest after his return to Cambridge was tuberculosis, but in time he passed to the consideration of a wide range of pathological studies and to chemical physiology. His Croonian Lectures in 1886 showed his leaning towards these aspects of medical science; while in the Harveian Oration delivered two years later he lent his support to the advocacy of such theories as those of Koch and Metchnikoff which were rapidly leading to the formulation of modern views concerning disease and tissue reaction. Many of the problems of that time have since been solved; for example, the place of caseous tubercles in the disease complex associated with infection by tubercle bacilli; and some, like that of the transformability of organisms one into another, have been set aside or forgotten. Dr. Latham's hypothesis concerning the molecular structure of living protoplasm, further, was not acceptable; but he assisted notably in the dissemination of scientific ideas of disease and contributed in clear terms, if not prolifically, to current discussions.

By the death of Dr. Charles Proteus Steinmetz, the electrical engineering profession loses one of its most distinguished members. He was born at Breslau in 1865, and after studying at Breslau, Berlin, and Zürich, he went to America. In 1903 he was elected professor of electrical engineering at the Union University, New York. He was a voluminous author, and his books on mathematical electrical engineering are well known all over the world. He was also chief consulting engineer to the General Electric Co. of America and carried out many successful researches. We mention specially his researches on the electric strength of air and on the magnetite arc. As a mathematician he was not widely read, but he displayed great originality. He did much to help the United States to become the leading country in the world in high-tension electrical engineering. On hearing of his death the English Institution of Electrical Engineers in England cabled a message of condolence to the Institute and said that "his work lives and will continue to live."

Current Topics and Events.

MR. ROBERT HUTCHINSON, president of the National Association of British and Irish Millers, read a paper on "The Economic Basis of Wheat-growing in England" at the annual meeting of the fellows of the National Institute of Agricultural Botany on November 2. The only way, he said, of preventing the area under wheat from being further reduced was to raise the price to a profitable level. This is not impossible if a wheat is obtainable which combines with the productivity, the stiffness of straw and the resistance to disease of the best English wheats, the "strength" which puts so high a premium on the best Canadian wheats. "Strength" is the mysterious factor which determines the size, shape, and palatability of a loaf. For many years it was believed that a strong wheat could not be grown on English soils or in the moist English climate. Wheats imported for experimental purposes from Canada, Russia, Hungary and Turkey all lost their quality within a few years. But one wheat, Canadian Red Fife, has been proved to retain its strength unimpaired after 21 successive years' growth in England. Prof. R. H. Biffen, working on Mendelian lines, has proved that strength is a dominant characteristic, and by crossing Red Fife with high-yielding English wheats has already given the farmer Yeoman wheat, which without admixture of foreign wheats will yield satisfactory bread. But, in Prof. Biffen's own words, the sooner Yeoman is off the market the better, for a series of new wheats believed to combine the best characteristics of Canadian and English varieties, and adapted to different types of soils, are now growing at the Cambridge Plant Breeding Institute, and it is hoped to market the first of these through the National Institute of Agricultural Botany in the autumn of 1924. If the promise of these wheats materialises, English wheat will be lifted from the category of kinds to be bought for breadmaking only when the price is low into the category of kinds desired and essential. This change would revolutionise the financial prospects of English wheat-growing.

OF recent years the great development of agricultural education and research in Great Britain has attracted considerable attention throughout the Empire. The number of research workers spending some time at centres such as the Rothamsted Experimental Station is rapidly increasing. In the majority of cases they are sent officially by the Dominion Government concerned. A further example of this co-operation is furnished by the recent departure of Sir John Russell, Director of the Rothamsted Experimental Station, on a special mission to the Sudan. He will be associated with Dr. H. Martin Leake, Director of Agriculture for the United Provinces of India, in advising the Sudan Government on its agricultural policy. In view of the enormous possibilities for growing cotton in the Sudan, agricultural research work will be mainly concerned with cotton. The first instalment of the great irrigation scheme in the Gezira plain south of Khartoum is expected to come into operation in the autumn of 1925. At this stage 300,000 acres will be put under irrigation, of which 100,000 acres will be under cotton; but the total scheme is capable of development over an area

of 3,000,000 acres. In approaching Sir John Russell and Dr. Leake, the Sudan Government has been actuated by the desire to get the best possible advice as to the organisation and direction of the agricultural research work which should be undertaken in connexion with this project, which may ultimately produce 1,000,000 bales of cotton a year. It is hoped that the Empire Cotton Growing Corporation will co-operate with the Sudan Government in the research work to be carried out, and that this work can be co-ordinated with a general plan for research work on cotton problems to be organised throughout the British Empire.

IN the United States National Museum there is an exhibit of the original Patent Office models of the more important dynamos and arc and incandescent lamps which have been invented in America. There are also copies of the original commercial apparatus made after these models. In particular there is a series of incandescent lamps visualising chronologically the development of the Edison lamp from its inception. With this collection in view, Mr. H. Schroeder has written a "History of Electric Light," which has been published by the Smithsonian Institution. The earliest work on filament lamps dates back to 1841, when J. W. Starr, an American, did valuable experimental work and took out patents for "a metallic or carbon conductor intensely heated by the passage of electricity for the purpose of illumination." The carbon pencil operated in a barometric vacuum. An illustration is given of Edison's carbon filament lamp of October 21, 1879, which embodies the main features of the modern filament lamp. No mention is made, however, of the work of Sir Joseph Swan, who developed, between 1878 and 1880, the parchmentised cotton thread filament and ultimately the squirted thread of cellulose, which soon became the universal process. No mention is made of John Hopkinson in connexion with the three-wire system, and we do not agree with the statement on p. 54 that the use of 220-volt lamps is less economical than the use of 110-volt lamps, as they are less efficient. The savings effected in the mains by using the higher pressures have to be taken into account before a decision can be made. The excellent work done by the Germans and Americans in developing the metal filament and gas-filled lamps is well described. The output of electric lamps in the United States alone is 200 millions per annum, and is rapidly increasing.

A SOMEWHAT curious pamphlet has been sent to us by its author, Mr. J. H. Goodchild, of Muswell Hill (London: Simpkin, Marshall and Co.; price 1s.). It bears the attractive title of "Landscape and History"; but the history is that of the rocks which landscape-painters are invited to portray. Mr. Goodchild believes that the ordinary descriptions in geological text-books fail to impress on the mind the continuity of the processes that go on within a rock mass and that make it, at any moment, what it is. He appeals to the artist, with his use of colour, to help the untrained observer to appreciate what he sees. It seems to us that a good deal of description would be required to explain what the painter had striven to represent, and that the current changes and the life-history of the rocks would be much better understood after a few excursions with, say, the Geologists' Association in the field. Mr. Goodchild's views on the origin of "igneous" rocks by segregative processes among the sediments that they appear to penetrate were recently stated in NATURE (vol. 110, p. 589); but how would these processes be expressed by a painter, even if he were gifted with the brain of Leonardo da Vinci and the palette of Tintoretto? The late Mr. Brett was criticised by his fellow-craftsmen because a geologist could always feel sure as to the rocks represented in his fine and vivid pictures of coast-scenery. Mr. Goodchild probably remembers Brett; but he looks farther for an artist of almost supernatural powers, who shall enable us to "visualise"—to use a popular term—the water trickling within a headland of white chalk, or the veins of sulphide ores rusting in confinement underground. We think that we have grasped his meaning; but the pamphlet, even with the aid of its illustrations, possibly does not do full justice to the views that he wishes to propound.

THE publication of Vol. I., No. 1, of the Proceedings of the Cambridge Philosophical Society, Biological Series, is in effect the first appearance of a new biological journal, in which it is proposed to publish research work done at Cambridge in zoology, botany, and physiology. This first number does not perhaps give an adequate idea of the standard of work of this kind which is being done in the University Laboratories, as the papers are all of a rather slight character, and do not include any outstanding scientific discoveries of first-class importance. Dr. D. Klein's account of the structure and life-history of a new type of Schizogregarine parasitic on the larva of a fly is a piece of careful descriptive writing, and is well illustrated. Two papers by Mr. J. T. Saunders dealing with hydrogen ion concentration and the methods of its determination, with applications of these methods to the measurement of the carbon dioxide output of freshwater animals, are useful additions to the rapidly increasing literature on this modern method of biochemical research, and Mr. F. A. Potts's paper on the structure and function of the liver of the ship-worm (Teredo) is suggestive, though not pretending to be an account of a finished research on the subject. There is a short paper by Miss D. Eyden on the vertical distribution of *Daphne pulex* and one by Messrs. F. T. Brooks and W. C. Moore on the invasion of woody tissues by wound parasites, both of which are valuable. The number concludes with a description of a fossil alga from the Middle Cambrian by Mr. J. Walton. The journal, which is issued by the University Press, is well produced, though many will find that the excessive length of the line on the printed page causes the reader unnecessary discomfort.

FOR the benefit of private analysts and others concerned, Mr. C. B. Saunders (National Institute of Agricultural Botany, Cambridge) describes in detail

the methods of seed analysis developed and used at the Official Seed Testing Station. A critical account is given of the various methods of sample-taking and tests for purity and germination, the advantage or otherwise of each being indicated. The various classes of plants, as clovers, grasses, vegetables and cereals, require different treatment in order to obtain the best results in germination tests, questions of substratum, moisture supply and temperature needing separate consideration for each class. In some cases the methods adopted in other countries are described and the reasons given for varying the procedure at the English Official Station. The paper is entirely practical in outlook, all theoretical considerations being reserved for a future handbook on the theory and practice of seed-testing for the use of seed analysts and agricultural students.

By the generosity of Mr. S. Berkeley Smith of Karachi, the Cheltenham Public Museum has acquired on permanent loan one of the largest collections of Chinese porcelain in the provinces. The collection has arrived in 122 packing cases, weighing nearly 5 tons, and has now been arranged for exhibition. It includes a splendid twelve-fold lacquer screen; Céladon and Fanville Rose enamels; Mazarin blue jars; porcelain of the Kang Hsi period (1662-1722); a large and valuable set of plates and bowls of the Ming period (1367–1640). Next we have examples of Imperial Yellow China; the Peach Bloom type, and so-called "Indian Porcelain." The collection of Céladon ware dating back to the Sung Dynasty (960–1250) is specially important. Mr. Berkeley Smith has also sent to Cheltenham some sixty old Chinese pictures. The arrangement in the Museum is well adapted to display this important collection, on the acquisition of which Cheltenham, by the generosity of the donor, is to be warmly congratulated.

The Report of the Earthworks Committee of the Congress of Archæological Societies in union with the Society of Antiquaries is a record of steady progress. Happily, reports of destruction are few and unimportant. The value of the appointment of Mr. O. G. S. Crawford in connexion with the Ordnance Survey is shown in the identification of the sites of earthworks which have been lost sight of, and in archæological county surveys, such as that which has been set on foot in Surrey, and in survey of Welsh Hill Forts, inaugurated by the Board of Celtic Studies of the University of Wales, is fully recognised. The importance of such work is shown by the valuable discoveries made by Mr. E. Hart at Bletchingley, by Mr. Toms at Cissbury Ring, and by the honorary secretary and Mr. G. E. Cruickshank along the course of the Wansdyke, where there appear to be whole groups of settlements hitherto unrecorded. Even in a London suburb Mr. B. Barham has discovered extensive remains of an ancient dyke. Full accounts of the other activities of the Committee in excavation and exploration are given in the Report.

A book of normals of meteorological elements for the British Isles, Section IV., has just been issued by the Meteorological Office, Air Ministry, and published by H.M. Stationery Office. It has been prepared in the hope that it may prove of interest for holiday-makers, to those engaged in agriculture, to doctors and invalids. Average temperatures and the highest and lowest which may be expected, the average amount of rainfall and the number of days with rain, together with the range of variation, are given for each month of the year for 30 selected places. There are frequency tables showing for each month, and for the year, the normal number of days with hail, thunder, snow, and ground-frost. Such health resorts as Bath, Torquay, Brighton, and Eastbourne do not appear in this book of normals, but naturally there must be some limit to the number of places dealt with. An earlier book of normals, Section I., contains many places omitted in the new publication, but Section I. was more for the statistician.

Notice is given that applications for the government grant for scientific investigations for the year 1924 must be sent to the offices of the Royal Society, Burlington House, W.1 (upon forms obtainable from the Clerk to the Government Grant Committee), by, at latest, January 1 next.

A superintendent of agriculture is required by the Department of Agriculture of the Sudan Government. Particulars of the appointment can be obtained from the Inspecting Engineer to the Egyptian and Sudan Governments, Queen Anne's Chambers, Westminster, S.W.1. Applications should be marked "Superintendent of Agriculture."

A mycologist is required in connexion with the Ceylon Rubber Research Scheme. Candidates should be honours graduates of a British university with at least one year's post-graduate work in mycology or equivalent qualifications. Further information and application forms may be obtained, upon written request, from the Assistant Private Secretary (Appointments), Colonial Office, Whitehall, S.W.1.

Sir Jagadis Bose, director of the Bose Institute, Calcutta, will deliver a lecture at the Royal Society of Medicine on "Assimilation and Circulation in Plants," on Thursday, December 6, at 5.30 p.m. It will be illustrated on the epidiascope and Sir Jagadis will exhibit his apparatus in operation. The chair will be taken by the president of the Society, Sir William Hale-White.

At the annual general meeting of the Cambridge Philosophical Society held on October 29, the following officers were elected for the session 1923–24:—*President*: Mr. C. T. Heycock. *Vice-Presidents*: Prof. A. C. Seward, Dr. H. Lamb, Mr. J. Barcroft. *Treasurer*: Mr. F. A. Potts. *Secretaries*: Prof. H. F. Baker, Mr. F. W. Aston, Mr. J. Gray. *New Members of the Council*: Mr. F. P. White, Mr. E. V. Appleton, Mr. J. B. S. Haldane.

The ninety-eighth course of juvenile lectures at the Royal Institution to be delivered this Christmas by Sir William Bragg is entitled "Concerning the Nature of Things," and will deal with (1) the atoms of which things are made; (2) the nature of gases;

(3) the nature of liquids; (4), (5), and (6) the nature of crystals—(*a*) diamond; (*b*) ice and snow; (*c*) metals. The first lecture will be given on Thursday, December 27, and the succeeding ones on December 29, 1923, and January 1, 3, 5, and 8, 1924. This will be the first course of lectures to be delivered at the Royal Institution by Sir William Bragg since his appointment by the Board of Managers of the Royal Institution in June last to be Fullerian professor of chemistry and director of the Laboratory and of the Davy-Faraday Research Laboratory.

AT a meeting of the Linnean Society of New South Wales held on August 29, a proposal for the reservation of all areas in New South Wales with altitude greater than 4000 ft. was discussed, and it was resolved "that this Society desires to advocate the reservation from alienation and the more conservative administration of the Crown Lands of New South Wales on which grow the upland forests at the sources of the principal rivers for the following considerations: (1) the quality and regularity of river supply, (2) the preservation of undergrowth and timber, and (3) the preservation of the fauna and flora of scientific value; and that the terms of this resolution be conveyed to the State Government for consideration."

THE governing body of the Imperial College of Tropical Agriculture, realising the need for the provision of scientific workers and technologists if the sugar industry of the British Empire is to be developed and our dependence on foreign countries for our sugar supplies obviated, is establishing and equipping at St. Augustine, Trinidad, a model sugar factory towards which the British Sugar Machinery Manufacturers are contributing plant to the value of 20,000*l*. It is expected that the factory will be completed next year, and meanwhile the governing body has appointed Mr. E. C. Freeland to be professor of sugar technology, and Mr. P. E. Turner to be his assistant and demonstrator. Mr. C. L. Withycombe and Mr. E. E. Cheesman have been appointed demonstrators in zoology and entomology, and botany, respectively.

A COLD snap has recently occurred in many parts of England, and the *Times* of November 9 states that the frost experienced on the previous morning was the sharpest recorded for many years in the early part of November. In the screen the thermometer fell to 19° F. at Leamington, Andover, and Shoeburyness, while on the grass the radiation thermometer registered 11° at Shoeburyness. At Kew, the shade temperature fell to 22° F., which is said to be a "record" for the first ten days of November, being 2° lower than the previous "record" on November 10, 1921. At Greenwich Observatory the thermometer in the screen fell to 23° F. and the radiation thermometer registered 14° F. On November 10, 1908, the thermometer in the screen registered 22° F., which is the lowest temperature at Greenwich for the first ten days of November since 1841, a period of 82 years, while on the grass the radiation temperature was 9° F., which is the lowest radiation temperature at any time in November since 1856, when the thermometer registered 8·5° F. on November 30.

THE Optical Society of America held its eighth annual meeting at Cleveland, Ohio, on October 25, 26, and 27, the business being conducted in the physics building of the Case School of Applied Science. The meetings for the reading of papers were open to non-members, and abstracts of all papers to be read were available before the meetings. Twenty-eight papers were read, including one on the optical problems of an Art Museum, by Mr. F. A. Whiting, director of the Cleveland Museum. Prof. Michelson gave a paper on the limit of accuracy in optical measurement, and Prof. Nichols one on the spectra of incandescent oxides. Seven of the papers dealt with geometrical and general optics, eight with vision, colorimetry and photometry, and the rest with the optics of instruments and with miscellaneous optics. They originated from the Bureau of Standards, the Eastman Research Laboratory, the Research Laboratory of Bausch and Lomb, the Nela Research Laboratory, the Munsell Research Laboratory, the Research Laboratories of the American Telephone and Telegraph Co. and the Western Electric Co., from Frankland Arsenal, and from the laboratories of many of the American universities and technical schools. America is evidently alive to the necessity for research in optics.

PARTICULARS of a very complete series of adjustable resistances of the type consisting of a tube, or in some cases of a block, of rectangular section wound with a single layer of bare wire over which a sliding contact moves, are contained in a new catalogue from the Zenith Manufacturing Co. (Villiers Road, Willesden Green). The range of these has been extended to cover a variety of requirements, from compact laboratory resistances to large switchboard apparatus. Several improvements in design have been made, notably in the way in which the tubes are gripped in their holders and in the clamping on the broad metal rings at the ends, which form the terminals and zero contacts. The resistances can be connected up in a variety of ways and can be wound non-inductively when required. In some cases also it is found convenient to provide them with windings of increasing cross section, by which method some saving in space and material can be obtained, as the section of the conductor can be made to increase approximately at the same rate as the current when the slider is moved to diminish the resistance in circuit.

MESSRS. W. AND G. FOYLE, LTD., 121 Charing Cross Road, W.C.2, have just sent us a copy of the catalogue of their department No. 18, of 569 second-hand books on alchemy, magic art, curiosities, utopias, natural sciences, mining, architecture, mechanics, and their bibliography and literary history. It will repay perusal. A welcome and unusual feature is the inclusion of an index of proper names.

AMONG the announcements of the Oxford University Press is a new edition of "English Industries in the Middle Ages," by L. F. Salzman, in which

will be included much fresh material and many illustrations reproduced from medieval originals. The work will treat of mining, quarrying, building, metal-working, pottery, clothmaking, leather-working, fishing, brewing, and the control of industry.

THE latest catalogue (No. 228) of Messrs. W. Heffer and Sons, Ltd., Cambridge, is an important one. It contains upwards of 1300 titles of second-hand works classified under the following headings: scientific periodicals and transactions of scientific societies, standard scientific books, standard sets and periodicals in English, historical and general literature, foreign literature, oriental literature and journals, and addendum.

THE new announcement list of Messrs. Longmans and Co. gives particulars of the three following books which should be of interest to engineers: "Reinforced Concrete Design," by G. P. Manning, in which the subject-matter is treated from the point of view of the engineer designer. It will include the theory and practice of design as generally admitted and employed at the present day; "Applied Elasticity," by Dr. J. Prescott, written to fill a gap which has existed between the two extremes of English text-books on elasticity. Strict mathematical methods are used wherever these are not too cumbersome, and approximate methods are used to simplify the cumbersome methods; and "The Principles of Irrigation Engineering, with special reference to South Africa," by F. E. Kanthack.

MESSRS. EDWARD ARNOLD AND Co. announce the early publication of "Outlines of Palæontology," by Prof. H. H. Swinnerton, of the University College, Nottingham, in which palæontology is dealt with as a definite branch of science and not as an adjunct to stratigraphical geology, or as a mere division of zoology. The method of treatment adopted arises from the difficulty felt by students of geology and zoology and by others interested in the problems of animal life and evolution in past ages in being able to visualise all the salient characters for which a number of generic or specific names stand sufficiently clearly and completely for the purpose of making mental comparisons. This fact has been borne in mind by the author, and consequently most problems are discussed in terms of organs and structures rather than of organisms and species.

Our Astronomical Column.

TWO COMETS.—A telegram from the Cape announces that Comet Doubiago-Bernard has been observed there, and that the following orbit has been deduced:

$$\begin{aligned} T &= 1923,\ \text{Nov. } 17{\cdot}70 \\ \omega &= 254^\circ\ 32' \\ \Omega &= 227\ \ 36 \\ i &= 114\ \ 17 \\ \log q &= 9{\cdot}8976 \end{aligned}$$

The comet will return north early next year and may possibly be visible with large instruments in February and March. It travelled to nearly 70° S. Decl.

Herr Reinmuth, assistant to Prof. Max Wolf at Königstuhl, Heidelberg, detected a cometary object on October 31 at $8^h\ 44{\cdot}5^m$ local M.T. in R.A. $1^h\ 15^m\ 4^s$, N. Decl. 22° 31′. Daily motion is probably -32^{sec}, north 28′, but as the discovery was made photographically the motion may possibly have been in the reverse direction. The photographic magnitude is given as 13·0. The discovery was made in the course of the minor planet work that is regularly carried on at Königstuhl.

POLARITIES OF SUNSPOTS.—Much interest was caused at the meeting of the Royal Astronomical Society on November 9 by the reading of notes by Prof. Hale and Mr. Ellerman announcing that the Mt. Wilson observations confirmed the reversal of the polarity law for the constituent spots of double groups in the sunspots of the new sunspot cycle. The evidence now suggests that the law persists throughout one 11-year cycle, and is reversed for the following one.

Prof. Newall pointed out that this means the substitution of a 22-year cycle for solar changes, instead of the previously accepted 11-year cycle. He noted that the discovery increased the difficulty in obtaining a mechanical explanation of sunspot phenomena, since the magnetic polarities depend on the directions of the vortex motions round the spots.

THE FIREBALL OF NOVEMBER 3.—This object was observed at 6.53 P.M. at Bristol, Bodmin (Cornwall), and other places, though very few observations of a satisfactory kind have come to hand. Mr. W. F. Denning writes that the real path of the object was directed from north to south, the beginning of the luminous course of the meteor being over the region of Torquay, and the end over the English Channel about 64 miles S.S.E. of Start Point. The radiant point was at 160° + 59° near β Ursæ Majoris, from which point a bright meteor was also seen on October 14 last. This shower appears to be continuous during the last three months of the year. In any case it has been repeatedly observed from the second week of October up to the last week in December.

In the spring months of March and April the same radiant in Ursa Major is manifested with great distinctness. This long continuance or frequent repetition in meteoric radiation deserves further investigation.

SUNSPOTS AND CHANGES IN SOLAR RADIATION.—Prof. Abbot's announcement of the short-period changes in solar radiation was made several years ago. He examines (Proc. Nat. Acad. Sci., U.S.A., Oct. 1923) how far a connexion can be traced between visible changes on the solar disc and the radiation changes. His results are as follows:

1. The appearance of sunspots is accompanied by high radiation, presumably owing to the uprush of hotter matter from the interior.

2. Lower radiation generally occurs just after the central transit of spots.

3. Generally a disturbed solar surface means high radiation, a quiescent surface low radiation.

With regard to (2), he refers to Guthnick's observations of the brightness of Saturn. The fluctuations could be made to accord with the variations of radiation, on the supposition that the radiation is different in different directions, a time-correction being necessary for the difference of longitude of the earth and Saturn. It is suggested that above sunspots there are veiling rays, analogous to the coronal rays, which cause absorption of radiation.

Research Items.

THE "SHRUNKEN HEADS" OF THE JIBAROS.—In "Blood Revenge, War and Victory Feasts of the Jibaro Indians of Eastern Ecuador," by Rafael Karsten, which has been issued as Bulletin 79 of the Bureau of American Ethnology, a section deals with the methods of preparation of, and beliefs attaching to, the shrunken heads which form the war trophies of these tribes. Much attention was attracted to this subject by Sir John Bland-Sutton's lecture before the Royal Society of Medicine in November last (see the *Lancet*, November 11, 1922, p. 995; *Brit. Med. J.*, November 11, 1922, p. 932). These heads, which have been made familiar by a number of specimens in our museums, are usually about the size of an orange, the skin, with the hair attached, having been stripped from the skull by an incision at the back. Three strands of twisted red-painted cotton hang from the lips, and the whole head is dyed with charcoal. The hair, which is held to be the seat of the soul, is the most essential part of the trophy. The head is regarded as charged with supernatural power, and is never that of an enemy belonging to the same tribe as that of the slayer, with whom blood relationship might be claimed, as the process of reduction is a deadly insult to the whole tribe. Each stage of the process has its appropriate ritual. The reduction is begun by the use of three stones heated in a fire, this being obviously ceremonial, as the actual reduction is afterwards effected by the use of hot sand introduced through the opening of the neck. Heads of certain animals such as the sloth and the jaguar, are prepared by the same method and with identical ceremonial, because at one time all animals were men who fought among themselves and took one another's heads as trophies.

POLYNESIAN TYPES.—In vol. xxii., No. 2, of the Journal of the Polynesian Society, Dr. Louis R. Sullivan discusses some of the anthropometric data obtained in the Pacific by the Bayard Dominick Expedition of the Bernice Pauahi Bishop Museum of Honolulu and the American Museum of Natural History. From material collected in Samoa, Tonga, the Marquesas, and Hawaii, Dr. Sullivan has isolated two types which he calls tentatively Polynesian and Indonesian. The characteristics of the Polynesian type are light-brown skin colour, wavy hair, medium development of beard and body hair, lips of average thickness, moderately long head (cephalic index 77-78), high face, high but broad nose, and tall stature; of the Indonesian type, medium to dark-brown skin, wavy hair, scant beard and body hair, thick lips, short heads (cephalic index 81-82), stature shorter than the Polynesian, very low broad face and very low broad nose. This hitherto unsuspected Indonesian element, Dr. Sullivan thinks, explains the often-expressed opinion that the Polynesian and Indonesian are closely related types. When the Indonesian traits are removed, the Polynesian appears to be strikingly Caucasoid, and the available data seem to indicate a type intermediate between Caucasian and Mongol. On the other hand, the Indonesian type seems to be a somewhat doubtful Mongoloid diverging toward the Negrito. This type is most important as an element of the population in Tonga and the North-Western Marquesas. In addition, there is a Melanesian element in the south and west of Polynesia—in Tonga, New Zealand, and Easter Island; but Dr. Sullivan is of the opinion that Melanesian influence has been slightly exaggerated. The group exhibiting a high degree of brachycephaly (cranial index frequently 90 and over), occurring notably in Tonga, Samoa, Tahiti, and to a lesser degree in the Marquesas, to which Prof. Elliot Smith has referred as Proto-Armenoid, he regards as Polynesian with an artificially deformed head.

THE UNKNOWABLE.—It is rather curious to reflect on the completely different aspect which Spencer's theory assumes to us to-day, by reason of the change which has come over our mathematical and physical conceptions. Spencer thought of positive science as a realm of clear and transparent light surrounded by a murky realm of metaphysical darkness, and he expressed this firmly-held conviction by describing the outer darkness as the unknowable. To mathematicians and physicists to-day it is, on the contrary, these outer limits, this beyond of the world of sense-perception, of which they feel most confident that they possess sure and precise knowledge. The electron theory and the principle of relativity, which concern fundamental concepts, seem to us more secure scientifically than the sense-perceived objects of practical life. It is these which have sunk back into the mystery of the unknowable. This is not, however, the line of Mr. Santayana's thought expressed in his Herbert Spencer lecture, "The Unknowable," delivered at Oxford on October 24 and now published (Clarendon Press). For him Spencer's unknowable is a doctrine of substance, and he thinks that when the self-contradictoriness of Spencer's statement is corrected it can be brought into line as a sound Spinozistic conception. "Calling substance unknowable," he says, "is like calling a drum inaudible, for the shrewd reason that what you hear is the sound and not the drum. It is a play on words, and little better than a pun."

METABOLISM IN DIABETES.—A vast mass of data relating to the metabolism of diabetics has been accumulated since 1908 by Dr. E. P. Joslin, of Boston, working in association with Dr. F. G. Benedict, of the Nutrition Laboratory, and these are analysed and discussed in Publication 323 of the Carnegie Institution of Washington. In all, 113 patients have been examined in greater and less detail, partly in the period when the prevalent treatment was overfeeding with a low carbohydrate and high protein-fat diet, and partly since the introduction of fasting and under-nutrition as the general regime in 1914. The figures provide a great quantity of accurate measurements which will be examined with profit by those interested in the subjects.

EFFECT OF MANGANESE ON PLANT GROWTH.—Certain elements that occur only in very small amounts in plant tissues would appear to play some definite part in the economy of the plant. J. S. McHargue (*Journ. Agric. Research*, xxiv. pp. 781-794) has investigated the effect of manganese sulphate on the growth of plants in water cultures with specially purified nutrient salts, and his results indicate that at least for the plants tested, a very small quantity of manganese is essential to produce normal growth. Such plants as radish, soy bean, cow-pea, field pea, and maize do not contain sufficient manganese for growth to maturity, though some have sufficient to maintain a normal development for the first few weeks. In the latter case experiments carried on for too short a time fail to reveal the essential nature of manganese. The lack of manganese affects the production of dry matter and brings about an etiolated condition of the young leaves and buds, suggesting that the element has a function in photosynthesis and in chlorophyll formation. Experiments carried on in soil showed that manganese

sulphate applied to acid soil caused a decrease in crop, whereas if calcium carbonate was applied in addition to neutralise the acidity, increased yields were obtained. Soluble salts of manganese in acid soils may therefore be one of the causes of toxicity in such soils as exhibit toxic effects, an excess of manganese sulphate rendering a soil more or less sterile with respect to the growth of plants.

SILVER-LEAF DISEASE.—The fourth of the series of papers on this subject by Mr. F. T. Brooks and his co-workers appears in the *Journal of Pomology*, Vol. iii., No. 3, September. With financial aid from the Ministry of Agriculture, these important investigations are extending in scope, and besides experiments at Cambridge and at the John Innes Horticultural Institution, Merton, work has been done upon orchard trees at the East Malling Fruit Research Station and at Heston, Middlesex. The parasitic fungus *Stereum purpureum* is responsible for the typical silver-leaf disease, and in this fourth report, Brooks and H. H. Storey criticise Bintner's recent attempt to distinguish a false "silver-leaf" disease due to other physiological causes while pointing out that the silvery appearance, due usually to the optical effects produced by an air gap between leaf epidermis and mesophyll, may frequently arise from accidental disturbances quite unconnected with the entry of *Stereum purpureum*. The experiments now recorded show that the fungus readily infects the living wood at any exposed surface, penetrating such tissues more readily than shoots previously killed in the autoclave, in which it seems to be less active than many saprophytic moulds. A very interesting description is given of the conditions found in Pershore plums which had been infected by the disease and then "grew out" of it. On examination the dead fungus patches could be seen in the wood sharply delimited from the healthy tissues by a band of gum excreted from the tissues. The accumulation of these gum-like substances both in diseased tissues and at the surface of a healthy wound are obviously profitable subjects for further study. Brooks and Storey record many observations on natural wound protection in fruit trees and upon the usual dressings applied to protect such wounds; in their experience gas tar has been the most valuable dressing, Stockholm tar proving very disappointing as a means of protecting wounds against fungal attack.

DISSECTING A DEVONIAN FISH.—A palæontologist of our acquaintance is wont to dream of finding a palæozoic fossil with all its soft parts so beautifully preserved that he can dissect them. Our friend will be envious when he reads in the annual report of the Field Museum of Natural History (Chicago, 1923) how Dr. Erik Stensiö, the new head of the Palæontological Department of the Swedish State Museum, spent ten days at Chicago dissecting the head of a Devonian fish, Macropetalichthys. This specimen, it is said, allowed Dr. Stensiö to obtain an exact knowledge of the shape of the brain and details of the nervous and circulatory system of the head. These facts might possibly have been inferred from the petrified skeletal tissues; but the report says precisely: "The preservation of these soft parts was so perfect that they could be studied almost as well as if it were a fresh specimen." The specimen has been mounted for museum exhibition in such a way as to make a complete whole with all the dissected parts visible, and with every portion removable for close study. Zoologists will await with interest the publication of Dr. Stensiö's memoir.

FREE RADICLES.—J. B. Conant and A. W. Sloan have recently published a preliminary paper on the formation of free radicles (J. Amer. Chem. Soc., vol. 45, p. 2466). The reduction of triphenylpyrylium chloride with vanadous chloride yields a reddish substance which is insoluble in water and behaves as a free radicle. The same reducing agent reduces triphenylcarbinol in concentrated hydrochloric or sulphuric acid solution to free triphenylmethyl.

CELLULOSE DERIVATIVES.—The technology of cellulose derivatives is discussed in an article in the *Chemical Trade Journal* for October 19, which is mainly devoted to the newer ethers and esters. The preparation of cellulose butyrates is receiving attention, because by introducing more complex acid radicals it is hoped to prepare esters with useful solubility properties. The interest in the cellulose ethers has directed attention to improvements in the manufacture of diethyl sulphate, these being discussed in the article. The properties of the various esters and ethers are given.

PRESERVATION OF WOOD.—The *Chemical Trade Journal* for Oct. 5 contains an article on wood preservatives. The art of wood preservation dates back from very early times; it was practised by the Egyptians, who used antiseptic oils for the purpose. Burnett in 1838 introduced the use of zinc chloride; Wolman in 1906 patented the use of certain fluorides in conjunction with other salts, and from this date hundreds of patents on the subject have been taken out. In recent times the creosoting process has been introduced, but it confers odour and inflammability on the timber. The methods of impregnation are discussed in the article, and the results obtained from the uses of various salts are described. A note is also added on the preservation of wood pulp.

MAGNETIC DECLINATION AT KEW.—A careful detailed study by Dr. C. Chree, of the "Absolute daily range of magnetic declination at Kew Observatory, Richmond, 1858 to 1900," has just been published in the Geophysical Memoirs (vol. iii. No. 22) of the Meteorological Office. The annual variation of the daily range is examined by subdividing the year into 73 five-day periods; for each group of five days the 42-year mean daily range is given, also the largest and least values; smoothed means are given also for years of sunspot maximum and minimum. The ranges are, of course, distinctly less in minimum than in maximum sunspot years. The daily range undergoes a double oscillation in the course of a year, with maxima at the equinoxes and minima near the solstices. Again, Wolf's linear relation, $R = a + bS$, connecting the range R with the sunspot number S, is examined; a and b are found to vary quite considerably both throughout the year and from one year to another. The determination of a and b does not in itself give a measure of the degree of correlation between R and S, and this question is separately investigated. The mean correlation coefficient for the whole period is 0·86, but in the mean of the winters it is only 0·53, while there are conspicuous variations in the results for the four groups of years, each roughly comprising one sunspot period, into which the whole series is divided. Interesting frequency tables are also given (*a*) showing the distribution of ranges of different sizes, in each individual year, for the said four groups of years, for sunspot maximum and minimum years, and for each month of the year; and (*b*) showing the distribution of the hour of daily maximum and minimum declination for similar groups of the data. The paper contains a large amount of important though technical information; the results would be more readily comprehended if they had been indicated by graphs based on the numerous tables.

Palæontologists at Vienna.

THE Palæontologische Gesellschaft is an international society of palæontologists, with members belonging to several European nations, to Great Britain, and to the United States. An annual meeting was to have been held in London and Oxford during August 1914, but on account of the War and its effects it was impossible until the present year to hold a meeting outside Germany. Even now the difficulties were only overcome by the aid of the Austrian Government and the generosity of many notable Viennese, who made a meeting in their capital possible for their impoverished colleagues. Thus it was that on September 24 - September 29 a most successful gathering of 53 members and 90 interested persons took place in the University of Vienna under the presidency of Prof. Othenio Abel.

The non-Austrian members included Prof. Wiman of Uppsala, Professors Van Bemmelen and Versluys from Holland, Baron Fejerváry of Buda-Pest, Prof. Pompeckj of Berlin, with 36 German colleagues, Dr. F. A. Bather of the British Museum, and representatives of Czechoslovakia and Jugoslavia.

The congress was honoured in having its session opened in the Festival Hall of the University by the President of the Austrian Republic, Dr. Hainisch, supported by his Vice-chancellor, Dr. F. Frank, Dr. Maurus representing the Minister of Education, and the Rector of the University, Prof. C. Diener. The large gathering listened to an address by Prof. Pompeckj on "The Beginnings of Life," which, in his opinion, took place on the land and not in the sea. Here may be mentioned the dinner in the Rathaus, also attended by the President of the Republic, when speeches of welcome were made by the president of the society and the Deputy-Mayor. The honour of returning thanks on behalf of the foreigners was allotted to Dr. Bather, who dwelt on the power of scientific intercourse to unite the nations, and showed how the advance of science, and notably of palæontology, was retarded by the vexatious barriers still erected by politicians.

The purely scientific programme included the following papers. Baron Fejerváry: The origin of the præ-hallux and the Cheiropterygium theory in the light of palæobiological research; C. Wiman: on some flying Saurians; F. A. Bather: Cothurnocystis, a study in habits and evolution, also Stephanocrinus, a study of convergence; R. Richter: Convergence among Trilobites; H. Schmidt: The development of the Ammonoidea in the Carboniferous; P. Kessler: Nautilids with incomplete septa, which led to a discussion on their mode of life; R. Kubarth: Researches on recent and fossil conifer woods; O. Abel: The first find of a Tetrapod track in the Alpine Trias. The chief interest of the meeting, however, centred in the so-called Drachenhöhle at Mixnitz on the Mur in Steiermark. In this cavern, 1000 metres above the sea, there has been found a remarkable series of cave-bears in all stages of skeletal growth, as well as the remains of smaller mammals associated with them. These have been studied by Prof. Abel and his assistants K. Ehrenberg, O. Antonius, A. Bachofen-Echt, and others. These all described their particular researches, and Prof. Abel in a public lecture drew a vivid picture of the animal life of the "Dragon's Cave."

Opportunity was given to the members to visit Schönbrunn, where the menagerie still contains a fine representation of wild Bovidæ, and the Geological and Mineralogical galleries of the Natural History Museum. An afternoon was devoted to an excursion to the Pallerstein in the Wiener Wald, where the Eocene flysch preserves most curious markings, for the most part of annelid origin. At the close of the meeting 70 members visited the Mixnitz cave, and after spending four hours in the study of its mysteries, were refreshed by a delightful supper and entranced by Styrian folk-songs sung by a choir of local ladies. Fifteen managed on the following day to ascend the Sonnwendstein near Semmering under the guidance of Prof. Kober.

The following have been elected officers for the ensuing year. President: O. Abel (Vienna); Vice-Presidents: O. Jaekel (Greifswald) and E. Stromer (Munich); Secretaries: O. Antonius (Vienna), R. Richter (Frankfort); Treasurer: P. G. Krause (Berlin). New members of Council are F. A. Bather (London) and W. Janensch (Berlin).

The warmest thanks of all who enjoyed this inspiriting gathering are due to Prof. Abel, who, with his colleagues Dr. K. Ehrenberg and Dr. O. Antonius, saw to all the arrangements. Nor should there be forgotten the fine reconstruction of the mammoth made under their direction by the artist Franz Roubal, or the members' badge based thereon by Prof. R. Marschall. The "enkel Bier-abend," where some found a more intimate hospitality in Dr. and Mrs. Abel's home, was a characteristic and delightful feature. But it is more fitting to end with mention of Prof. Abel's "Palæobiologischer Lehrapparat," where he has accumulated a most interesting series of fossils illustrating what one may term their natural history. Nowhere else have we seen this idea so consistently carried out. This room, like the meeting as a whole, was a constant reminder that neither fossils nor those who study them need be dull and lifeless creatures.

Deterioration of Structures in the Sea.[1]

THE investigations on the deterioration of structures of metal, concrete, and timber exposed to the action of sea-water which are being carried out under the direction of a committee of the Institution of Civil Engineers have already formed the subject of two interim reports (see NATURE, October 21, 1920, p. 235, and December 30, 1922, p. 878). The third report, which has just been issued, records progress along several very different lines of research, although, since the phenomena with which they are concerned are slow in developing, conclusive results are not to be looked for in a short space of time.

That part of the work of the committee which deals with the corrosion of metals is the subject of several sections of the report. A full account is given of the arrangements devised for exposing test bars of various types of iron and steel to the action of the sea. The bars, prepared under the supervision of Sir Robert Hadfield and Dr. J. N. Friend, have been despatched to Plymouth, Halifax, Colombo, and Auckland, and reports are given from the engineers in charge at these places describing the methods used for fixing them in position. Groups of bars are to be exposed for five, ten, and fifteen

[1] "The Deterioration of Structures in Sea-Water." Third (Interim) Report of the Committee of the Institution of Civil Engineers. Edited by P. M. Crosthwaite and G. R. Redgrave. Pp. 79. Department of Scientific and Industrial Research (H.M. Stationery Office). Price 3s.

years respectively, after which they will be returned for examination and weighing.

Meanwhile, laboratory work on the same subject is being continued, and the present report includes a short but important communication from Dr. Friend on the influence of strain on the corrodibility of iron and steel, which is of more than merely technical interest. It has long been known that iron, after being subjected to strain, is particularly liable to corrosion, but little exact investigation has been done on the subject. Dr. Friend has carried out a series of experiments on sections cut from bars that had been broken in the tensile tests carried out for the committee. These bars represented seven kinds of wrought-iron and steel, the chemical and physical properties of which had been exactly determined, as well as the degree of strain as measured by the amount of elongation at the points at which the sections were cut. The specimens, isolated on paraffin blocks to prevent any galvanic action, were exposed for a whole year to alternate wetting and drying by tap water in a siphon tank, and the amount of corrosion determined by weighing. The result was, briefly, to show no difference in corrosion between strained and unstrained sections except in the case of a nickel steel (36 per cent. Ni) and less clearly in a chromium steel (13 per cent. Cr). Both these steels, and especially the latter, were very resistant to corrosion, but the percentage difference between strained and unstrained portions is described as "extraordinarily great, resembling in magnitude that observed when strained metals are subjected to acid attack." Dr. Friend is careful to point out that the uniform rates of corrosion in the other irons and steels are not to be taken as contradicting practical experience. In the tests electrolytic action was carefully excluded, but in practice strained and unstrained portions of the metal would be in continuous contact and the difference of potential so produced might well account for the localised and severe corrosion often observed.

A very different field of work is that concerned with the destruction of timber by animal pests, of which the most important are the various kinds of "shipworms" commonly referred to as Teredo. Prof. George Barger reports on experiments in treating wood with various preservatives. The test pieces, after impregnation with the poisonous solutions, were "baited" by attaching a veneer of untreated wood, and were exposed to attack by Teredo at Lowestoft. The most remarkable results were obtained with an arsenic compound, phenarsazine, known in poison-gas warfare under the names "D.M." and "Adamsite." In 1 per cent. alcoholic solution this compound entirely prevented the Teredos from penetrating the test-blocks, although they were numerous in the veneer; even in a dilution of 0·1 per cent. the protection was all but complete.

Mr. C. R. Harington carried out at the Laboratory of the Marine Biological Association at Plymouth some very interesting experiments on the larval development of Teredo. The free-swimming larvæ were kept alive for a fortnight, but attempts to find a suitable food for them failed, and, although they were attracted to and settled on shavings of wood, it was not possible to observe their boring. An important and novel result was the discovery of the manner in which they are attracted to the wood. It was found that alcohol and ether extract from wood a substance which has a strong chemotropic action on the larvæ. Photographs and diagrams are given to show how the larvæ congregate round a small particle of the extract when it is placed in the dish in which they are swimming. Experiments were then made with solutions of various pure substances in capillary glass tubes closed at one end and placed in sea water containing the larvæ. Of the substances tested in this way, malic acid was the only one showing a very pronounced attraction. Whether this is actually the attractive substance occurring in wood, however, has not yet been ascertained.

It is to be noted that neither Prof. Barger nor Mr. Harington mentions by name the species of Teredo used in their experiments, and the possibility that the Lowestoft Teredo may be different from that found at Plymouth is not even referred to. Yet the zoological no less than the physical or chemical data of the experiments deserve to be determined with all possible precision. Closely allied species of animals often differ widely in their physiological reactions. One man's meat is another man's poison, and, although no species of Teredo is likely to grow fat on phenarsazine, it cannot be assumed without trial that a poison efficient at Lowestoft would be equally so at Colombo or even at Plymouth.

A contribution of a very different type is a "Report on Boring Organisms in various Waters" by Mr. J. E. Cunningham of Sydney. It contains a series of statements of the most amazing kind regarding the natural history of Teredo. As an example we may quote the assertion "that full-grown worms will leave a piece of timber and enter another." It is a great pity that the committee should have thought fit to include a report of this character in an official publication.

Invention and Research in Mechanical Engineering.

MANY workers in applied science have an interest in patents and patent law, and to such the remarks made by Sir John Dewrance in his presidential address to the Institution of Mechanical Engineers on October 19 will be of value. Patents and research have occupied a good deal of the president's working life, and consequently they were dealt with very comprehensively in his address.

Some of the large engineering concerns of to-day were started to work patented inventions, but if we look back it is difficult to find very many of these inventions that became the standard productions of the industry when the monopoly expired. It has become increasingly difficult to invent anything that has not been foreshadowed in some previous publication. Patents have gradually become of less importance in mechanical engineering.

Sir John Dewrance has taken out 114 patents; when a definite object is desired, the practice of his firm has been to search its own records to see what has been done before; the Patent Office records are then consulted. Various methods are then evolved and discussed; some of these get no further, whilst others are made, tried, altered, and improved, and the result is exactly what has been felt ought to have been done without all the trouble taken. If the article finds a ready sale, an infringer may adopt the converse process by searching the Patent Office and other records, and producing what is called a mosaic anticipation—one detail is shown in one patent, another in a second, and so on. It has always seemed to Sir John to be unfair that documents should be evidence of anticipation; evidence should be of prior use, and the extent of that use should be sufficient to prevent fraudulent evidence being accepted. The object of a patent specification is that the industry

may be informed exactly how to carry out the invention after the monopoly has expired. If the industry carry out the invention as described, there is ample evidence of use, but in the large proportion of cases the public do not wish to avail themselves of the privilege. Cases are known of specifications being quoted forty years after being filed, during which period there had been no use in accordance with the specification. If the industry has not exercised the privilege of use, and the subsequent inventor has eliminated the defects that prevented the previous patent from coming into use, surely he has good ground for claiming that he has produced a new manner of manufacture.

No less than 16,172 patents were sealed in 1907. Of these 677 were paid up for the sixteenth year in 1922, *i.e.* 4·2 per cent. Of these 677 patents, excluding ordnance, less than 100 related to mechanical engineering. When we realise that only one mechanical patent in 10,000 is worth exploiting, and the industry has to bear the cost in brain power, fees, etc., it seems probable that it would be cheaper for the industry to associate to test designs such as is now being done for research, standardisation, and the other associated activities.

The chief difference between research and invention is that, when conducted by an association of the industry, the results belong to the industry, but the rights of a patented invention belong temporarily to the patentee. The mind of an inventor is liable to exhibit a preference for those designs which may become subject-matter for a patent. The mind of the research worker should be quite free from such restraint, the only object being the best possible result suitable for general adoption and, in some cases, standardisation. It is remarkable that when fixing standards it is seldom, if ever, the British Engineering Standards Committee has wished to adopt an appliance that has been the subject of a patent. The activities of research associations, learned societies, technical colleges, and the British Engineering Standards Association will undoubtedly increase and perform a great many of the duties that in the past were performed by patentees.

Sir John gave an account of the various bodies which are promoting research, and said that it would take too long to give a complete list of the researches in progress—researches that no single firm could carry out wisely or successfully. Such researches can be undertaken only by associations, which those interested ought to assist in every way possible for the benefit of the industry as a whole. Every one who uses knowledge successfully ought to do something to obtain further new knowledge. Sir John desired to impress upon his audience the increasing confidence and hope that, in the future, research will help us to surmount our difficulties. It is of importance that all research workers should realise that by "team" work they must justify and increase this confidence. The nation is watching the result, and critics are not wanting—some are useful and some take a narrow view. We have now opportunities that we never had before, and with British determination we can confidently expect great developments in the future, far exceeding those that have been accomplished in the past.

The New Chemistry.[1]

By Dr. E. F. ARMSTRONG, F.R.S.

IT can be argued that we have just entered on a new stage in chemical investigation. Labours in the main of an analytic type have enabled the exact structure of all but a very few substances to be established: the results have been confirmed by synthetic operations, and most compounds have been built up step by step from their elements. Whilst physicists of the modern school, by a series of most brilliant researches, have learnt much about the nature of the atom, the chemist is now concerned with the behaviour of the molecule. This has entailed the recognition that he has not only to deal with crystals and relatively simple molecules in solution but also to consider actions taking place at the surface of colloid aggregates. As it is probable that the bulk of the reactions in the plant and animal cell are of this nature, their importance will be at once conceded. Further, it must be realised that there is evidence that molecules in solution have a definite space orientation at such colloid surfaces, and indeed according to the work of Hardy at surfaces in general.

According to the accepted space lattice theory of matter, there is a definite attraction causing adhesion between each layer of molecules, and consequently at a surface, say of a piece of glass, there are unsatisfied forces or valencies. At first when a drop of a lubricant is placed on such a surface nothing happens, but when two surfaces of glass are moved over one another the molecules of the lubricant become arranged according to a definite pattern. The chemist to-day, in seeking to explain chemical action, has to realise that this takes place in many instances between aggregates of molecules and at the surface of such aggregates, and not between single simple molecules in solution such as his equations postulate and the ionic theory in its original form demands.

The first fact which has emerged from the detailed study of chemical action at a surface is that the action is not one of the so-called first order in which the same fraction of the reacting substance undergoes changes in successive equal intervals of time—a change expressed graphically by a logarithmic curve. When proper and sufficient care is taken to keep the surface active, the rate of change is uniform, provided that the changing substance is present at the surface in sufficient quantity. These facts are in accord with the hypothesis that action is preceded by the formation of an additive unstable complex which breaks down in all possible ways, that is, into a variety of components, practically as fast as it is formed. The problem of the source of the energy necessary to effect this is not without interest, but it is common to all chemical reactions and its discussion may safely be left to the exponents of the quantum and other theories.

Such actions as we are considering are known as catalytic, the change being effected by virtue of the activity of the catalyst surface, the only other agent involved in practically all cases both in the living cell and the test tube being water. It is now recognised that the water molecule can undergo rupture in two ways, either being distributed upon a single molecule, which is thereby resolved into two others:

$$A.O.B + H.OH = A.OH + B.OH,$$

or divided between two molecules in such manner that whilst the one is oxidised the other is reduced:

$$A + 2H.OH + B = AO + H_2O + BH_2.$$

Entirely different classes of catalysts bring about the two actions, but all are classed as enzymes when

[1] Synopsis of an address delivered to the South Wales Section of the Society of Chemical Industry on November 8.

concerned with changes which take place in the cell. Such enzymes as are well known are highly specific and selective, a different enzyme being required for each class of compound.

Armed with the knowledge of the fundamentals of chemical action in the cell, the time is ripe for the chemist to ascertain the inner meaning of phenomena which the biologist can investigate only by the recording of external visual characteristics. As a case in point, the coloration of flowers and its inheritance may be cited. There is much in favour of the view that flower colours, whether anthocyans or belonging to other groups, are the product of the interaction of two factors, an oxidase and a colourless precursor of the pigment. The absence of either factor means failure to develop colour by the plant, that is, white flowers, and there may also be a third factor present which prevents action taking place between oxidase and leucobase.

If proper combination of effort between the biologist and chemist can be ensured, numerous baffling problems, many of which are of far-reaching economic importance, can be attacked. As illustrating one such, in which that all-essential factor quality is concerned, the puzzling fact well known to agriculturists may be mentioned, that one pasture can fatten stock whereas another is of very little value for this purpose.

University and Educational Intelligence.

CAMBRIDGE.—Dr. Horace Lamb, Trinity College, has been appointed to give the first Rouse Ball lecture on some subject related to mathematical science.

Mr. M. H. A. Newman has been elected a fellow of St. John's College.

It is proposed that the sum of 3030*l.* bequeathed to the University by Mrs. Amy Price Read, shall be devoted to the establishment of a research scholarship similar to the Allen scholarship. In the years when the Allen scholarship is confined to literary subjects of study the Amy Price Read scholarship is to be confined to scientific subjects and vice versa. The scholarship would be open to women students who have been admitted to the titles of degrees on the same terms as to graduates of the University.

LONDON.—The degree of *Ph.D. in Science* has been conferred on Fanny Lowater (Imperial College—Royal College of Science) for a thesis entitled "A Study of the Band Spectrum of Titanium Oxide."

THE use of wireless for university extension work has progressed rapidly in America. Of fifty-seven universities and colleges possessing broadcasting stations at least two—the University of Michigan and Michigan Agricultural College—have organised regular radio extension courses, and the National Radio Chamber of Commerce is developing a plan for establishing other similar courses.

THE Council of Armstrong College, Newcastle-on-Tyne, has appointed Prof. A. S. Ferguson, Ontario, to the chair of philosophy rendered vacant by the departure of Prof. R. F. A. Hoernlé to the University of the Witwatersrand, Johannesburg. Prof. Ferguson is a student of St. Andrews and Oxford, and has contributed articles on Plato to various periodicals.

THE directors of the Leplay House educational visits abroad are taking a group of their members, and others who care to join, to Spain for the Christmas vacation, leaving London December 22, and returning January 6, or with extension January 13. Modern social, economic, and political problems will be touched upon both from the point of view of the peasant life and the city life of to-day. A course of lectures will be included in the programme. Full particulars can be obtained from Miss Margaret Tatton, Leplay House, 65 Belgrave Road, Westminster, S.W.1.

A DEPARTMENT of Geology, Mining, and Metallurgy has been established by the Benares Hindu University under the direction of Prof. N. P. Gandhi. This development was made possible by a gift of Rs. 200,000 by the Maharaja of Jodhpur, who has also endowed a Jodhpur-Hardinge chair of technology. At present the staff of the department comprises two professors—of mining and metallurgy and of geology—an assistant professor of assaying and two demonstrators.

Two travelling fellowships open to women graduates of Great Britain, each of the value of 1000 dollars, are being offered through the British Federation of University Women, 92 Victoria Street, S.W.1. One is offered by the American University Women, to enable the holder to carry on a year's research in any foreign country she may choose. The other, the Rose Sidgwick Memorial fellowship, also endowed by the Americans, offers the same amount to enable a British woman graduate to carry on a year's research or advanced work at an American university, the choice of the university being left to the holder.

IN an article on the Rhodes Scholarships in the *Empire Review* for October, Mr. Ian D. Colvin celebrates the "coming of age" of the great scheme founded in 1902. He remarks that it is yet too young for us to judge of its fruits, as scholars have not yet had time to reach maturity and make their name in the world: he accordingly confines himself to an appreciation of the character of the founder and his aims in founding the scholarships, and a description of the administration of the trust. President Frank Aydelotte, of Swarthmore College, the American Secretary to the Rhodes trustees, is less cautious, having attempted in "Oxford of To-day" an estimate of the influence exerted by the American Rhodes scholars. In the first place he points out that they have, almost to a man, returned to America, and there is a consensus of opinion that they go back better Americans for their Oxford experience. Only one of them has become a British subject. More than a third of them are engaged in educational work, and of these many are already college professors, deans, and presidents. "Perhaps there is no career in the United States at the present time which represents more accurately what Rhodes thought of as public life, no career which offers a better opportunity to influence public opinion than that of professor or administrative officer in one of our American colleges or universities." One of them is United States Commissioner of Education, and as head of the Washington Bureau undoubtedly exercises very great influence. No account such as President Aydelotte has given for the Americans seems to have been published regarding the careers after leaving Oxford of the other Rhodes scholars. It is known, however, that an occupational census of those who were elected to scholarships up to 1916 gave the following percentages: educational work 32, law 25, business and industry 11, administration and other government service 8, medicine 7, ministers of religion 4, farming 3, social and philanthropic work $1\frac{1}{2}$, journalism and publishing $1\frac{1}{2}$, engineering and mining $1\frac{1}{2}$, other occupations 5.

Societies and Academies.

LONDON.

Royal Society, November 8.—A. S. **Parkes**: Studies on the sex-ratio and related phenomena—fœtal retrogression in mice. By means of *corpora lutea* counts it was found that in mice the average amount of fœtal mortality leading to retrogression was 10·8 per 100 normal fœtuses. Daniel and King have shown for mice and rats respectively that the does may become pregnant at the œstrus period which follows within twenty-four hours after parturition, and that the gestation period of the second litter is prolonged in some cases as much as ten days. This abnormal prolongation of the embryonic stages, which is due to inhibited implantation in the uterine *mucosa*, can be used experimentally to determine the effect of unusually adverse conditions upon embryonic and fœtal mortality. Where the previous young were suckled less than six days, the amount of mortality rose to 17·6 per 100 normal fœtuses, while in prolonged gestations resulting from continued suckling of previous young, the amount of mortality was further increased to 23·1. The sex-ratio of young born in these two classes was respectively 80·4 and 62·1 males per 100 females. Since the normal sex-ratio of mice is not far from equality, this inverse correlation between the amount of fœtal mortality and the sex-ratio of the surviving fœtuses suggests that mortality during gestation falls preponderatingly upon the males.—R. A. **Fisher**: The influence of rainfall on the yield of wheat. The Rothamsted data for rainfall and wheat yields extend to 1854; these data have been utilised to calculate the average effect on the yield of rain at different periods of the harvest year, for plots under 13 different manurial treatments. An extension of the method of partial correlation, applicable when the number of independent variates is very large and can be arranged in a continuous series, is used. The several plots show marked differences in their response to rain, showing that it is not impossible for the farmer to adapt his manurial treatment to a wet or dry season. A large part of the differences may be ascribed to the effects of loss of soil nitrates by percolation; other effects not susceptible to this explanation, and not hitherto anticipated, include the losses on the highly nitrogenous plots due to late summer rain. The residual value of artificial nitrogenous manures appears from these results to be considerably greater than has been thought.—D. **Thursby-Pelham**: The placentation of *Hyrax Capensis*. The early development of Hyrax is unknown, but there is no embedding of the blastocyst which undergoes its development in the uterine lumen. The maternal epithelium is destroyed early by the trophoblast on all sides. The trophoblast is differentiated into two cytotrophoblastic layers:—(1) basal phagocytic layer (basal trophoblast); (2) cellular network enclosing lacunæ of maternal blood (inner trophoblast). The placentation throws little light on the affinities of Hyrax. While it agrees with the placenta of rodents in being hæmochorial, it differs in its zonary form and the detailed character of its trophoblast. Superficially it bears some resemblance to the placenta of Elephas in zonary arrangement and great complexity of allantoic villi, but in Hyrax there is no syncytial layer of maternal tissue surrounding the villi as in Elephas. Our present knowledge of the placentation of Hyrax tends to emphasise the isolated position the order occupies among Eutheria.

Physical Society, October 26.—Dr. Alexander Russell in the chair.—S. H. **Piper** and E. N. **Grindley**: The fine structure of some sodium salts of the fatty acids in soap curds. X-ray photographs of certain sodium salts of the fatty acids (soap curds) show lines due to reflections from planes with very wide spacings of the order 40 Å.U. These planar spacings increase uniformly with the number of CH_2 groups in the molecule, indicating an effective length of 1·25 Å.U. for the CH_2 group. These and other lines can be accounted for by assuming that the curds are in the smectic state described by Friedel.—E. A. **Owen** and G. D. **Preston**: X-ray analysis of solid solutions. The atomic structure of solid solutions of copper-aluminium, aluminium-magnesium, and copper-nickel has been examined by the X-ray spectrometer. In each case it was found that the solute atom replaces an atom in the lattice of the solvent, the substitution being accompanied by a distortion of the lattice. The eutectic alloy of aluminium and copper consists of a mixture of two distinct substances with different space lattices, one being $CuAl_2$ and the other a substance the space lattice of which cannot be distinguished from that of pure aluminium. The intermetallic compound $CuAl_2$ possesses a simple tetragonal lattice of side 4·28 Å.U. and axial ratio 0·562, the copper atoms being at the corners and the aluminium atoms at the centres of the four small faces. The atomic structure of the compound CuAl resembles that of a solid solution of aluminium in copper, but the distortion is considerably greater. The material has a face centred trigonal lattice of side 3·89 Å.U. and an angle between the axes of 94·6°, the 111 planes being composed alternately of aluminium and copper atoms.—H. **Chatley**: Cohesion. The consequences are discussed of assuming that the alternately positive and negative atoms in a crystal may be treated as doublets attracting according to an inverse fourth-power law, while the electron fields surrounding the atomic nuclei repel according to an inverse tenth-power law. The numerical results agree fairly well with the facts as regards the strain which produces rupture in solids, and as regards the rate of change of compressibility with compression in liquids.

Linnean Society, November 1.—Dr. A. B. Rendle, president, in the chair.—S. **Garside**: The forms of *Hypoxis stellata*, Linn. f., a South African species of Amaryllidaceæ. Four varieties are distinguished, one of these as yet undescribed. In each case the varieties have constant vegetative characters, but the flowers show a considerable range of colour variation of a "continuous" kind. Important cytological characters of the upper epidermis of the perianth lobes were described, with particular reference to the remarkable iridescent areas which occur in some varieties. Habitat may considerably influence the size of the plant, but the varietal characters remain constant.—H. A. **Baylis**: The host-distribution of parasitic thread-worms (nematodes). The nematodes parasitic in vertebrates show great variety in the extent to which they are limited to particular hosts. They may be divided broadly into a section with more or less strict "specificity" and a section with members occurring in various hosts, often of quite distantly related groups. Many of the latter have an intermediate host (commonly an invertebrate) during their earlier phases, and these forms, being introduced into the final host at a more advanced stage than those which have a direct development, may be better able to adapt themselves to a variety of final hosts. Among forms with a direct development, those which show the strictest specificity are probably the most specialised, this being often correlated with specialisation, in habits

or otherwise, of the hosts, while those which have a wide range have retained a primitive adaptability.—W. N. **Edwards**: On the cuticular structure of the Devonian plant Psilophyton. Specimens of *Psilophyton princeps*, Dawson, from Gaspé (New Brunswick) in which the cuticle is preserved, show that as in the early land plants of the Rhynie Chert the stem is provided with stomata. These resemble in size and distribution the stomata of Asteroxylon but have cuticle thickenings. No stomata were seen on the highly cuticularised spines, but these spines do not resemble intumescences of Rhynia, and Psilophyton is probably nearer to Asteroxylon.

Aristotelian Society, November 5.—Prof. T. Percy Nunn, president, in the chair.—T. P. **Nunn**: (Presidential address) Scientific objects and common-sense things. The greatest achievement of the physical sciences is generally held to be the discovery, behind the veil of common-sense things and observable events, of a world of scientific objects and unobservable events. The primary qualities of common-sense things are transferred without difficulty to scientific objects. Size, mass, and motion, for example, belong to an electron in the same sense in which they belong to a flying bullet or to a planet. Their materiality being thus assumed, these objects have constantly increased their hold upon the scientific mind. The philosophical question involved in this concept is whether objects can exist which only possess the primary qualities of common-sense things and have none of their secondary qualities. To resolve this problem we must have a satisfactory theory of the common-sense thing. Such a theory is that a thing is a structure embracing and actually consisting of all the sense-data which common-sense regards as qualities of the thing and are presented to any percipient at any time or place. Unless this doctrine is hopelessly wrong, tne pretension that scientific objects are the reality of which the common-sense world is but the appearance, must be entirely abandoned. The real achievement of science is not to have disclosed any reality behind the veil of sensible things, but to have greatly extended and deepened and rationalised the scheme of the world revealed in perception.

Ipswich.

Prehistoric Society of East Anglia (Autumn London meeting), October 10.—H. **Bury** (Presidential address): The distribution of palæoliths in the Hampshire basin, with special reference to a "palæolithic horizon" separating levels at which implements are common from those in which they are extremely rare. This horizon indicates the highest altitude reached by the rivers in palæolithic times; the implements found at higher levels were buried during glacial conditions, when the normal drainage was temporarily obliterated. The differences in the level of the horizon in the Hampshire, Thames, and Somme Basins respectively (150 to 130 feet) are due to changes in the position of the river mouths, and not to local warpings of the earth's crust. There is clear evidence from the New Forest and Bournemouth Plateaux that the river fell and rose again in Lower Palæolithic times, the total range of movement (100 feet) agreeing exactly with the change from the third to the first terrace of the Somme, which Commont attributes to the Chellean period. But the English evidence makes it clear that tne subsequent rise of the river (in or after Acheulean times) was much higher than Commont admits, and reached the extreme level of the Palæolithic horizon. The corresponding sea-level is more difficult to ascertain, but evidence from the Isle of Wight points to 120 feet O.D.—M. C. **Burkitt**: The discovery in northern Spain of an industry which appears to be transitional between those of the late palæolithic and the opening of the neolithic ages. Masses of shells cemented to the roofs of certain caves on the coast of the Asturias are accompanied by a stone hand-pick made from a flat pebble fluted to a point, the butt and under side being unworked. This implement is found with the accompanying shell middens to overlay deposits containing the typical harpoons of the Azilian industry, and is evidently earlier than the early neolithic stage.—L. **Armstrong**: The excavations undertaken at Grimes' Graves, Norfolk, during the past summer. A survey of the site was made in 1922 to ascertain the level at which the floor-stone flint worked by the prehistoric miners outcropped in the adjoining valley. This season, aided by a grant from the Percy Sladen Memorial Trust, excavations were made with the view of determining whether a phase of mining could be traced on the hill slope earlier than the large galleried pits sunk from the top of the adjoining hill. A type of flint mine was discovered in which the radiating galleries were absent; descent was made by aid of rough steps left in the chalk; these were excavated by small hand-picks of splintered bone, which in one case was human. No trace of these pits can be detected on the surface; they are filled with an extremely compact deposit of chalk. Thus they are in direct contrast to the conditions in the long-known pits of Grimes' Graves, which seems to indicate a more ancient period of working. A glacial disturbance of the sides of the valley has thrust up a series of blocks of the flint towards the surface, which would probably attract the attention of the flint hunters.—A. G. **Wade**: Ancient flint-mines at Stoke Down, Sussex (*v.* Nature, October 20, p. 597).

Paris.

Academy of Sciences, October 22.—M. Albin Haller in the chair.—H. **Deslandres**: An equatorial of a new type, named the table equatorial, intended especially for researches in physical astronomy.—A. **Châtelet**: The properties of finite Abelian groups.—A. **Bloch**: The paratactic circles and the cyclid of Dupin.—M. **Hadamard**: Remarks on the preceding communication.—Maurice **Gevrey**: Some properties of quasi-analytical functions of one or more variables.—Harald **Bohr**: Nearly periodic functions.—G. **Valiron**: The theorem of Picard-Borel.—A. **Guillet**: The synchronisation of circular movements.—M. **Huguenard**: A method for the absolute measurement of the velocity of a current of air. This method utilises a novel principle. During the passage of an electric spark in air, in addition to the sound-wave, a little cloud of warm air is formed which can be rendered visible by means of a second spark placed on the axis of the first. If the air is moving, this cloud is carried along at the velocity of the air current and its position determined by eye for low velocities or photographically for high velocities. A diagram and description of the apparatus is given: it is not necessary to know the temperature or pressure of the gas nor the velocity of sound, and very high velocities can be readily measured by this method.—Marius **Pascal**: Observations on the note by M. P. Noaillon on "Superficial circulation."—P. **Idrac**: The structure of sea winds and their utilisation for hovering flight. A summary of the results of experiments on the movements of air currents over the sea, carried out during the autumn at the lighthouse of Jument d'Ouessant.—Alex. **Véronnet**: The evolution of the trajectory of a star in a resistant medium.

—W. W. **Heinrich**: The analytical prolongations of the limited problem.—Ladislas **Gorczinski**: The diminution of intensity in the red portion of the solar radiation, observed in Europe and at the equator. The measurements were made with bi-metallic actinometers (Michelson system) furnished with coloured glasses. Between the equator and latitude 52° N. there is a progressive increase in the intensity of the red portion of the solar radiation as the distance from the equator increases.—P. **Lambert**, G. **Déjardin**, and D. **Chalonge**: An attempt to prove the existence, at high altitude, of a solar radiation in the extreme ultra-violet. Photographs of the solar spectrum were made with a specially designed spectrograph at the Vallot Observatory at the summit of Mt. Blanc, the experiments being specially directed to detect ultra-violet light between the wave lengths 1900 Å. and 2150 Å. The results were negative, no impression being shown by the plate after 40 minutes' exposure. It is suggested that oxygen may possess absorption bands in this region, and this point is to be the subject of further experiments.—F. **Wolfers**: The diffusion of the X-rays and Bragg's law. The work of Stenström, Siegbahn, Hjalmar, and Duane and Patterson has shown that Bragg's law, $\kappa\lambda = 2a \sin \alpha$ is not rigorously true, the angles measured in the higher orders being a little too small. The author shows that it is possible to explain these deviations in a manner compatible with the quanta theory, assuming only that diffusion in a crystal of any substance is of the same nature. The deviations calculated from the theory thus developed are compared with the measurements of Hjalmar.—E. **Darmois** and J. **Périn**: Cryoscopy in $Na_2SO_4 . 10H_2O$. The molecular magnitude of the malates, molybdates, and molybdomalates. Cryscopic measurements show that these complex molybdic acids are all derived from two molecules of malic acid.—Paul **Pascal**: The constitution and evolution of the metallic oxides and hydroxides. Magnetic analysis serves to distinguish water of hydration from water of constitution. Applications of the method to the cases of cadmium hydroxide, magnesium hydroxide, and zinc hydroxide are given in detail.—P. **Brenans** and C. **Prost**: The *p*-iodoxybenzoic acids. Description of the preparation of the iodo- derivatives of para-oxybenzoic acid, $C_6H_3I(OH)(CO.OH)$ (3:4:1) and $C_6H_2I_2$ (OH)(CO.OH) (3,5 : 4 : 1).—E. **Kohn-Abrest** and J. **Ricardoni**: A new method of estimating hydrocyanic acid in cyanogenetic plants. The hydrocyanic acid is removed from the cold solution by means of a current of air passed for a period of eight hours.—A. **Baldit**: The trajectories of storms and their splitting up into two.—Marc **Bridel** and Pierre **Delauney**: The properties of loroglossin and its products of hydrolysis: glucose and loroglossigenine. Loroglossin, under the action of emulsin, gives glucose and a new substance, loroglossigenine. The latter has been obtained in the crystalline form, but in a quantity too small for complete analysis.—C. **Fromageot**: The influence of the concentration of salts in sea water on the assimilation of green Algae. The intensity of the photosynthesis varies appreciably with the concentration of the medium. There is an optimum saline concentration for the photosynthesis, and this concentration is precisely that of sea water.—F. W. T. **Hunger**: The nature of the cocoanut pearl and its formation.—Georges **Claude**: The transformation of ammonia into fertiliser.—J. **Athanasiu**: The nervous motive energy of the heart and the nature of the contraction of the myocardium.—Charles **Benoit** and André **Helbronner**: The antagonism of radiations. Physiological and therapeutic consequences. In the field of physiology, the effect of irradiation by ultra-violet light is increased both in intensity and rapidity by a preliminary infra-red irradiation. On the other hand, the effects tend to be neutralised by a subsequent infra-red irradiation.—Jacques **Pellegrin**: A new apodal fish from the Bay of California, and its biology.—J. **Legendre**: The zoophilia of certain mosquitoes and its application to prophylaxy. In some regions *Culex pipiens* and *Anopheles maculipennis* both attack man, but it has been noted that at a coast station in Brittany, where these species are present together, neither attacks man. It is suggested that one of these insects might be used to suppress the other, and an experiment in this direction has been started.—A. **Vandel**: The existence and conditions of parthenogenesis in a terrestrial Isopod: *Trichoniscus* (*Spiloniscus*) *provisorius*.—A. **Desgrez**, H. **Bierry**, and F. **Rathery**: The utility of vitamin B and of levulose in the cure by insulin. The transitory effect of insulin in diabetes may be increased and prolonged by a suitable food regime. The addition of either vitamin B or levulose, or a mixture of both, allows the insulin injections to be made at longer intervals and thus increases the useful effect of a given amount of this substance.—Mme. J. Samuel **Lattès**: The corpuscular nature of the radiation responsible for the phenomenon of necrosis (produced by the X-rays) and on the best thickness of the filters.—M. **Sluys**: The creation of multiple foci of the secondary β-radiation in the middle of the tissues for a therapeutic purpose.—Charles **Richet** and Jean **Célice**: Local sera therapy in acute infantile gastro-enteritis.

SYDNEY.

Linnean Society of New South Wales, August 29.—Mr. A. F. Basset Hull, president, in the chair.—Vera **Irwin-Smith**: Studies in life-histories of Australian Diptera Brachycera. ii. Asilidæ. No. 1. Catalogue of the species of Asilidæ of which the earlier stages have been recorded. Asilidæ. No. 2. Notes on the egg-laying, eggs and young larvæ of *Neoaratus hercules* Wied. Larvæ were hatched from eggs laid by a female in captivity. The eggs were 1·1-1·2 mm. long and 0·40-0·43 mm. broad, and the newly-hatched larvæ were 2·2-2·6 mm. long. The eggs are distinguished by a characteristic pattern in dark pigment on the inner layer of the shell.—J. **McLuckie**: Studies in symbiosis. v. A contribution to the physiology of *Gastrodia sesamoides* (R.Br.). An account of the mycorhiza and the bacteria associated with the rhizomes of the species, and their relation to the higher plant. The nutritive phase of the association of fungal hyphæ, bacteria and Orchid is also discussed.—J. M. **Petrie**: Studies in plant pigments. i. The yellow colouring-matter of the Acacias. Four different species of Acacia (*A. discolor*, *A. linifolia*, *A. decurrens* and *A. longifolia*) have been examined to ascertain the nature of the colouring matter of their yellow inflorescences. The water soluble yellow pigment was a glucoside of kæmpferol, which exists in the flowers as a rhamnose glucoside; no free flavonol was found. The Acacia tannins were composed of phloroglucinol, protocatechuic and gallic acids and deposited on hydrolysis large amounts of red phlobaphene anhydrides. The carotin and xanthophyll as plastid pigments were present in amounts from 0·14 to 0·3 per cent., and the flavonol about 0·06 per cent. of the fresh flowers.—E. W. **Ferguson**: Revision of the Amycterides (Coleoptera). Pt. viii. The Euomides. There is no single character separating this group from the remainder of the subfamily. All the described species are reviewed and in many cases redescribed from the types. The descriptions of ten new species and two new varieties are included.

Official Publications Received.

Diary of Societies.

SATURDAY, NOVEMBER 17.

BRITISH MYCOLOGICAL SOCIETY (in Botany Department, University College), at 11.—Miss R. Bracher: Observations on Rhytisma.—J. J. Clarke: Notes on some Mycological Chromidia.—W. J. Dowson: A Mould attacking Sweet Peas.—Dr. A. S. Horne and G. H. Jones: Further Contributions to the Study of Eidamia.—R. Paulson: Observations on Tree Mycorrhiza.—A. A. Pearson: A Foray in Paris.

BRITISH PSYCHOLOGICAL SOCIETY (General Meeting conjointly with the Æsthetic Section) (at King's College), at 3.15.—R. Fry: What Artists want from Psycho-Analysis.

MONDAY, NOVEMBER 19.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—A. B. Eason and others: Discussion on Power in Telephone Exchanges.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—Prof. T. P. Nunn: The Philosophy of Signor Gentile.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section, London), at 7.—Special Exhibition of Industrial Kinematograph Films.

ROYAL INSTITUTE OF BRITISH ARCHITECTS (at 1 Wimpole Street), at 8.—G. T. Forrest: The Rebuilding of Ypres.

ROYAL SOCIETY OF ARTS, at 8.—S. H. Davies: The Cultivation of Cocoa in British Tropical Colonies.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Count Byron de Prorok: Results of Recent Research at Carthage.

TUESDAY, NOVEMBER 20.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—E. Gosse: Personal Relations between Medicine and Literature (David Lloyd Roberts Lecture).

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—The Secretary: (1) Report on the Additions to the Society's Menagerie during the month of October 1923; (2) Exhibition of a Collection of Autographs recently presented the Society by Mr. Hugh S. Gladstone.—W. E. Le Gros Clark: Notes on the Living Tarsier.—Dr. Francis, Baron Nopsca: Reversible and Irreversible Evolution; a Study based on Reptiles.—Dr. J. R. Garrood: Two Skeletons of the Cetacean *Pseudorca crassidens* from Thorney Fen, Cambridgeshire.—Dr. C. Crossland: Polychæta of Tropical East Africa, the Red Sea, and Cape Verde Islands; and of the Maldive Archipelago.—Miss Joan B. Procter: (1) New and Rare Reptiles from South America; (2) New and Rare Reptiles and Batrachians from the Australian Region.

INSTITUTION OF CIVIL ENGINEERS, at 6.—R. F. Grantham: The Effect of Groyning on Some Parts of the English Coast.—E. W. Hollingworth: The Tides from an Engineer's Standpoint.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—H. Campbell: The Gas Turbine.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Meeting organised by the Scientific and Technical Group.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—L. H. Dudley Buxton: The Inhabitants of Inner Mongolia.

CIRCLE OF SCIENTIFIC, TECHNICAL, AND TRADE JOURNALISTS, at 8.15.—Sir Richard Gregory: Progress in Science and Invention.

WEDNESDAY, NOVEMBER 21.

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting.

ROYAL METEOROLOGICAL SOCIETY, at 5.—L. F. Richardson: Attempts to measure Air Temperature by shooting Spheres upward.—Col. H. G. Lyons: Exhibit of a Replica of an Early Korean Raingauge.—F. J. W. Whipple: Exhibit of a Limit-gauge for Rainfall.—S. N. Sen: The Distribution of Air Density over the Globe.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. L. J. Wills: The Development of the Severn Valley in the Neighbourhood of Ironbridge and Bridgnorth.

INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.—H. H. Mardon: Address.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—Dr. E. V. Appleton and F. S. Thompson: Periodic Trigger Reception.—R. C. Clinker: A Dynamic Model of a Valve and Oscillating Circuit.

INSTITUTION OF PRODUCTION ENGINEERS (at Engineers' Club), at 7.30.—A. W. Swan: The Use of Charts in Engineering.

ROYAL MICROSCOPICAL SOCIETY, at 7.45.—F. R. Brambell: Sex-Reversal and Intersexuality.—Prof. J. Bronte Gatenby: Further Evidence on the Transition of Peritoneal Cells into Germ-Cells in Amphibia.—Dr. M. Johnston: The Preparation of Eel Scales for Microscopic Examination.—F. I. G. Rawlins: The Microscope in Physics.—Dr. H. M. Woodcock: Exhibition of Bacteriomorphic Granules (or Granules Simulating Bacteria) resulting from Cell-lysis or Digestion.

ROYAL SOCIETY OF ARTS, at 8.—A. Knowles: Forgeries of Ancient Stained Glass.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

THURSDAY, NOVEMBER 22.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (at 11 Chandos Street, W.1), at 2.45.—Prof. D. C. Winckler: The Psychiatrical and Neurological Teaching at the Dutch Universities, especially at the University of Utrecht.

ROYAL SOCIETY, at 4.—Special General Meeting to consider the Annual Report of Council.—At 4.30.—F. Simeon: The Carbon Arc Spectrum in the Extreme Ultra-Violet, II.—H. J. Gough and Dr. D. Hanson: The Behaviour of Metals subjected to Repeated Stresses.—W. Suckamith and L. F. Bates: A Null Method of Measuring the Gyro-Magnetic Ratio.—J. H. Shaxby: Studies in Brownian Movement, II. The Determination of Avogadro's Number from Observations on Bacteria (Cocci).—*To be read in title only*:—Dr. H. Hartridge and F. J. W. Roughton: The Kinetics of Hæmoglobin, II.—A. F. A. Young: The Thermionic and Photo-Electric Properties of the Electro-Positive Metals.—O. F. T. Roberts: The Theoretical Scattering of Smoke in a Turbulent Atmosphere.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. J. J. Findlay: Rhythm, Labour, and Child Development.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—A. Bachellery: The Electrification of the Midi Railway (Joint Meeting with the British Section of the Société des Ingénieurs Civils de France).

SOCIETY OF DYERS AND COLOURISTS (London Section) (at Dyers' Hall, Dowgate Hill, E.C.3), at 7.—A. D. Lang: Macbeth Artificial Daylight, and the Fade-ometer.

FRIDAY, NOVEMBER 23.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—F. Martin Duncan: Lantern Lecture.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—British Locomotive Practice and Performance.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—W. A. Tookey: Technical Arbitrations.

PUBLIC LECTURES.

SATURDAY, NOVEMBER 17.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—G. Morris: The Prehistoric Survey of Selborne.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—S. H. Warren: The Cave-Paintings of Stone Age Man in Europe.

MONDAY, NOVEMBER 19.

KING'S COLLEGE, LONDON, at 5.30.—Prof. W. T. Gordon: Gem Minerals and their Uses in Art and Industry (Swiney Lectures). (Succeeding Lectures on November 21, 23, 26, 28, 30, December 3, 5, 7, 10, 12, and 14.)

TUESDAY, NOVEMBER 20.

UNIVERSITY COLLEGE, at 5.30.—Engr.-Capt. E. C. Smith: Epochs in the History of Marine Engineering.

WEDNESDAY, NOVEMBER 21.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. C. W. Saleeby: Sunlight and Disease.

UNIVERSITY COLLEGE, at 5.30.—A. Jenkinson: Handwriting and Early Printing.

THURSDAY, NOVEMBER 22.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, at 5.15.—Dr. J. W. Heslop Harrison: Problems of Variation. (Succeeding Lecture on November 23.)

LONDON SCHOOL OF ECONOMICS, at 5.30.—F. S. Marvin: Great Britain and Europe (League of Nations Union Lecture).

FRIDAY, NOVEMBER 23.

KING'S COLLEGE, LONDON, at 5.30.—C. E. M. Joad: The Philosophical Background of Music and Poetry: (1) The Function of Art.

ROYAL SOCIETY OF ARTS, at 8.—Major H. Barnes: Hygiene and Architecture: Remedial Hygiene—Health and the Hospital (Chadwick Lecture).

SATURDAY, NOVEMBER 24.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss E. Goodyear: The Romance of the Highways.

The Development of Cotton-growing in the British Empire.[1]

IN the years before the War, the exportable surplus of cotton from the United States was well over 4000 millions of pounds, or 8 millions of bales of 500 lb. each. At the present time it is only about $4\frac{1}{2}$ millions of bales (in very approximate figures), and there does not seem much possibility of any increase. This is due to various causes, chief among which may be mentioned (1) the ravages of the cotton-boll weevil, which has now, after thirty years have passed since its first invasion, spread over the whole cotton-growing region of the Southern States; and (2) the fact that the United States are every year consuming more and more cotton for the supply of their own mills. The demand for cotton goods in America seems insatiable, and is one of the principal factors in bringing about the present unfortunate situation in the British cotton industry.

American cotton, the fibre (or staple) of which is from an inch to an inch and one-eighth in length, provides the enormous bulk of the supply for Lancashire, the mills of which are constructed to deal with cotton of this length, and cannot at a moment's notice be altered to suit any other kind. Nor is there any other kind available in sufficient quantity, to say nothing of the fact that the demand is for goods of the present quality, which could not be equalled by spinning a cotton of shorter staple. The confusion of the exchanges, the diminished purchasing power of continental nations, and the smaller demand from India, have all contributed to lower the demand for Lancashire fabrics, but can scarcely go much further in that direction; and the consumption in America is increasing. Any rise in the Old World demand would cause the shortage to be felt even more acutely than it is, and even at present it is a very serious matter, which is reflected in the very high price at which cotton stands. American middling (the standard of the market) is now (Nov. 8) at 19·28*d.* per lb., against an average of 6·46*d.* in 1914.

In these circumstances the increased production of cotton of staple approximately equal to middling American, and elsewhere than in the United States, has become an urgent necessity, if the greatest manufacturing industry of Great Britain—upon which it is estimated that ten millions of people are dependent—is not to fall upon very evil days, which may mean widespread unemployment and distress. Among the most obvious countries in which to set to work to remedy the matter are those comprised within the British Empire. Dependence upon them for the supply of raw cotton would also bring other advantages in its

[1] Empire Cotton Growing Corporation. Report of the Administrative Council. Presented at the second annual general meeting on October 10.

train—it would give a fillip to colonial development, it would reduce the payments to be made to the United States, and would save paying in depreciated currency. Already for twenty years the British Cotton Growing Association has been devoting much money and effort to this object, and with considerable success—to such an extent, indeed, that the first and most difficult corner has been turned in several of the colonies, where cotton is now established among the possible crops that may be grown for profit. For some time, however, it has been felt that still greater and more widely organised effort is needed, and with this object in view there has been formed the Empire Cotton Growing Corporation, the sources of the funds of which are a capital grant from Government and a compulsory levy of *6d.* upon every 500 lb. of cotton purchased by spinners. The second annual meeting has just been held, under the presidency of Lord Derby.

Our thoughts turn naturally and first of all to India, as the second largest producer of cotton in the world. At present, however, that country counts for little so far as Lancashire is concerned, though producing every year some 4½-5 million bales. Only 243,000 were sent to Great Britain in the year ending July 31 last, and only 107,000 were consumed. The bulk of the cotton, which is mostly of short staple and poor quality, is used in Indian mills, or exported to Japan, and to a less degree to the continent of Europe. The locally made cloth, though somewhat coarse in texture, is of excellent wearing quality, and satisfies at a moderate cost a great part of the local demand.

As there seems to be small chance of growing in India within a short time large quantities of the longer-stapled cotton which Lancashire needs, attention must be directed to Africa and Australia. The Asiatic portions of the Empire outside India are in general too wet for the successful cultivation of cotton upon the large scale, whilst the West Indies have already devoted much of their small available area to the production of Sea Island cotton, which has the longest and finest fibre of all. The market for this cotton is but a small one, and the few thousand bales which are exported from the West Indies supply practically all of its requirements.

By far the largest producer in Africa, and one of the most important in the world, on account of the fine quality and long staple of its cotton, is Egypt. Recent political changes, however, have excluded this country from the Empire, and it remains to be seen whether the effect of these may not be to make even worse the present difficult situation in cotton, by involving a falling-off in production, or a deterioration of the quality or length of staple.

In the rest of Africa the cultivation of cotton for export is still comparatively new, and that it exists at all is due to the work of the British Cotton Growing Association referred to above. Cotton-growing is now becoming of serious importance in the Sudan, in Uganda, and in Nigeria, while South Africa, Tanganyika, and other parts are making a good start. In all of them the export is increasing, and in Uganda it now reaches the respectable figure of about 90,000 bales annually (Lancashire now uses about 3 million bales of American cotton). The important fact is that the corner has been turned, and many people know that cotton can be cultivated to a profit in these regions, so that others will probably follow their example, and the export will increase. After having cultivated cotton for some years, people will be less likely to abandon it in the event of an unpropitious year, and the cultivation will be much more likely to be permanent.

While in tropical Africa the crop is mainly in the hands of the natives of the country, there appears to be a good prospect that portions of South Africa may offer good prospects and suitable conditions for cultivation by people of European descent.

Finally, we must consider Australia, where the cultivation of cotton is carried on by white men. Queensland and New South Wales are proving to be excellently well suited to the crop, and the principal thing that remains to be seen is whether the policy of a "white Australia" will allow of enough labour for important extension. If this extension can take place, Australia should become a factor of serious importance upon the cotton markets.

The import into Lancashire of Empire-grown cotton is as yet but small compared to the enormous quantities arriving from the American continent, north and south, but it is by no means unimportant, and there is every reason to hope that at no very distant period, under the fostering care of the Empire Cotton Growing Corporation, it may reach a million bales, or about a quarter of the consumption.

The work of the Corporation is at present in its initial stages. A separate committee is at work in India upon somewhat similar lines, aided by a cess of 4 annas on every bale of cotton used or exported. Specialists have been appointed to report on prospects and conditions in South Africa and elsewhere, and some of the African colonies are being helped by grants made to their agricultural departments for the express purpose of work upon cotton under the supervision of specialists appointed by the Corporation. Research is under way in St. Vincent, grants-in-aid are being made to institutions conducting research in Great Britain, and the question of establishing a research station in some cotton-growing country is under consideration. A number of studentships have been given, and the

men are being trained at the Imperial College of Tropical Agriculture, Trinidad, at Cambridge, and elsewhere, while some of those who have finished their training are being employed in the African and other colonies in supervising work with cotton under the charge of the specialists. A large illustrative exhibit is being prepared for the British Empire Exhibition at Wembley next year, a journal is being started under the editorship of Dr. J. C. Willis, F.R.S., and in many other ways the Corporation is settling to work at the gigantic problem before it.

It is clear that the activities of the Corporation will be likely to result in a considerable demand for men of the right kind, and at present there is difficulty in finding these. Highly trained agriculturists with knowledge of cotton-growing are difficult to discover, nor does the supply of young men who have taken a degree in pure science and followed this with some agricultural training meet the demand which at present exists in this new branch of scientific tropical agriculture.

The Forests of India.

The Forests of India. By Prof. E. P. Stebbing. In 3 vols. Vol. 1. Pp. xv + 548 + 27 plates. Vol. 2: *The Development of the Indian Forest Service.* Pp. xii + 633 + 36 plates. (London: John Lane, The Bodley Head, Ltd., 1922–1923.) 42*s.* net each.

PROF. STEBBING'S work deals with the history of forest conservancy in India from the time of the recent Post-Tertiary period to the present time. In volume i. he gives the history from the earliest date to the year 1864; in volume ii. from 1864 to 1900; the period 1900 to the present time is reserved for volume iii., not yet published. The matter assigned to volume i. is further divided into four sub-periods, the last of which comprises the years 1857–1863. Volume ii. is divided into two sub-periods, the first of which comprises the years 1864–1870. The author then, in a way, throws these two sub-periods together again and says that the fourteen years, 1857–1870, witnessed the true foundation of forest conservancy in the different provinces of the Indian Empire.

In the early part of volume i. the general features of India are indicated; its geography, geological features, climate, the distribution and the general character of the forests at the time of the arrival of the English in India. Fire, shifting cultivation, and careless utilisation had considerably reduced the area of the forests and changed their composition, a process which went on, practically unchecked, until the middle of the nineteenth century. The East India Company periodically directed attention to the mischief and urged the adoption of measures to stop it, but the Government of the country did not take action until the Bombay Dockyards ran short of timber for naval construction. A timber agency was set up early in the nineteenth century, but abolished again in 1823, in consequence of its arbitrary proceedings. For some time after this, any small progress was due more to the exertions of active individuals in the services than to the Government as a whole. Among these Mr. Conolly, the Collector of Malabar, stands out. He started the well-known Nilambur teak plantation in 1843. This was so successful that it proved the possibility of making forest conservancy in India financially profitable. Other examples are the activity of Dr. Gibson in Bombay, Dr. Cleghorn in Mysore and Madras, and Dr. Wallich, Capt. Tremenheere, and Mr. Colvin in Burma. These officers and many others did, no doubt, a great deal of good, but their efforts were disjointed; however, they created a feeling that action on a definite plan was wanted.

In 1855 Lord Dalhousie took up the matter. His first step was to appoint Dr. Brandis superintendent of the Pegu teak forests. The latter joined in Burma in 1856, and, supported by Major Phayre, the Commissioner of Pegu, during the following six years he saved the Lower Burma teak forest from the threatening destruction. Soon after the effect of the Mutiny had somewhat subsided, the Government of India began to occupy itself with the question of more effective forest conservancy generally. Dr. Cleghorn was called up from Madras in 1861 to advise about forest conservancy in Upper India, and a year later Dr. Brandis (it is said on Dr. Cleghorn's suggestion) was brought up from Burma to join in the work. In 1864 the Government, with the approval of the Secretary of State for India, established a regular Forest Department with Dr. Brandis as first Inspector-General of Forests.

Dr. Brandis was a man of science, of great knowledge and endowed with a remarkable working power. He had recognised in Burma that lasting benefit could not be achieved without placing the forest business on a legal basis, and he succeeded in having a special Forest Act passed in 1865. That Act had, however, a great defect: it did not provide a legal inquiry and regulation of rights of third persons in the areas proposed for permanent State forests. Hence, in 1868, Brandis proposed a revised Act, and this proposal led to a protracted discussion which did not end until 1878, when the Indian Forest Act passed the Legislative Council. It is still in force with some minor additions, but special Acts were passed for Burma and Madras based on the same principles as the Indian Act but providing for some provincial differences. All these Acts give power to inquire into, regulate, and, if necessary, commute the rights of third persons in areas declared or proposed as Reserved State Forests; to

establish village forests to be managed for the benefit of local communities; to protect the forests generally as well as their produce; to organise the administration and working of the forests, and allied matters.

Brandis, on taking charge of the Department, found the existing staff sadly deficient. There were some excellent administrators in it, mostly military officers, including medical men, but there was little knowledge of systematic management with the object of securing a sustained yield in the future. His plan, from the outset, was to obtain a sufficient number of scientifically trained officers, to start the treatment of the forests on the right lines, and to utilise them for the training of Indians to fill the posts of rangers and foresters, promotion to the superior grade being open to those who were fit for it. There being, at that time, no opportunity in India or in Britain to acquire a high standard of scientific forestry, Brandis proposed to send young Englishmen for the necessary instruction to the Continent, Germany and France, where systematic forest management had been practised for more than a century. In the meantime the service in the several provinces of India was organised as well as possible. The formation of Reserved State Forests was commenced, the methods of exploitation improved, the general protection of the forests effected, and especially fire protection commenced, the latter being inaugurated successfully by Capt. Pearson in the Central Provinces. Shifting cultivation in the valuable parts of the forests was restricted or at any rate regulated, taungya teak cultivation in connexion with shifting cultivation introduced in Burma, whence it has spread to other parts of India and produced highly important results.

From the very beginning Brandis drew up preliminary working plans for the forests which he visited, a practice which he continued up to the time of his leaving India. Other officers followed his example, but, as the administration had to a considerable extent been provincialised, there was no security for the plans being executed. When Dr. Schlich took over the Inspector-Generalship from Dr. Brandis in 1881, he recognised that, to secure a continuous yield from the forests in the future, steps must be taken to push on the preparation of working plans based on the principle of a sustained yield, and especially to secure the execution of the plans when once sanctioned by Government. He obtained the sanction of the Government of India and of the Secretary of State for India for the establishment of a Working Plans Branch under the supervision of the Inspector-General, assisted by an Assistant Inspector-General. The plans were prepared under the direction of the local governments, but the Inspector-General had to be consulted as to the lines on which they were to be drawn up, and, when once approved by the local government, he was kept informed of the progress of execution, so that he could direct the attention of the local government to any deviation from the sanctioned provisions. It was foreseen at the time that, as the operations of the Department developed, the control would have to be handed over to the local authorities, and this has now actually been done. The establishment of this branch was, as Prof. Stebbing states in volume ii., considered "an epoch-making move forward." As a result nearly all important forests are now worked under the provisions of well-prepared plans; moreover, the yield capacity of the forests became known and can safely be worked up to, while a great store of valuable information bearing on the silviculture and general management of the forests was put on record. It is not too much to say that the establishment of the Working Plan Branch was a forerunner of the Forest Research Institute at Dehra Dun, which, however, did not come until twenty-two years afterwards.

Prof. Stebbing deals in detail with the development of the education of the staff, both superior and subordinate. The recruits for the former continued to be educated on the Continent until 1886, but in 1885 the first School of Forestry in Britain was opened at Cooper's Hill. The organisation of this was entrusted to Sir William Schlich. It remained at Cooper's Hill until 1905, when it was transferred to the University of Oxford. As soon as a sufficient number of duly qualified teachers of forestry had been secured, the establishment of an Indian School of Forestry at Dehra Dun was effected, in 1878, for the training of the ranger class of officers. It was gradually improved, so that by 1900 it had been brought up to a standard which made it possible to undertake the instruction of the recruits of the provincial part of the controlling staff. Indeed, it is likely that soon the whole of the superior staff will be educated at Dehra Dun.

Prof. Stebbing says in the preface to volume ii. that the fourteen years, 1857 to 1870, witnessed the true foundation of forest conservancy in the different provinces of the Indian Empire, and that the work which was undertaken during the period 1871–1900 was the natural corollary and outcome of the lines laid down between 1857 and 1870. This is, in our opinion, an exaggerated view, because, as has been indicated above, several of the most important measures which secured the success of the whole undertaking were conceived and introduced during the period 1870–1900. Not only was all the spade-work done during the latter period, but also rational forest conservancy became an established fact. Not far short of 100,000 square miles had definitely become permanent State forests; the greater part of these were worked according to the

provisions of well-prepared working plans; more than half the area was protected against the annually recurring forest fires; most of these areas had been surveyed and mapped; the education of the staff had reached a high standard; and, last but not least, a remarkable amount of research had been accomplished during the period, as evidenced by such works as Brandis's "Forest Flora of North-West and Central India," a book of such excellence that the author was forthwith elected a fellow of the Royal Society; Gamble's "Manual of Indian Timbers" and his great work on Indian "Bamboos"; and Baden Powell's "Forest Law." Nor should it be forgotten that the greater part of the material with which Brandis dealt in that monumental work entitled "Indian Trees" was collected during the second half of last century, although the book was not published until 1906. It would lead too far to mention works on forestry proper. The *Indian Forester* was started by Sir William Schlich in 1875. Prof. Stebbing calls it a mine of information from a perusal of which a great deal is to be learned. A great quantity of observations on the silviculture of Indian trees is incorporated in numerous reports, and it has only lately been collected and made available to foresters generally. Unfortunately, the establishment of the Forest Research Institute at Dehra Dun was too long delayed, but what part of the Empire has not sinned in the same manner?

Twenty chapters of volume i. and ten chapters of volume ii. are devoted to a description of the progress in forest conservancy in the several provinces of India. The last chapter of volume ii. contains an appreciation of three Inspectors-General of Forestry. Prof. Stebbing gives the text of resolutions by the Government of India acknowledging the services of Sir Dietrich Brandis and of Mr. Ribbentrop, and remarks that no such resolution was passed acknowledging the services of Sir William Schlich. The latter statement is not correct, as a resolution acknowledging the valuable and distinguished services of the last-mentioned was passed by the Governor-General in Council on February 7 and published in the *Gazette of India* of February 9, 1889.

Apart from some passages which might be questioned by past or present members of the Indian Forest Service, Prof. Stebbing has produced a very full account of the development of Indian forest conservancy up to the year 1900. It is based on the study of a vast number of works and writings, among which Ribbentrop's "Forestry in British India" takes a prominent place. A rainfall map is attached to volume i., and a general map of India to volume ii. Sixty-three artistic illustrations are inserted, and they serve as pleasing resting-places during the perusal of the book.

Cambridge Biographies.

Alumni Cantabrigienses: a Biographical List of all known Students, Graduates, and Holders of Office at the University of Cambridge, from the Earliest Times to 1900. Compiled by Dr. John Venn and J. A. Venn. Part 1: From the Earliest Times to 1751. Vol. 2: Dabbs—Juxton. Pp. v+492. (Cambridge: at the University Press, 1922.) 7*l.* 10*s.* net.

THE second volume of this monument of industry and antiquarian research carries the list of members of Cambridge University prior to 1751 down to the name of Juxton. The first four volumes, covering the whole of the early period, are to be published by the end of next year, and the editors now ask for additions and corrections to the data already published.

In the present volume, among men of science of repute we note the names of De Moivre, a Protestant refugee from France, and Sir Kenelm Digby, one of the original members of the Royal Society, who was at one time banished to France; Thomas Gale, regius professor of Greek and first secretary to the Royal Society; J. Flamsteed, first Astronomer Royal, and Jeremiah Horrox, who predicted and observed the transit of Venus in 1639; Gilbert, the physicist, and William Harvey and Glisson among many distinguished members of the medical profession. Of those who combined eminence in two distinct branches of science may be mentioned Dacres, who was professor of geometry and censor of the Royal College of Physicians. Of those known more widely in a different sphere we note John Dryden, who was discommuned for contumacy to the Vice-Master of Trinity; the Duke of Northumberland, Chancellor to the University in 1551, who was executed on Tower Hill; N. Eaton, first master at the school in Cambridge, Mass., which afterwards became Harvard College—and John Harvard himself. Orlando Gibbons, Thomas Gray, George Herbert, Robert Herrick, and Ben Jonson bear witness to Cambridge's continued love of the muses; the name of Judge Jeffreys strikes another note, as also do the names of Erasmus, Thomas Gresham, founder of the Royal Exchange, and Thomas Hobbes.

Amongst distinguished Cambridge families we find the Darwins and the Howards. The latter in their history bear witness to the religious disputes which have in the past left their stamp on Cambridge as on England. Martyrs on both sides were educated there. The position of Cambridge in the Civil War is suggested by the names of Fairfax, Fleetwood, Hesilrig, and Hollis, though the Earl of Montrose represents the other side. Among the points of human rather than of historical interest we may note the sentence of transportation on Henry Justice for stealing books from the University Library, and the history of Adam Elliot, a slave to

Moorish pirates. Francis Dawes, who hanged himself with the chapel bell-rope, must have had a grim sense of humour. Lastly, the modern touch giving the sense of continuity in the history of Cambridge is supplied by William Hawteyne, who went out as an army chaplain in Flanders and Germany.

The *Quest* Expedition and its Lessons.

Shackleton's Last Voyage: the Story of the "Quest." By Comdr. Frank Wild. From the Official Journal and Private Diary kept by Dr. A. H. Macklin. Pp. xvi + 372 + 100 plates. (London, New York, Toronto and Melbourne: Cassell and Co. Ltd., 1923.) 30*s.* net.

CLOSE upon the heels of the excellent "Life of Sir Ernest Shackleton," by Dr. H. R. Mill, comes the story of his last voyage. It is told by his old comrade in adventure, who took part in all the expeditions with which Shackleton was connected, and whose experience of Antarctic life was even greater than Shackleton's. Commander Wild is assisted in his literary labour by a member of the expedition who seems to have been invaluable at every turn, Dr. A. H. Macklin.

The tale is told in a plain, straightforward manner which reflects the character of the writers, who ask neither for eulogy nor for sympathy, although both will be readily forthcoming. Of the success they hoped for there was but little, of the bitterness of thwarted plans there was much, but there is small mention of either. The events of the voyage are duly chronicled, and comment is usually reduced to the minimum. The main features of these events are already well known through the medium of the daily press, but the book adds to them so much in the way of personal detail, and the pros and cons of the decisions which were made, that we recognise at once the inadequacy of a press narrative.

The expedition was unfortunate almost throughout, and the story resolves itself into a tale of misfortunes endured or overcome, many but not all of which were unavoidable. The crowning misfortune, the loss of its leader before the expedition had even reached its cruising ground, would have wrecked the future of most expeditions, and it is this which absorbs one's interest and overshadows the other incidents to a great extent. Every reader, and especially those with Antarctic experience, will admire the spirit of Wild's decision to "carry on" after the death of the leader; indeed, in the circumstances as given in this book, none would have blamed him had he turned back.

It is the duty of every leader of an expedition to write its narrative, the tale of the things done; but as he writes it we suspect that he writes a second one in his own mind, the tale of the things left undone and the things he did unwisely, and there can be no doubt that the one which does not reach the printer is the more valuable of the two. It is in no unfriendly spirit, and with the greatest admiration for all the actors in the story, that we propose to examine some of the causes of misfortune, causes which must be writ large in Commander Wild's own mind as things he would avoid next time. It is the business of those interested in polar exploration to extract the lessons of the past as well as to applaud its successes.

With so popular a leader, so varied a programme, and so small a ship, it was perhaps inevitable that the expedition should have become the prey of the sensation-monger reporter before it started. Such a fate should rank perhaps as a nuisance rather than as a misfortune, but it was scarcely fair either to the leader, harassed with the thousand details of preparation, or to the members, most of whom had their polar spurs yet to win, to find the press following every movement, publishing every plan, and "featuring" every detail down to the ship's cat.

Beside such a small matter, the enforced change of plans at a late date was a very real misfortune. The fundamental character of this change, for which but a few months was available, is perhaps not appreciated by the general reader, to whom the Arctic and the Antarctic are merely opposite poles of cold and unpleasantness. The change was really from a short North Atlantic voyage followed by sledging exploration in the Beaufort Sea—essentially a land expedition, in fact—to an oceanographical cruise in the stormiest seas of the world, essentially a ship expedition. We deplore the change for other reasons, for we believe that a leader with the qualities of Shackleton, and followed by the men he had selected, would have made great discoveries in the blank spaces of the Beaufort Sea. Indeed, only the most urgent circumstances could have prevailed on the leader to make such a change, circumstances not at all covered by the phrase, "as it was too late to catch the Arctic open season the northern expedition was cancelled."

Even so, we think that success would have been somehow achieved were it not that the element of hurry now came doubly into the preparations, an element which must have been responsible for the totally inadequate survey of the *Quest's* boilers and engines, the defects in which crippled the expedition from the moment it left England. It is sad to read, for example, that only after infinite delay and expense, enforcing vital changes in the plans—in fact, only after reaching South Georgia—was it found on consulting the ship's record that the boilers were thirty-one years old, and Commander Wild marks his surprise and chagrin by

printing the fact in italics. While these fundamentals were somehow overlooked, the ship was equipped with an array of special fittings such as no former polar ship could boast—enclosed bridge, clear-view screens, gyroscopic compasses, double set of wireless, etc.—all very helpful, no doubt, but one can imagine the remarks of the ship's officers when, though surrounded by these devices, they had to nurse a leaky boiler and a crankshaft out of the true.

The initial cost of the *Quest*, a small wooden vessel of 125 tons, was 11,000*l.*, and we imagine that before she returned at least as much again must have been spent upon her. Even allowing for the fact that she was bought when the shipping market was at its peak, it is clear that oceanographical or polar expeditions are ruinously expensive, nor can former expeditions present much more satisfactory balance-sheets.

The *Discovery* was designed and built in 1900 for Antarctic exploration, and cost more than 50,000*l.*; she was sold afterwards for a fraction of that sum. She is now being reconditioned at a cost comparable with her first cost, to continue, after twenty years, the work for which she was originally designed. During that period Scott, Shackleton, and Mawson, to mention only the chief leaders, have wanted her and had to put up either with inferior ships or have lost heavily over buying and selling. Meanwhile, the only ship ever built specially for the Antarctic has been sealing or dry-rotting in dock. Manifestly we are here touching upon what might almost be called a scandal, but it is one for which no one in particular is responsible, unless it be the companies who make large profits by selling and buying exploring ships. The real scandal is that polar exploration is so little organised, the efforts are so spasmodic and independent, that it was no one's business to keep the *Discovery* after her first voyage and charter or lend her when she was again required.

That, we believe, is the real lesson to be learnt from the story of the *Quest*; and it is a lesson, not for the Shackletons and Wilds of the future, but for us stay-at-homes who urge them on, who even subscribe towards their ventures, but take no steps to secure continuity from one expedition to the next.

The book is well illustrated, but is extraordinarily deficient in good maps. It is time that publishers, if not their authors, realised that adequate maps are essential to such books and improve their selling prospects. Perhaps the most valuable part of the book is the medical appendix written by Dr. Macklin, in which he gives the most up-to-date summary of medical conditions on a polar expedition, with advice drawn from his own experience on such subjects as scurvy, frost-bites, and sledging rations.

F. DEBENHAM.

Metallurgical Furnaces.

The Flow of Gases in Furnaces. By Prof. W.-E. Groume-Grjimailo. Translated from Russian into French by Leon Dlougatch and A. Rothstein. Translated from the French by A. D. Williams. With an Appendix upon the Design of Open-Hearth Furnaces. Pp. xxi+399. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923.) 27*s.* 6*d.* net.

THE construction of furnaces for metallurgical purposes has been guided in general by rule of thumb, practical experience having shown a particular furnace to work well, and a similar design being adopted in new plant, without any established principles to serve as a guide to the designer. In 1911 there appeared an important work in Russian, by Prof. Groume-Grjimailo, in which an attempt was made to place the subject on a scientific basis. Being translated into French in 1914, and introduced to the French public by Prof. Le Chatelier, this novel treatise attracted much attention, and it has now been made available, in an extended form, to the English-speaking world. It should be studied with care wherever furnaces are used. The loss of heat in most metallurgical furnaces is large, and economies in this direction are of great importance in the improvement of industry, especially in view of the great increase in the cost of fuel.

The guiding principle of the work is recognition of the fact that the densities of hot and cold gases differ so much that a mass of flame passing through a furnace may be treated as if it were a light fluid, floating on the heavier mass of gas at a lower temperature beneath it. It is then possible to apply the laws of hydromechanics to the case of furnaces. For purposes of study and demonstration, sectional models of the furnaces are made, enclosed between sheets of plate glass, water being introduced, and a light liquid, such as kerosene, coloured for distinctness, being then admitted through the gas ports. It is then easy to see how the light liquid, representing flame, distributes itself through the furnace. The difference between the efficiencies of updraught and downdraught kilns is at once made evident by this method, and the use of such models is becoming common. Many examples are given by the author of furnaces which were unsatisfactory in their working, but became efficient on being reconstructed in accordance with these principles. The consequences are worked out quantitatively, and formulæ are arrived at which may be used by the furnace designer.

It may be suggested, however, that the author scarcely takes sufficient account of radiation as a means of supplying heat to the objects in the furnace. The translator has added greatly to the value of the work

by supplying long appendices on the design of Siemens furnaces, hot-blast stoves, and boiler settings, in which the author's principles are applied to a large number of concrete cases, with an abundance of numerical data. Tables of thermal data and curves giving the heat capacity and calorific intensity of some of the most typical gaseous and liquid fuels complete a book which should exert a great influence. C. H. D.

Our Bookshelf.

Periodicals of Medicine and the Allied Sciences in British Libraries. By Prof. R. T. Leiper; with the collaboration of H. M. Williams and G. Z. L. Le Bas. Pp. vi+193. (London: British Medical Association, n.d.) 10*s.* 6*d.*

THE provision of Union Lists of Periodicals filed in our University centres is now recognised to be an indispensable aid to research. Such Lists should be authoritative. They should be issued at frequent intervals and on a uniform basis of compilation. Their type should be kept standing with the view of reducing the labours of their compilers and the cost of successive editions to their buyers. Something has already been accomplished in this direction; but the ground is not yet adequately covered.

Union Lists of Periodicals, however, representing specific branches of knowledge, stand upon a less secure footing. Dr. Leiper's "Periodicals of Medicine and the Allied Sciences in British Libraries" illustrates the difficulties which beset the path of the untrained compiler of these sectional lists in the absence of a printed National Union List covering the whole range of periodical literature. Judged by the "standards which guide professional librarians" (we are quoting from Dr. Leiper's preface), the work before us cannot be regarded as satisfactory, in more than one respect. Wales, for example, is not represented in the List; the Scottish libraries are not represented by the Advocates' Library in Edinburgh, or the London libraries by the Library of the Patent Office. These are serious omissions. We do not, however, propose to justify our criticism further, for to some extent the defects in the List are admitted in the preface. We prefer to meet Dr. Leiper on his own ground. The compiler and his collaborators have grappled manfully with a very difficult task, and have succeeded in producing a work which will be serviceable to students in the field of medical research, provided that they do not lean too heavily upon its bibliographical sufficiency and accuracy. Further, we trust that its publication will serve to promote a higher co-ordination of work among professional librarians—in respect of which, as Dr. Leiper suggests, there is still great room for improvement.

Nickel Ores. By W. G. Rumbold. (Imperial Institute: Monographs on Mineral Resources, with special reference to the British Empire.) Pp. ix+81. (London: John Murray, 1923.) 5*s.* net.

THIS little volume is written in the same way and upon the same lines as its predecessors in the series of Imperial Institute monographs on mineral resources; that is to say, it commences with a brief account of the mode of occurrence and the character of nickel ores, the metallurgy of nickel, and the uses to which this metal is put industrially, followed by a description of the occurrences of nickel ores within the British Empire, and finally of the foreign sources of supply of this metal. The task is in so far rendered an easy one because the author had at hand the well-known report of the Royal Ontario Nickel Commission published in 1917, in which the whole subject is most exhaustively dealt with. This great report is, however, too voluminous for the ordinary seeker after general information, and the present monograph fulfils a useful object in presenting the subject matter in a more convenient and more readily accessible form. It should be added that Mr. Rumbold has done his work very well. The section on the applications of nickel, although brief, is tolerably comprehensive, although more attention might perhaps have been given to nickel-plating, which is becoming of very great industrial importance. In other respects the author appears to have covered the ground very thoroughly;. he scarcely does full justice to the important part that Norway has played in nickel production in the past, and, to judge by the bibliography attached, does not seem to have consulted the tolerably extensive Norwegian literature on the subject. Upon the whole, it may fairly be said that the work carries out very well the intention of the series, namely, "to give a general account of the occurrences and commercial utilisation of the more important minerals."

Proceedings of the Aristotelian Society. New Series, Vol. 23: Containing the Papers read before the Society during the Forty-fourth Session, 1922–1923. Pp. ii+289. (London: Williams and Norgate, 1923.) 25*s.* net.

PHILOSOPHY takes account of the meaning of things. At the present time, it is partly occupied with new conceptions of the structure of the material universe, or matter, in terms of theoretical physics. Among the papers in the current issue of the Proceedings of the Aristotelian Society—mainly devoted to dialectical discussions of classical themes or the re-statement of old problems—attention may be directed to three. The Rev. Leslie Walker's "New Theory of Matter" —new, in the sense of its being pre-Aristotelian—is (he says) an attempt to deduce from relatively simple first principles the laws of co-existence and sequence which have been found experimentally to hold good between observed changes in the sphere both of quantity and quality. He finds that the essence of a thing lies in the fundamental structure or ratio—*forma substantialis*—which holds between the potentialities themselves.

Dr. E. S. Russell's "Psychobiology" is a monadistic conception—opposed to the mechanistic or vitalistic view—in which living things appear to show a persistent and enduring individuality of action unparalleled in the inorganic realm: structure and function, he maintains, must be treated as one and inseparable.

Prof. Sellars, in a thoughtful paper on the "Double-Knowledge Approach to the Mind-Body Problem," demands a deepening of our metaphysical categories: there exists, indeed, in Nature a level of causality,

of self-determination, which does not easily fit into the traditional interpretation of Nature.

Entomology: with Special Reference to its Ecological Aspects. By Prof. J. W. Folsom. Third revised edition. Pp. vii+502. (London: John Murray, 1923.) 21*s.* net.

PROF. FOLSOM'S well-known text-book gives a clear and concise account of the various aspects of entomology, and is written with the object of meeting the growing demand for a biological treatment of the subject. The present (third) edition includes a considerable amount of new letterpress, with the addition of an opportune chapter on insect ecology, and some 250 titles have been added to the bibliography. Considering the limited size of the book (500 pp.), the author has been remarkably successful in dealing with his subject in a comprehensive manner. An elementary treatment is, of course, only possible within this compass. Entomology, like other branches of science, has made such rapid strides during the last twelve years or so, that it is almost impossible to compress a really adequate work into less than 800 or 900 closely printed pages. There is a great need at the present time for a more advanced book, since works of an elementary nature are tolerably numerous. Among the latter, Prof. Folsom's book is undoubtably one of the best. The author's admirably terse and lucid style is of great value to the beginner, while the up-to-date bibliography, that is appended at the end, serves as a guide to the sources where fuller information is obtainable.

How to Build Amateur Valve Stations. By P. R. Coursey. Pp. 70. (London: The Wireless Press, Ltd.; New York: The Wireless Press, Inc., 1923.) 1*s.* 6*d.* net.

WE can recommend this book to all who want to take advantage of the latest developments of radio telephony. The author is equally at home on the scientific as well as on the practical side of the art, and experts attach weight to his views.

The very simple sets described can be trusted to work admirably on days when the electrical condition of the atmosphere is not very disturbed. A set for use in Great Britain should have a tuning range from 300 up to 2700 metres. This would include the Eiffel Tower time signals, which are usually made on a wave length of 2600 metres, the French "radiola" concerts, which are sent on a wave-length of 1500 metres, the Hague concerts on 1050 metres, the French concerts from "l'École des Postes et Télégraphes" on 450 metres, and the British concerts broadcasted on wave-lengths varying between 350 and 425 metres. Careful and accurate descriptions are given of the components of valve receiving sets, the diagrams can be read at a glance, and the many useful practical hints will be welcomed by amateurs.

Labyrinth and Equilibrium. By Prof. S. S. Maxwell. (Monographs on Experimental Biology.) Pp. 163. (Philadelphia and London: J. B. Lippincott Co., 1923.) 10*s.* 6*d.* net.

MANY different views have been held as to the respective functions of the ampullæ, otoliths, and other constituent parts of the internal ear, and any fresh evidence on the subject must be welcome to physiologists. Prof. Maxwell seems to have attained a high degree of accuracy in his experimental methods, especially in dealing with the otoliths. He shows, for example, that compensatory movements to rotations around the longitudinal and transverse axes continue so long as the otolith of the recessus utriculi remains uninjured. He further shows, in the case of the ray, by mechanical pressure upon the otolith in different directions, that it is the displacement of the otolith and not its own pressure which is the actual stimulus, and that it is the direction of the displacement which determines the direction of the compensatory movement. Unfortunately, his experiments leave us completely in the dark as to the reason for the existence of the three semicircular canals and their highly characteristic orientation.

Radioactivity and the Latest Developments in the Study of the Chemical Elements. By Prof. K. Fajans. Translated from the fourth German edition by T. S. Wheeler and W. G. King. Pp. xvi+138. (London: Methuen and Co., Ltd., 1923.) 8*s.* 6*d.* net.

PROF. FAJAN'S book is particularly addressed to chemists, and it gives in a very readable form the important developments in the study of radioactivity, isotopes, atomic numbers, and the structure of the atom which have been made in recent years. The subjects are dealt with briefly, but in a very authoritative manner, and chemical students will find the book of great interest and value. There are references to the literature and an index. The book is well printed and illustrated. One might have wished for a little more detail of experimental methods (*e.g.* in connexion with Moseley's work, which is not described, whereas Aston's apparatus is figured and explained), but in the limits of his space the author has generally made a wise choice of material. The numerical constants in the tables of radioactive series (pp. 21-23) in some cases differ slightly from those adopted in the Report of the International Commission on the Elements (1923).

Geometry Practical and Theoretical, Pari Passu. By V. Le Neve Foster. In 3 vols. Vol. 3: Solid Geometry. (Bell's Mathematical Series for Schools and Colleges.) Pp. xiv+423-585+viii. (London: G. Bell and Sons, Ltd., 1922.) 3*s.* 6*d.*

THIS is the third part of a work of which we have already noticed the first and second parts (NATURE, June 10, 1922, vol. 109, p. 737). Mr. Foster continues to combine the theoretical with the practical, and added interest is obtained by historical references. The scope of the book is indicated by the fact that it deals with parallelepipeds and tetrahedra, lines and planes, gradients, regular solids, and the sphere. There are chapters on the mensuration of prisms, pyramids, and spheres, as well as on solid angles and Euler's theorem. A concluding chapter on the earth is particularly useful and instructive.

We like this volume very much, and think it makes a most useful and pleasant addition to the available elementary literature on solid geometry. S. B.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Gorilla's Foot.

SIR RAY LANKESTER, in his recent book, "Great and Small Things," makes the following statement in the chapter on "The Gorilla of Sloane Street":

"An entirely erroneous figure of the gorilla's foot is given by Mr. Akeley in the *World's Work* of October 1922. He gives valuable observations on the habits of the gorillas made when hunting this animal in the neighbourhood of Lake Kivu, in Central Africa. He made casts of the head, hands, and feet of specimens killed by him. But the cast of the foot is (as shown in a photograph) strangely distorted, and made to present a false resemblance to the foot of man. Since Mr. Akeley was securing specimens of gorilla for the American Museum of Natural History in New York, it is well that his mistake about the gorilla's foot should be corrected at once."

I have examined the cast of the foot made by Mr. Akeley, who states that the cast was made in the relaxed position after rigor mortis had passed away. There has been no retouching or alteration, and the photographs published in *World's Work* give a very fair representation of it. The foot of Mr. Akeley's old male gorilla undeniably differs in many details from that of John, the young "Gorilla of Sloane Street," and still more from that of an infant gorilla formerly in the New York Zoological Park.

Dr. D. J. Morton, an orthopædist, has recently published an important article on the evolution of the human foot in the *American Journal of Physical Anthropology* (Oct.-Dec. 1922), in which the structural contrasts in the skeletons of infant and adult gorilla feet are shown to be connected with the differences in function and in body weight. Mr. Akeley's old male gorilla foot is amazingly manlike in general appearance; his female gorilla foot shows a distinct peroneus tertius muscle. No doubt the great toe could be more or less abducted from the other digits, but the cast represents the foot as it was in the relaxed condition. There is no evidence from the cast that the foot is "strangely distorted, and made to present a false resemblance to the foot of man."

From a copy of this cast which is being sent to the British Museum (Natural History), English naturalists will have an opportunity of judging whether Sir Ray Lankester's criticisms are justified.

WILLIAM K. GREGORY.

American Museum of Natural History,
New York, September 21.

MY "criticisms" quoted by Dr. William K. Gregory refer to a text-figure published by Mr. Akeley in the *World's Work* of October 1922. As to whether this figure gives "a very fair representation" of the cast of the gorilla's foot made by Mr. Akeley, and what precisely Dr. Gregory means by "very fair," we shall be able to judge when the promised copy of the cast is received at the Natural History Museum. My own experience is that a photographic camera turned on to such an object as the cast of the foot of a dead gorilla will yield a misleading, or even a "distorted," picture if special skill has not been exercised in both the posing and the illumination of the photographed object, and also in the manipulation of the camera.

I should be greatly pleased were Mr. Akeley to demonstrate that the foot of the gorilla from Mount Mikeno is, as he supposes, unlike that of the other adult gorillas long known to naturalists, as well as unlike that of any known anthropoid.

FIG. 1.

Fig. 1 is reproduced photographically from that given by Mr. Akeley in the *World's Work* as representing a cast of the foot of a large gorilla, taken immediately after death. It is unlike any other published figure of a gorilla's foot. I place here beside it the figure of the plantar surface of the gorilla's foot (Fig. 2) as recorded by Mr. Pocock, of the Zoological Society of London. I accept this Fig. 2 as correct. It agrees with all other statements and illustrations prior to that of Mr. Akeley.

FIG. 2.

The explanation of this discrepancy which appears to me probable is that Mr. Akeley's cast of the foot of the gorilla—reproduced here as Fig. 1—has been accidentally distorted, so that the photograph is misleading. It is highly improbable that Fig. 1 corerctly represents the foot of a normal species or variety of gorilla.

Since writing the above, I have received by the courtesy of the publishers—Messrs. Heinemann—advanced sheets of Mr. Akeley's new book called "In Brightest Africa." My opinion that owing to some unfortunate mistake the cast itself of the gorilla's foot figured by Mr. Akeley is defective and distorted is favoured by the photograph, labelled "A Gorilla's Foot and Hand," which faces p. 230 of the new book. This photograph is not taken from a cast but from the actual foot and hand of a dead gorilla. It shows the plantar surface of the foot, and this differs very widely from the same region as shown in the cast under discussion, which is taken

from another specimen. In this new photograph the great toe is large and diverges from the other toes as in my Fig. 2 (here printed). But its terminal phalanx is flexed and the foot is so posed that the great digit projects over and in front of the bases of the other digits and is consequently foreshortened in the photograph. The shape of the plantar surface and that of the heel is *not* that shown in the photograph of Mr. Akeley's cast—but is that already familiar to those who have made a study of the gorilla's foot. It is a happy circumstance that Mr. Akeley presents his readers with conclusive evidence condemning his plaster cast of the gorilla's foot, side by side with the photograph of that misleading production (which faces p. 242). He could not deal more frankly and straightforwardly with the matter than this. E. RAY LANKESTER.

October 5.

Determination of the Temperature of the Upper Atmosphere by Meteor Observations.

IN a letter published in NATURE for February 10, 1923 (p. 187), I referred to the possibility of determining the temperature of the upper atmosphere on any occasions when the disruption of a meteor has been heard and the time interval between sight and sound has been recorded. I have now to report that I have only been able to learn of two instances which have looked favourable, and that neither of them has yielded useful information.

The first case is that of the meteor of December 21, 1876, which is described in the *American Journal of Science and Arts*, Series III., Vol. 13, p. 166, 1877, and in a paper by Prof. C. U. Shepard, on p. 207 of the same volume, as well as in a paper read by Prof. D. Kirkwood before the American Philosophical Society, March 1877. The meteor was under observation from Kansas to the shores of Lake Erie.

Over the State of Missouri one or more explosions occurred, and the disintegration continued until there was "a large flock of brilliant balls chasing each other across the sky." In some places "a terrific series of explosions were heard." It is clear that the identification of the source of any particular sound is out of the question. The following tantalising observation quoted by Kirkwood is therefore of no service: "Rev. James Garrison, who resides one mile south of Bloomington, noticed by his clock the time of the meteor's disappearance and also that of the subsequent rumbling sound, together with the violent jarring of his house. The interval was 15 minutes, indicating a distance of 185 miles." The implication that the speed of sound is a universal constant is to be noted.

The second case is that of the meteor of July 27, 1894, a very detailed account of which is given by Prof. E. S. Holden in "Meteors and Sunsets" (Contributions from the Lick Observatory, No. 5). It is clearly established that the meteor exploded at a height of about 28 miles and near to Merced, California. The determination of the time of passage of the sound to the Lick Observatory appears from the statements of the observers to be precise enough. Five observers who noted the time at which the sound was heard agree within two or three seconds. For the time at which the explosion was seen there is, however, only one observation with any claim to precision.

The time of explosion (A. F. Poole)	7h. 29m. 45s. $\pm$ 10s.
The time of hearing the report (five observers) .	7h. 36m. 14s. $\pm$ 3s.
Time of passage of sound .	6m. 29s. $\pm$ 13s.

The distance from the observatory to the point at which the explosion occurred is estimated by Holden as 59·3 miles—*i.e.* 95 km., due allowance being made for the height of the observatory above sea-level.

The data imply that the average speed of the sound was 244 ± 8 metres per second, and that the average temperature of the air between 28 miles and 1 mile above sea-level was $148° \pm 9°$ A. (about $-193°$ F.).

In 1894 such an estimate was accepted without difficulty. In 1923 it looks wrong. The most likely place for a flaw is in Poole's observation. There is no statement as to how it was made: if with an ordinary watch an error of a whole minute is not unlikely. With the appropriate amendment the time of travel of the sound becomes 5m. 29s., the speed 289 metres per second, and the temperature 207° A.

Some confirmation is found in the only report received by Prof. Holden in which a single observer states the interval between sight and sound of the explosion. Mr. George Bray saw the whole phenomenon at Santa Clara, and gave the interval as 7½ minutes. According to Holden's sketch-map, the horizontal distance was 70 miles, the path of the sound was therefore about 75 miles or 121 km., and the speed 278 metres per second. This corresponds with an average temperature 192° A. and is quite plausible, but with the limitations implied by an estimate of 7½ minutes, little weight can be attached to the result.

I have trespassed so far on your space because I wish to emphasise the fact that any one who has the good fortune to see a meteoric explosion will be doing good service if he notes the time by his watch (writing it down immediately) and listens for the sound. If he is able to compare his watch with a standard clock, so much the better, but from the present point of view the interval is of greater importance.

In conclusion, I should like to thank Miss Williams, assistant secretary of the Royal Astronomical Society, who devoted much time to looking through the literature of meteors on my behalf.

Experiments on *Ciona intestinalis*.

IN the issue of NATURE for November 3, p. 653, there appears a letter from my old friend and former colleague, Mr. H. M. Fox, in which he records an attempt which he made this summer to repeat Dr. Kammerer's experiments on Ciona. These experiments consisted in inducing an abnormal growth of the siphons of Ciona by repeated amputation. Mr. Fox amputated the siphons of Ciona, but the length of the regenerated siphons was normal.

As Dr. Kammerer took a deep interest in the projected repetition of his experiments on Ciona, and wrote to me twice this summer to learn if repetition were being attempted and under what conditions, perhaps you will allow me to make some remarks on Mr. Fox's letter, as Dr. Kammerer is now in America.

Dr Kammerer, whilst in Cambridge, wrote out a full account of the precautions to be observed in making these experiments. At that time he did not know that Mr. Fox was going to take up the work: another Cambridge biologist had undertaken to do so, but this gentleman was prevented by illness from doing the work. To him, however, Dr. Kammerer had transmitted his information. I understand—Mr. Fox will correct me if I am wrong—that Dr. Kammerer's instructions did not reach Mr. Fox.

In these circumstances it is not surprising to learn that Mr. Fox failed to obtain Dr. Kammerer's results, since he has tumbled into one of the most obvious pitfalls. It may surprise him very much to learn that *Dr. Kammerer got the same results as he did* when, like Mr. Fox, he cut off only the oral siphon. Since the anal siphon remains of normal length and the reaction is of the animal as a whole, the regenerated oral siphon is of normal length also. But *when both anal and oral siphons are amputated in a very young animal*, then long siphons are regenerated. I have a photograph which shows an operated Ciona and a normal one growing side by side in the same tank, and the contrast between the lengths of their siphons is obvious. When Dr. Kammerer returns from America I hope that Mr. Fox will communicate with him and repeat the experiments, observing Dr. Kammerer's precautions, when, I feel confident, he will obtain Kammerer's results.

My confidence is based on the following considerations. Curt Herbst in Germany tried to repeat Dr. Kammerer's experiments on *Salamandra maculosa*; he arrived at the conclusion that although the animal may change colour with environment, yet these changes are temporary, and that therefore it was useless to try to repeat Kammerer's work on the inheritability of these changes. Herbst worked principally on Salamander larvæ. Mr. E. Boulenger in 1919, however, began to repeat Kammerer's work on young metamorphosed Salamanders. I have been privileged to watch Mr. Boulenger's experiments from the beginning, and now in 1923, after four years' work, Mr. Boulenger and I are both convinced that Kammerer is perfectly right so far as the first generation is concerned. Our specimens are not yet, unfortunately, completely sexually ripe. E. W. MACBRIDE.

Globular Lightning.

I AM much interested in the references to lightning in Dr. A. Russell's presidential address to the Institution of Electrical Engineers, and also in the article by Dr. G. C. Simpson in NATURE of November 17, especially where the latter mentions that "the only physical phenomenon yet produced in a laboratory at all approaching ball lightning is the active nitrogen studied by Lord Rayleigh."

It has occurred to me that possibly the ball may be a mass of concentrated nitrogen oxides, and I suggest this because the observations seem to fit in well with the formation and action of such gases.

We know that when air passes through high-tension arc flames in an electric furnace, the nitrogen and oxygen combine to make nitric oxide gas, and that as the gas cools down it takes up more oxygen to form nitrogen dioxide, the speed of combination increasing rapidly with the cooling.

In Norway, and elsewhere, for many years, electric furnaces have been running which aggregate over half a million horse-power and make nitrates from the air in the same way that lightning does. It has been estimated that 100 million tons of nitrogen fixed by lightning flashes fall annually on to the earth's surface.

The energy suddenly released by a flash is enormous, and the potential has to be many millions of volts to tear a way, or a hole, through the air dielectric. May it not be that a very high pressure is suddenly set up, followed by a sudden reaction and chilling effect? If so, then the conditions are extremely favourable to the production of a large amount of nitric oxide and nitrogen dioxide gas in a very concentrated and possibly liquid form.

Whilst moving through the air the outer layer of the gas will gradually oxidise to nitrogen dioxide, which will dissipate, and if the length of travel through the air is long enough it may all dissipate in that way. Occasionally, however, a ball of gas may start from a point so near the earth that some of it is still in concentrated form when it arrives at earth-level.

If a ball of such concentrated gas meets with organic material, such as a haystack or a tree, it would immediately nitrate it and a violent explosion take place. One of the worst accidental explosions that took place in Germany during the War is said to have been caused in that way.

The peculiar smell, which some observers have called "sulphury," may be nitrogen oxides or ozone.

Of course, the point most difficult of explanation is how the gas, if such it be, becomes concentrated into a ball. Perhaps a reader of NATURE can suggest an explanation of that point.

E. KILBURN SCOTT.

38 Claremont Square, London, N.1.

Principles of Psychology.

AN absence from London prevented me from seeing the review that appeared in NATURE of October 13, p. 535, under the heading "Mental Athleticism," of my work "Principles of Psychology"; but I desire now to enter my protest against the ill-usage offered to my book, and to science itself.

I do not speak from mere author's vanity, for I have written this book not for my own glorification, but by way of introducing something into the world of thought that will eventually impinge on every fibre of our civilisation and help to mould the life of man to greater purposes.

When as a young student I set forth with this purpose, *por mares nunca de antes navigados*, I resolved to stake my own intellectual life on the issue, and not to write a line until I had completed the exploration of my problem. That work occupied twenty years of secluded work and intense intellectual effort.

If I am confident now, it is as Pythagoras was confident, for the good reason that he had furnished the complete demonstration of what others had tentatively sought to know.

The review, published anonymously in NATURE, contains a series of statements so wide of the mark as to seem to be almost purposely misleading. My first book did not, as the reviewer suggests, fall stillborn from the press; the whole edition has, in fact, been sold. It is true that by certain "authoritative teachers" here it was received with sneering comment, but it found the most gratifying acceptance in enlightened quarters. The *Revue Philosophique*, which is the most authoritative of all the philosophical magazines, broke its rule of allotting but one page to a review, and devoted to the book twelve times that space in a finely analytical study by Prof. Dugas, himself justly famous in Europe.

So far from finding with your critic, in his incomprehensible statement, that "the solution offered as new is certainly not novel," Prof. Dugas noted especially the "originality" as well as the "profundity" of the work. Of the present volume he says: "I live with your *Principles* just now. . . . I am more and more struck by the philosophic character of your psychology." Amongst many others Ribot and Boutroux, both world-renowned, expressed themselves in similar terms. Boutroux was "astonished"

at the scope of the book, and declared, "the conception is as scientific as the exposition is lucid."

I mention these, for I recognise that in academic circles here it is the custom to "drink the label," but I give no value to mere authority; I attach the utmost importance, however, to the serried march of my own arguments proceeding from the deepest ascertainable base in regular succession to the conclusions offered.

Would any one guess from the statements of the reviewer that this presentation of psychology, so far from depending on my personal feelings, is entirely objective in conception, and that I do not ask the reader to take my series of "Fundamental Processes" at my word, but offer the demonstration of their "necessity and sufficiency" in an exposition of which the meticulous and exhaustive character may be excused only by the paramount desire for rigour?

The reviewer is wrong even when he attempts to soften a disparaging note: "The choice of the name [Alétheian system] seems to imply a slight on other systems, but probably nothing of the kind is intended." What I intend to imply is that this work stands to other systems in a relation corresponding to that of Pasteur to the writings of the physicians of Louis XIV., or that of Galileo to the Schoolmen who discussed phenomena by talking of "proper" and "improper" motion, and decided questions not by illuminating from the foundation but simply by appealing to academic shibboleths.

That, too, is the meaning of resting my hope, not on "the young" as your critic cautelously insinuates, but on uncontaminated and capable young minds.

ARTHUR LYNCH.

80 Antrim Mansions, Haverstock Hill, N.W.,
October 30.

COL. LYNCH'S complaint of ill-usage to his book in the review in NATURE amounts to a charge that the reviewer has failed to appreciate the originality and the scientific importance of the author's system of psychology. This charge is true. All I can do is to assure your readers that I wrote without consciousness of prejudice, and only after a thoughtful reading of the book and sincere attempt to discover the author's meaning. I respect the author and had no intention of giving offence.

I am surprised and sorry that my reference to the author's former book is resented. May I say that the playful, not spiteful, allusion to the reception of the greatest philosophical book of the greatest British philosopher, Hume's "Treatise of Human Nature," was not meant to bear any reference to financial matters. Col. Lynch says that the whole edition of his former book has, in fact, been sold. I am glad, but I had no thought about it. Possibly Col. Lynch does not know that the whole edition of Hume's book was sold and that he was not smarting under financial loss when he said that it had "fallen still-born from the press."

THE REVIEWER.

Psycho-Analysis and Anthropology.

DR. MALINOWSKI'S illuminating letter in NATURE of November 3 contains a reference to what he rightly calls my "harsh judgment" upon Freud's incursion into ethnology. But he has not made it clear that I was criticising the views expressed in "Totem and Taboo" and not Freud's teaching as a whole. For I am in complete agreement with the latter part of Dr. Malinowski's letter, in which he insists upon the value of Freud's reform in psychological method for the solution of anthropological problems.

The examples quoted by Dr. Malinowski himself illustrate the aspect of Freud's work which is not merely fallacious but also in conflict with the essential part of his own teaching. Moreover, Freud entered the ethnological arena without preparing himself for the fray by making himself acquainted with the facts he attempts to explain. No one with any knowledge of the practices of totemism, exogamy, and taboo, can fail to recognise that Freud is unacquainted with the essential facts and associations of these remarkable customs, and that his suggestions as to their origin are irrelevant and nonsensical.

The essence of Freud's reform in psychological method was his insistence upon the fact that all the vagaries of behaviour and belief, the phantasies of the sleeping and waking life, had definite causes, which could be discovered and traced back to their real source in the individual experience of each of his subjects. But after exploiting this method of analysis of individual experience up to a certain point, Freud suddenly changes his tactics and quite inconsequently postulates a "universal symbolism," into conformity with which he tries to force the incidents of each individual's distinctive experience. This appears to me to be in direct conflict with the essential feature of his theory and practice. Moreover, this speculation of "universal symbolism" is responsible for most of the unsavouriness of Freud's methods which have excited such violent antagonism, and I believe not without some measure of justification. It is the duty of those who appreciate the value of the really fundamental part of Freud's reform to expose the inconsistency of these accretions which imperil the whole doctrine.

The criticism of his adventure into ethnology is inspired not only by the realisation of his lack of knowledge of the subject, but also by the fact that it is the more than doubtful and inconsistent part of his psychological teaching which he proposes to use as a panacea for the cure of ethnological difficulties. At a time when the ethnological doctrine of "psychic unity" is at its last gasp, Freud comes along with the fantastic nostrum of "typical symbols" and tries to revive it.

In the *Monist* of last January, I have analysed the claims made by Freud in "Totem and Taboo," and exposed their futility. But as even the qualified support Dr. Malinowski accords to this aspect of psycho-analytic method involves a very grave danger to anthropology, I have repeated here some of the arguments set forth in greater detail in that criticism.

G. ELLIOT SMITH.

The Origin of Petroleum.

I HAVE read, with much interest, the article on the "Origin of Petroleum" in NATURE of October 27, p. 627.

In a discussion of this nature one of the great difficulties, as mentioned by Mr. Cunningham-Craig, is for geologists and chemists to meet on common ground. This applies, for example, to a point raised in the article in NATURE as well as during the discussion at the Institution of Petroleum Technologists, in the words to "formulate any one hypothesis to explain the formation of such complex mixtures as mineral oils, and still more difficult to account for the great diversity in chemical composition exhibited by mineral oils from different localities." Considering coals as analogous, are not the chemical and physical variations between lignite and anthracite fully as great as those found throughout the range of petroleums? Yet no one casts doubt on the vegetable origin of coal on the score of the almost infinite variety of coal.

In the case of petroleum, formed from the same raw material, in itself extremely variable, other subsequent variables enter; one is the extreme delicacy and susceptibility of both the forming and formed petroleum to ever-continuous changes of temperature and pressure within the earth's crust; and the other is that petroleum can in general definitely be proved to have migrated at least several thousand feet, and during this process it may undergo chemical alteration, especially during contact with catalysers. In forming oil in the laboratory the principal variables at the disposal of the chemist are temperature, pressure, and catalysers; by varying these he obtains widely differing products from the same organic matter. In Nature, with infinite time added to the list of variables at present known, we seem to me to be not only fully justified but utterly unable to avoid expecting an almost infinite variety of petroleums.

I believe it has now been recognised that cholesterol and phytosterol are not necessarily any criterion as to animal or vegetable origin, since both can be made from a number of raw materials.

It is difficult to limit remarks on a subject so wide and important, but in conclusion I should like to make one further comment. Petroleum in the making at surface has been mentioned in various parts of the world, but these reports are frequently due to faulty observation or untenable hypotheses, and Djebel Zeit, Egypt, is no exception. I think all geologists are agreed that the oil there is, at latest, Miocene, and most probably of Cretaceous age, and that its presence in the corals is due to submarine and shore seepages, some of the oil from which lodged in the porous corals, and that on the local evidence it cannot possibly be explained by formation *in situ*.

The Ralline Genus Notornis, Owen.

The ralline genus Notornis was established by Sir Richard Owen in 1843 upon a series of bones sent him from New Zealand by the late Mr. Walter Mantell, in one of the earlier consignments of Moa bones discovered in the sand-dunes where the Maoris feasted. Owen designated his type species *Notornis Mantelli*. In the course of determining a collection of ornithological remains from turbaries, caves and kitchen middens from New Zealand and the Chatham Islands, containing many relics of those birds, I was bewildered, a few days ago, by discovering that this long-established genus had been boldly superseded by Messrs. Mathews and Iredale in their beautiful work on the "Birds of Australia," by the new generic designation, Mantellornis—one of the numerous topsy-turvies their volumes contain.

In 1843 Notornis was supposed to be an entirely extinct rail. After the lapse of many decades, however, more than one specimen has been obtained in the flesh, an example of which, known to zoology for some thirty years as *Notornis hochstetteri* of Meyer, is now preserved in the Dresden Museum. This specimen was dissected by that distinguished biologist, the late Prof. Jeffery Parker, who found it, in its osteological details, so closely affine to *N. Mantelli* as to cause him (as he told me) much doubt as to its differing in any character from Owen's species. The authors above cited have now renamed the Dresden specimen *Mantellornis hochstetteri* for the sole reason that Owen's genus was founded on *fossil* bones—after all not really fossil. It must now be equally legitimate for the next daring Neozealandian systematist to follow this example and assign a new genus, say Iredalornis, to the Apteryx bones occurring in New Zealand pleistocene and more recent deposits, and in caves and cooking-ovens, the minutest anatomical details of which agree with those of the Kiwis living within sight of the scenes in which their very own parents perished—a violent breach of the Rules of Nomenclature not less unscientific than the substitution of Mantellornis for Notornis.

It seems to be coming to this, if we are to be guided by these extremist authorities on nomenclature, that the very same creature is to be assigned to one genus when it is studied from the inside, and to another when (found alive) it is studied from the outside. Against such absurd genus-making—than which no more glaring example has surely been perpetrated in any reputable zoological publication—I, for one, desire to enter my strongest protest, in the interests of biological science, and against the confusion that must inevitably result if such procedure, as is described in this letter, is to be followed.

Henry O. Forbes.

Redcliffe, Beaconsfield, Bucks,
October 28.

Dr. Jesse W. Lazear and Yellow Fever.

The story of the death of Lazear as commonly told is that mentioned in Nature of October 27, p. 631, namely, that he "allowed himself to be bitten by mosquitoes that had fed on the blood of yellow fever patients." It may, however, be worth while to state that the mosquito-bite which killed him was inflicted, not experimentally, but by a "wild mosquito" in the ward in which he was working (September 1900). This was told to me in Panama in 1904 by Dr. T. C. Lyster, who was actually with Lazear when the insect bit him on the hand; and Lazear then remarked, "I wonder whether this creature is infected"—or words to that effect. It was Dr. J. Carroll, who had been previously, and experimentally, infected by mosquitoes fed on yellow-fever patients; but he recovered. Nevertheless, Lazear's case was almost as good as an experimental one. The whole heroic story will be found set forth in Dr. Howard A. Kelly's "Walter Reed and Yellow Fever" (The Norman, Remington Company, Baltimore), and is given briefly in my Memoirs, p. 425.

Ronald Ross.

Life History of the Ephemeridæ.

I have been asked by a French observer, M. A. Gros of Marigny (Jura), France, if I can put him into touch with entomologists interested in the Ephemeridæ. M. Gros is the author of an illustrated brochure, "Études sur les premiers études des éphémères du Jura français," which deals mainly with *Ecdyonurus forcipula* of Central Europe—not, I believe, found in the rivers of the British Isles. M. Gros would prefer to correspond in French if possible. He appears to have established some interesting facts, which may help us in our endeavours to transplant water-flies from one river to another. So many causes are denuding our rivers of their natural supplies of Ephemeridæ, etc., that it is most important to introduce fly from other waters if possible. It has been done, at least temporarily, in a few instances.

October 29.

Natural History in Kinematography.

THE value of the kinematograph as a means of obtaining permanent graphic records of phases of animal movement, and of the various stages of growth and change of form that go to make up the story of the life-history of insects and other invertebrates, is, at long last, becoming more generally appreciated; while to find a British firm devoting its energies entirely to the production of such films is an encouraging sign of the growth of public interest in the pictured story of animal life. The British Instructional Films Ltd., the firm in question, has started the issue of a series of remarkably interesting natural-history films under the general title of "Secrets of Nature," which we are glad to hear will be shown as part of the regular programme at kinematograph theatres in London and the provinces. This is a step in the right direction, and should help further to demonstrate the importance of the kinematograph as a means of popular instruction.

FIG. 1.—Imago of mayfly just emerged from sub-imago stage, showing cast skin, which is waterproof to enable it to escape from water.

The subjects included in the series cover a fairly wide range, and should appeal not only to all who are interested in bird and insect life, but also to the lover of the open countryside and the wild life of field and hedgerow, to the antiquary, and to the angler. There is a wonderfully complete film of the life-history of the Mayfly that must have cost an infinite amount of patience and care to obtain; a reproduction of one of the pictures is given in Fig. 1. This is appropriately followed by a still more striking record of spring salmon-fishing in Scotland amidst the most picturesque surroundings (Fig. 2). In the latter film, use was made of the ultra-rapid kinematograph camera to obtain for the first time a complete record of fresh-run salmon ascending the waterfalls and rapids in their journey up stream to their spawning grounds. By means of the ultra-rapid camera it is possible to take records at as much as eight to ten times the normal speed, so that, given sufficient light for the extremely short exposures entailed, a film may be obtained of every phase of the swift rush and leap of the fish; movements too rapid for the eye to follow or appreciate. These ultra-rapid records are projected on to the screen at the normal rate at which kinematograph films are shown, namely, at sixteen pictures a second, which enables the observer to follow clearly every detail of movement; and the lightning-like dart and leap of the fish passes across the screen as a slow and amazingly graceful series of movements.

Watching these perfect pictures, one cannot help thinking of those early pioneers of chronological photography, Marey and Muybridge, and of how much they would have given to have had at their disposal such apparatus for taking their records of trotting horses and running men. There can be no doubt that this latest development of the kinematograph will prove of invaluable service in the critical analysis of movement. During the past summer there have been taken in the Zoological Society's Gardens at Regent's Park several extremely interesting records with this apparatus, including the movement of the long tongue of the chamæleon, the forked tongue of a python, and the Barbary sheep descending the almost vertical sides of the high rocks in their enclosure in the Mappin Terraces.

Another subject included in the series will undoubtedly arouse considerable interest, for it has an historical as well as a biological aspect: that is the film record of the story of Westminster Hall and its wonderful roof. This film was taken under the direction of

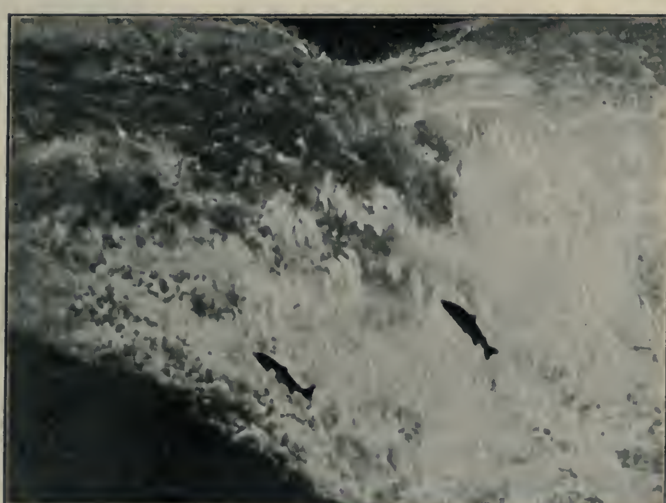

FIG. 2.—Salmon ascending a waterfall on their way to their spawning ground.

Sir Frank Baines, and shows not only the work of restoration in progress, but also the actual cause of the threatened danger to the venerable roof, the larvæ of the deathwatch beetle at work excavating its galleries in the heart of the old oak beams (Fig. 3). The film of the gallant little three-spined stickleback engrossed in the domestic duties of nest-building (Fig. 4), enticing the female to deposit her eggs therein, and then

mounting guard over the spawn, and later protecting the newly-hatched fry from marauding visitors (Fig. 5),

FIG. 3.—Larva of deathwatch beetle eating into roof-timbers of Westminster Hall.

is an ideal nature study subject which is bound to rivet the attention of every boy who has the good fortune to see it. One can but hope that in the near future this class of film may become a regular feature in the programme of the kinematograph theatres throughout the country, and ultimately replace much of the vulgar trash and sordid themes that at present occupy far too prominent a place on the bill.

The production of these natural-history films is by no means a simple matter, for if they are to be of real educational value, not only must the record show the subject clearly, but also they should be taken by, or under the direct supervision of, one who is thoroughly conversant with the habits, characteristic movements, and life-history of the creature, so that no important phase is missed or wrongly interpreted. This the British Instructional Film Company appears fully to have realised, their films having been taken and edited by a band of acknowledged experts. The actual taking of these records of animal life calls for great technical skill and judgment and for the exercise of untiring patience, for the difficulties to be surmounted are infinitely greater than in ordinary photography. Hours of patient watching and waiting have to be faced, and often when the end seems in sight something will happen; the stock of film in the camera runs out, or the sky becomes too overcast to permit of sufficient light for the extremely short exposures necessary, and the final stage is missed—perhaps the last possible chance of the season, and the whole of the work has to be begun all over again the following year. "Light, more light!" is the constant prayer of the naturalist kinematographer, for he must be able to obtain sixteen fully exposed little film negatives per second if his record is to give an approximately truthful screen picture; while to catch every stage in a swift movement like the leap of a salmon or the beat of an insect's wing, the sixteen pictures may have to be quadrupled at least.

Although the photographic emulsion with which the celluloid film is coated is very fast, the need for such extremely short exposures renders it necessary to employ lenses working at very large apertures, at F.2, or F.3, if sufficient light is to reach the film. Consequently, the depth of field that will be critically sharp when working close up to the subject, as one has to do when recording the movements of small insects, will be limited practically to a few inches, necessitating constant most careful readjustment of the focus, should the creature approach nearer to the camera or elect to move further away; while owing to the enormous subsequent enlargement of the picture when projected on the screen, every detail must be recorded on the negative film with microscopic sharpness. Last, but by no means least, the subject, if a bird or a mammal, has to be accustomed to the presence, and the sound when in operation, of the kinematograph camera; this often calls for considerable patience, for all wild creatures are suspicious of unfamiliar objects or sounds.

FIG. 4.—Male three-spined stickleback clearing ground preparatory to building nest.

FIG. 5.—Nest completed, and female depositing spawn, while male guards the nest.

Even in captivity, this inborn mistrust and uneasiness in the presence of an unfamiliar sight or sound is main-

tained, and may result in agitated, unnatural movements, giving a totally false impression of the true natural characteristics of the animal.

This has been demonstrated on several occasions in making records of some of the shyer animals in the collection of the Zoological Society of London. In obtaining successful records of the rare and interesting maned wolf of South America, the kinematograph apparatus had to be set up again and again and the mechanism run without any film, before the animal could be induced to tolerate its presence or move about in a natural manner. On the other hand, the anthropoid apes, like children of the human race, are so intensely curious and interested in what is going on, that they will cease playing about in their normal fashion until they have been permitted thoroughly to examine the apparatus and satiate their curiosity.

We are indebted for the accompanying illustrations to the directors of British Instructional Films Ltd., 26-27 D'Arblay Street, Wardour Street, London, W.1.

Meteorological Perturbations of Sea-Level.

By Dr. A. T. Doodson.

It is always understood that the predicted heights of high and low tidal water do not take into account the variations in the height of the sea due to wind and to air-pressure, and that the errors due to these causes may be of considerable magnitude. With the large ships that are now in common use the margin between sea-bottom and ship-bottom is small, and since many of the largest ports in the world are situated in comparatively shallow water, navigation, both in channels and into dock, is carried on only with constant reference to the state of the tide. A particular example of the problem is that of loading a vessel in dock: how much cargo must be left on the quay-side so as to leave sufficient clearance for the vessel to get safely out of dock? The cargo so left has afterwards to be transported by lighter, with consequent increase of expense. If the tide is lower than was expected there is increased risk to the vessel, and if the tide is higher than was expected needless expense has been caused through leaving cargo to be transported by lighter. It is therefore obvious that a forecast of the effects of wind and air-pressure on sea-level and tides would be of very great advantage to navigators in and near a port, and for this reason much attention has recently been given to the subject.

The effects of wind and air-pressure on sea-level are also important factors for engineers engaged in the construction of harbour works. Again, they are of importance in connexion with geodetic surveys, since sea-level is an obvious datum from which to take measurements; but it has been shown by the Ordnance Survey ("Second Geodetic Levelling of England and Wales," p. 34) that measurements by levelling gave mean sea-level at Dunbar and Liverpool respectively 0·8 ft. and 0·4 ft. higher than at Newlyn. These discrepancies cannot be attributed wholly to errors of levelling, and there is reason to believe that part of the explanation is connected with climatic causes. Investigations as to the variation of sea-level with wind and pressure have been made by Mr. H. L. P. Jolly, of the Ordnance Survey, and are referred to below.

Most investigations on this subject have been concerned with air-pressure and not with wind, the sea being regarded as a negative water barometer; the "constant" for the barometer, however, varies much from place to place, and even according to the numerical method used in obtaining it. A British Association Committee in 1896 reported that the effects of wind and pressure were real, but no law could be established; the methods of investigation, however, were faulty. A successful reduction to law for both wind and pressure in connexion with tides at Ymuiden was published by Ortt in 1897, his method being to collect together observations for given ranges of values of pressure, wind direction, and strength. This method has been used, in essence, by other continental workers. Prof. R. Witting (Bulletin de la Société de Géographie de Finlande, Fennia, 39, No. 5, 1918) has elaborated a method of comparing the gradients of the sea-level in the Baltic Sea with the gradients of the pressure-system over the sea; this method is strictly in accordance with theoretical considerations, but it requires a large number of observing stations, and is most confidently applied to narrow seas. His use of pressure gradients instead of wind-strength and direction of wind is very commendable, and was utilised by Mr. Jolly in his investigations, leading to the simple formula

$$\zeta = \kappa(B - \bar{B}) + \lambda(E - \bar{E}) + \mu(N - \bar{N}),$$

where ζ is the meteorological disturbance of sea-level; B, E, N are the values of the local barometric pressure and its gradients to the east and north respectively; bars denote means in the interval of time considered, and κ, λ, μ are constants determined from observation.

This formula is valuable because it lends itself very easily to numerical methods, and fairly accurate values of the constants may be obtained from observations extending over only a month, whereas an elaborate method like Ortt's requires far more observations and much more labour. It represents the perturbations of mean sea-level with a fair degree of accuracy.

The formula has been used extensively at the Tidal Institute at Liverpool, and has yielded some very interesting results. It is easy to deduce from it the direction of the most effective wind for raising sea-level at the place considered, and this has been evaluated from a month's observations at various places on the British coast, the results being illustrated in Fig. 1. The arrows give the direction from which the most effective winds blow, and the lengths of the arrows are proportional to the effects for a given strength of gradient in the most appropriate direction. Many previous investigators dealing with the perturbations of mean sea-level on the Continental coast of the North Sea have found that the most effective winds for raising sea-level there are those which blow towards

the shore, and conclusions have been formulated that the effect is due to the local wind blowing the water towards the shore. This conclusion is not substantiated by Fig. 1, for the winds which raise sea-level on the east coast of Britain are those which blow away from the shore. A westerly wind therefore raises the water of the whole of the North Sea in some degree or other, and this effect must therefore be due to wind blowing over a large area to the north of Scotland. The direction of the most effective wind at Felixstowe has a much larger northerly component than is present at Dunbar. In other words, a northerly wind would have little effect at Dunbar as compared with Felixstowe, the reason probably being that the sea becomes shallower towards the south, agreeing with theoretical conclusions that, apart from the effects of rotation, wind operates more effectively in shallow water than in deep water.

FIG. 1.—The most effective winds for raising sea-level round the British Isles.

The Irish Sea gives some interesting results. It would appear that from Newlyn northwards the most effective wind has a large southerly component. Local influences are far more marked at Newlyn and Cork than at Holyhead and Belfast, while the effect of the broadening out of the Irish Sea is shown slightly at Holyhead and still more at Liverpool, where the westerly component of the wind shows its influence, and again the shallower water of the upper part of the Irish Sea helps the effect.

Some of these conclusions could have been formulated roughly from qualitative statements in seamen's almanacs, but what gives value to the results dealt with above is that they are expressed quantitatively. Further, qualitative statements are liable to give not the most effective wind for a given wind-strength, but that wind which has happened to give a storm-effect.

The predominating factor in the above results is the southerly wind operating on the Atlantic water south of Ireland. This conclusion has been verified for Liverpool by applying an extension of the formula so as to include Atlantic winds (south of Ireland) as well as local winds. The results show that, for a given wind-strength operating in the most favourable direction in each case, the Atlantic wind has 50 per cent. more effect than a local wind, in spite of the deeper Atlantic water being less favourable to wind effects. Further, the most effective Atlantic wind blows from the south and the most effective local wind from almost due west.

When we correlate the pressure system at a fixed time with the mean sea-level at a variable time we find that the correlation between the sea-level at Liverpool and an easterly gradient of pressure, corresponding roughly to a south wind, is greatest when the mean sea-level is taken about fifteen hours later than the corresponding pressure gradient. The corresponding time for Newlyn is nine hours. For a northerly gradient, however, the time difference for maximum correlation with mean level at Liverpool is practically zero. These results are in conformity with those just discussed, for we should expect a large time-interval for setting up the circulation of water from the Atlantic and a small time interval for effects generated in the Irish Sea.

It can be deduced, therefore, that the most favourable conditions for giving exceptional effects on sea-level are those in which a south wind blows for some hours, filling the Irish Sea as a whole, and then changes to the west—the rapidity with which the west wind operates is apparently favourable to storm-effects.

The correlation between mean level at Liverpool and the fluctuation of the local atmospheric pressure is greatest when the sea-level is taken about three hours earlier than the pressure. For Newlyn the time-advance is five hours. These results are of very great interest: the anticipation in mean sea-level of changes in barometric pressure is probably due to the different rates of travel of disturbances through air and through water. Ferrel (U.S. Coast Survey, Report, 1871, p. 93) in 1871 noted that the changes in sea-level in Boston Harbour, U.S.A., appeared to anticipate the barometric pressure. Anticipation of coming storms, according to Dr. Bell Dawson (Trans. Roy. Soc., Canada, 1909, pp. 186-188), is also shown in the currents off Newfoundland; a change in magnitude and direction is noticeable some twelve hours before the onset of a storm, and generally (with some exceptions) the current sets more strongly towards the direction from which the wind is about to blow. This phenomenon is regarded by the local fishermen as an unfailing indication of bad weather. These anticipatory effects are worthy of fuller investigations.

Current Topics and Events.

THE Royal Swedish Academy of Sciences, Stockholm, has awarded the Nobel prize for physics for 1923 to Dr. R. A. Millikan, director of the Norman Bridge Laboratory of Physics at the California Institute of Technology, Pasadena, and the Nobel prize for chemistry for 1923 to Prof. F. Pregl, professor of applied medical chemistry in the medical faculty of the Karl Franzens University, Graz, Austria. Dr. Millikan is best known for his work on the determination of the absolute value of the charge of the electron. Before his experiments various measures had been made of this, by condensing a cloud on free electrons in a gas and observing how the cloud behaved. Millikan found that it was possible to watch the single drops, and thus discovered many inaccuracies to which the earlier work was subject, and this enabled him to modify it into a method of precision. In his final arrangement, a small drop of oil or mercury was watched in a microscope as it slowly fell under gravity or, acquiring a charge, rose in an electric field. In this way he could observe directly the atomic nature. of electricity; for if the speed of the drop ever changed it would always change by a discrete amount In the course of these experiments he worked out the problem of the motion of a sphere in a viscous fluid, and found under what conditions Stokes's law is verified; more recently he has made his work throw light on the nature of the collision of a gas molecule with a solid or liquid surface. It is a fairly safe prediction that it will be long before methods are devised which will give more accurate values than Millikan's for the electronic charge and the associated constants. Only second in importance is his very accurate determination of the quantum by means of the photoelectric effect. His work not only completely verified the Einstein theory, but also showed that the "limiting potential" of that theory is identical with the ordinary contact potential. Since then Dr. Millikan has added a great deal to our knowledge of the spectrum in the region of very short waves.

THE London School of Tropical Medicine, cooperating with the New Zealand Government, has just sent an expedition to Samoa to study the depopulation of the Pacific from the medical point of view. The expedition is led by Dr. Patrick Buxton, and will probably be in Samoa about two years. It is proposed to select a small island and try to exterminate *Aedes variegatus* (*pseudo sentellaris*), the particular mosquito which carries filariasis: a majority of the natives are infected with this disease. This large-scale experiment should afford information about costs and methods, and will be of value in many parts of the world. An investigation of all biting insects will be made, and the party is equipped to study the problems of ventilation and temperature in various types of house. An effort will be made to collect insects in general, even those of no economic importance, because it is presumed that a peculiar fauna still exists in the virgin forests which cover the centres of the islands, and that this fauna is in danger of being exterminated by enemies introduced from other islands.

WITH the December issue the monthly publication of the meteorological ocean charts ceases. The information supplied on the back of these charts will in future appear in a monthly magazine entitled the *Marine Observer* which will be on sale by the Stationery Office. The magazine will be supplied free to the commanders of all ships on the list of regular observers to the Meteorological Office. The face of the charts for each month of the year, with information which is of a permanent nature, have been printed in limited numbers, and one set will, we understand, be supplied, according to its trade, to each ship on the list of regular observers, on request being made by the commander. These charts of frequencies and normals of the North Atlantic or East Indian Seas for each month of the year may be purchased at one shilling each from the Admiralty chart agents. The December issue of the East Indian chart contains a useful index to the information published on the back of the charts from 1906 onwards.

THE many friends of Sir Arthur Schuster will learn with much regret that a few days ago he met with an accident which may lead to the loss of sight of one of his eyes. It appears that he was accidentally struck by a golf-club while standing near a lady player, the result being that his glasses were broken and a piece of glass entered one of his eyes.

THE selection committee of the Harrison Memorial prize, which, in accordance with the trust deed, consists of the presidents of the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry, and the Pharmaceutical Society, will meet shortly to consider the first award of the Harrison Memorial prize. The prize, of the value of about 150*l.*, is to be awarded to the chemist of either sex, being a natural born British subject and not at the time over thirty years of age, who, in the opinion of the selection committee, during the previous five years has conducted the most meritorious and promising original investigations in any branch of pure or applied chemistry and published the results of those investigations in a scientific periodical or periodicals. Provided that in the opinion of the selection committee there is a candidate of sufficient distinction to warrant an award of the prize, the first award is to be made in December next. The selection committee is prepared to receive applications, nominations, or information as to candidates eligible for the prize, which must be addressed to the president of the Chemical Society, and should reach Burlington House, Piccadilly, London, W.1, before December 10.

ON November 14, Prof. R. A. Peters delivered his inaugural lecture as Whitley professor of biochemistry in the University of Oxford. Speaking of the interchange of teachers between Oxford and Cambridge, which he thought was to the advantage of both Universities, he directed attention to the fact that Oxford had inclined to the synthetic and Cambridge to the analytic aspect of biochemistry. The "steam-

engine" view of the body has been proved inadequate; nutrition cannot be expressed in terms of calories. The proteins of food enter the blood as amino-acids; the body forms its own proteins. The connexion between "miners' cramp" and the loss of salts is well established, and gives promise of further light on other morbid conditions. Increased cleanliness in food has tended to cause a deficiency in vitamins. Bread and rice have both suffered in this respect, but under civilised conditions the deficiency can be made up in other ways. A new importance to physiological chemistry is given by the discovery of the functional activity of endocrines. A large audience, including the Vice-Chancellor, was present at the lecture.

WE learn from the *Belfast Evening Telegraph* of October 24 that a new Naturalists' Field Club, styled the "Route," has been founded for northern Antrim, and that it is affiliated to the Belfast Club. The latter now numbers 703 members, and has been described by those who derive much mental profit from its various meetings and excursions as a second university for Belfast. It has the advantage of retaining as advisers members who have watched and fostered its progress for more than fifty years.

IT is announced in *Science* that Mr. John D. Rockefeller, Jr., has given 100,000*l.* toward the endowment fund of 400,000*l.* required by the New York Zoological Society, and will contribute a further 100,000*l.* as soon as the society raises another 200,000*l.* Mr. Edward S. Harkness has given 20,000*l.* and the estate of Mrs. Frederic Ferris Thompson 10,000*l.* For some time the Society has been carrying educational, philanthropic, and civic burdens far beyond its financial resources. Mr. Rockefeller's gift is without restrictions and the income becomes immediately available.

NOTIFICATION is given by the Chemical Society that applications for grants from the society's research fund (made upon forms obtainable from the Assistant Secretary, Burlington House, W.1) must be received on or before Saturday, December 1. The income arising from the donation of the Goldsmiths' Company is to be more or less especially devoted to the encouragement of research in inorganic and metallurgical chemistry; the income from the Perkin memorial fund is to be applied to investigations relating to problems connected with the coal-tar and allied industries.

THE following officers have been elected by the London Mathematical Society for the session 1923–1924:—*President*: Prof. W. H. Young; *Vice-Presidents*: Prof. L. N. G. Filon, Prof. H. Hilton, and Prof. A. E. Jolliffe; *Treasurer*: Dr. A. E. Western; *Secretaries*: Prof. G. H. Hardy and Prof. G. N. Watson; *Other Members of the Council*: Mr. J. E. Campbell, Prof. A. L. Dixon, Miss H. P. Hudson, Prof. G. B. Jeffery, Prof. A. E. H. Love, Mr. E. A. Milne, Mr. L. J. Mordell, Mr. F. B. Pidduck, and Mr. F. P. White.

VISCOUNT LONG OF WRAXALL has accepted the presidency of the forthcoming Empire Mining and Metallurgical Congress to be held at the British Empire Exhibition on June 3-6, 1924, of which the Prince of Wales is honorary president. The following have accepted invitations to become honorary vice-presidents of the Congress: The Secretary of State for the Colonies; the Secretary of State for India; The Secretary for Mines; the Prime Ministers of Canada, Australia, New Zealand, and Newfoundland; the High Commissioners of the Dominions and British India; and the Lord Mayor of London. The presidents of the seven convening bodies (*v.* NATURE, September 22, p. 453) will act as vice-presidents and will preside over the sections with which they are concerned.

THE issues of the Journal of the Royal Society of Arts for October 5, 12, and 19 contain the three Cantor Lectures by Mr. J. E. Sears on precise length measurements. To those who have not access to the various publications of the National Physical Laboratory, these lectures provide up-to-date information on the methods in use there for maintaining the ultimate standards of length and for accurately comparing the secondary standards in use in industry with the ultimate standards. The instruments used are almost all unique, and the accuracy attained with them one-millionth of an inch. We are glad to note that, as the result of work done by one of the staff of the Laboratory, it is likely that gauges of the accuracy of the Johansson gauges from Sweden will be made on a commercial scale in Great Britain.

ON Thursday and Friday, November 8 and 9, the sixth joint meeting of the Challenger Society and representatives of Marine Biological Stations was held at Cambridge under the chairmanship of Prof. J. Stanley Gardiner. The meeting was attended by more than fifty representatives of various organisations. Papers were read by Messrs. J. Barcroft, G. Bidder, F. F. Blackman, H. G. Carter, H. M. Fox, J. Gray, W. B. Hardy, H. G. Hopkins, T. Moran, J. Piqué, F. A. Potts, J. T. Saunders, and J. M. Wordie. Special attention was paid to the problems of cold storage. These meetings, which were inaugurated and are assisted by the Development Commission, are held periodically at the various marine laboratories and elsewhere.

THE opening meeting of the Illuminating Engineering Society on November 13 was, as usual, devoted to reports of progress and exhibits illustrating developments in lighting. Mr. Gaster, reviewing progress during the vacation, alluded to the appointment of a Committee on Illumination by the Department of Scientific and Industrial Research, and mentioned that the next technical session of the International Illumination Commission is to be held in Geneva in July next year. A conference dealing, among other matters, with industrial lighting, is being arranged by the International Labour Bureau of the League of Nations in Geneva in the same month. Reference was made to the newly-formed Association of Public Lighting Engineers as an illustration of the growing interest in illumination and the need of bringing the aims of the Society before a wider circle of the public.

This point was again emphasised in the report presented by the Committee on Progress in Lamps and Lighting Appliances, which described efforts being made to effect standardisation of lamps and fittings. Amongst other recent steps ten standard types of lamps suitable for automobile headlights, meeting the requirements of practically all British cars, have been evolved. Mr. L. E. Buckell showed some of the very large gas-filled electric lamps consuming 3000-4000 watts and other types with filaments specially designed for projector work. A new feature was the process for spraying bulbs with finely divided china clay; this gives a soft light and good diffusion, with an absorption estimated not to exceed 7 per cent. The sprayed surface is said to have good wearing properties, and it is believed that these lamps will prove useful in cases where they are unavoidably exposed to view in the direct range of vision and yet it is desirable to avoid glare. Miss Beatrice Irwin gave a demonstration of the colour filter system associated with her name, a variety of lighting units consisting of cylinders of hand-painted parchment paper in pleasing combinations of colours being shown.

LEAFLET R. 58 received from Messrs. Newton and Wright, Ltd., 471-3 Hornsey Road, N.19, describes the "Harley" unit for dental radiology. The chief feature of the apparatus is in the movements of the X-ray tube, which is a very important feature in practice. Flexibility is here combined usefully with rigidity, and arrangements are made which allow of stereoscopic radiographs being taken. The high-tension transformer is oil-immersed, and when in action one pole is earthed; a separate transformer with the necessary adjustments for the control of the filament current of the Coolidge tube is supplied. In order to vary the penetration of the X-rays, four alternative voltages may be applied to the tube terminals. This appears to be an ample margin for the requirements of dental radiology.

MESSRS. C. F. CASELLA AND CO., LTD., 49 and 50 Parliament Street, London, S.W.1, have issued a new catalogue, No. 523, which contains particulars and illustrations of a very wide range of surveying and drawing instruments and appliances. Detailed specifications are given of the more important instruments manufactured by the firm. In the design of several of these, many improvements are embodied, which either give some additional facility to the user or increase the accuracy or length of life of the instrument. A notable addition to the list is the new double-reading micrometer theodolite, which has been designed for geodetic and exploration purposes where accuracy of the highest order is desired. In this instrument the diametrical points of the circle are brought together in one field by an optical arrangement. It is therefore possible to set the telescope on the object, take the readings of the bubbles and all four readings of the circle without moving from the front of the instrument. The length of time spent in taking a set of readings is thus considerably reduced. This improvement is accompanied by a reduction in the number of parts employed, and the possibility of the instrument being put out of adjustment is thereby diminished.

Our Astronomical Column.

REINMUTH'S COMET, 1923B.—The following two observations, both made at Königstuhl, are now to hand, the positions being referred to 1923·0:

	G.M.T.	R.A.	N. Decl.
Oct.	$31^d\ 9^h\ 22{\cdot}1^m$	$1^h\ 15^m\ 11{\cdot}36^s$	22° 26′ 36·0″
Nov.	5 8 15·1	1 17 50·90	19 47 23·2

Mr. Waterfield states, as the result of an unsuccessful visual search, that the object is certainly fainter than the 11th magnitude. This faintness is probably the reason of the delay in obtaining a third observation.

THE NOVEMBER LEONIDS.—Mr. W. F. Denning writes: "Very stormy, unsettled weather prevailed during the most of the period when the return of the November meteors was expected, and it was not possible to watch for the shower on several consecutive nights. Mr. I. P. M. Prentice, of Stowmarket, endeavoured to obtain an early observation of the shower on November 10. For that purpose he carried out a long watch of the heavens commencing at 5.55 G.M.T. and ending at 17.55 G.M.T. He recorded 82 meteors though the sky was partly cloudy at times. Six of the meteors seen were Leonids with a radiant point apparently at 145°+22°. If this position for the radiant is confirmed it will indicate that the Leonid radiant, similarly to that of the great Perseid shower of August, is a movable position which advances about 1° per day. On November 11, Mr. Prentice saw 35 meteors, but the sky became cloudy before 14.50 G.M.T. and watching had to be discontinued. At 12.38 G.M.T. he saw a bright fireball directed from a shower of Taurids. It would be interesting to get another observation of this if other observers happened to be looking for Leonids on the night of November 11 at about 12.38 G.M.T."

THE EXTRAFOCAL METHOD OF STUDYING MAGNITUDES.—The advantages of this method are the practical equalisation of the size of disc for different magnitudes and elimination of the effect of peculiarities of images arising from defects in the objective. The quantity measured is simply the density of the image. Mr. Edward S. King (Proc. Nat. Acad. Sciences, U.S.A., Oct. 1923) communicates the results for 100 bright stars from Harvard observations. A yellow screen and isochromatic plates were used, thus giving photovisual magnitudes. The mean excess of the resulting magnitudes over the photometric ones is as follows: B −0·02, A0 0·00, F −0·10, G −0·15, K −0·16, M −0·20. The following colour-indices were deduced: B0 −0·23, A0 −0·02, F0 +0·25, G0 +0·88, K0 +1·28, M +1·87. These are independent of visual observations.

A rediscussion of the observations of Nova Aquilæ, 1918, when near its maximum brilliance, gives colour-index −0·19, instead of −0·35, published earlier. Mr. King also measured the colour-indices of the planets by the same method. The values are: Venus +0·91, Mars +1·45, Jupiter +0·96, Saturn (without rings) +1·22, Uranus 0·74. These accord well with the ruddy colour of Mars and the "sea-green" of Uranus.

The paper also contains new formulæ for the effect of phase-angle on the magnitudes.

Research Items.

Mycenæan Elements in the North Ægean.—Mr. Stanley Casson has contributed to the November number of *Man* an interesting analysis of the traces of intrusive Mycenæan culture in Macedonia and Thrace. Mycenæan pottery is derived from nine mounds in the Thermaic Gulf, mostly in the neighbourhood of Salonika, and all but three on the seashore. All this Mycenæan ware belongs, with one exception, to the close of the third Late Minoan period. Mr. Casson's conclusion is that probably Mycenæan imports were purely local and were derived by trade along the sea route from the south to the Thermaic Gulf. He figures two rapiers from Grevena on the upper waters of the Haliacmon and one from Karaglari in the Central Bulgarian Plain which belong to the type of Mycenæan rapier common in the last two Minoan periods. The former appears to have passed up the Vardar Valley or by way of Thessaly; the latter along the Struma. East of the Struma no traces of Mycenæan culture are recorded along the European shore, and Mycenæan traders appear to have had no port of call between Salonika and Troy.

Climate and the Nasal Index.—At the International Medical Congress held in London in 1913, Prof. Arthur Thomson read a preliminary communication on "The Correlation of Isotherms with Variations in the Nasal Index," in which it was suggested as a result of a survey of the nasal indices of the inhabitants of America that the greatest nose-width was to be found near the "heat-equator," and that a narrowing was to be found in passing north and south to Baffin's Bay and Tierra del Fuego. A joint paper by Prof. Thomson and Mr. L. H. Dudley Buxton which appears in vol. liii., pt. i. of the Journal of the Royal Anthropological Institute, gives the results of an extended investigation on these lines, from which it would appear that in fact a platyrrhine nasal index is associated with a hot moist climate and a leptorrhine nasal index with a cold dry climate; the intermediate conditions being associated with hot dry and cold moist climates. Both on the living (males) and on crania there is a positive correlation between nasal index and temperature. The same applies to nasal index and relative humidity in the living, but in crania the correlation is small. The result of the application of this line of investigation to prehistoric skulls is interesting. The platyrrhine character of the Grimaldi skulls would assign them to a warm Mousterian period; but the skull from La Chapelle aux Saints, being platyrrhine, should belong to a warm period, whereas it is usually assigned to a cold Mousterian period.

Freudian Psychology and Evolution Theory.—In the Transactions of the Croydon Natural History Society (vol. ix. pt. 3) there is an interesting article by Mr. C. C. Fagg on the "Significance of the Freudian Psychology for the Evolution Theory." The article consists of three parts. In the first the author outlines the discoveries of Freud, in the second he sketches the salient features of the evolution theory, and in the third he attempts to interpret the second in the light of the first. The paper is interesting as an indication of a scientific attitude of mind towards the Freudian theory. That theory has suffered almost equally from the uncritical assimilation of all its tenets by enthusiastic supporters and from the still more uncritical attacks of those who found its doctrines unpalatable. Mr. Fagg relates certain aspects of it to phenomena well known in the biological sciences. He interprets the stalk of the fixed infusorian as of the nature of a neurotic symptom; some amœboid forms reacted to fear, as in the case of the foraminifera, by putting on a coat of armour made of carbonate of lime or silica, a compromise formation which put a limit to their evolutionary possibilities; only those amœboid forms which retained their mobility and plasticity in the face of danger were able to bridge the gulf to metazoic life. He holds that there are many instances from palæontology to show how, in reacting to fear of environmental dangers, races have sold their souls, so to speak, for some measure of security. He believes that a consideration of some of the findings of Freud would do much to help in the aggravated question of the inheritance of acquired characters. He hopes that by an extension of our knowledge along the lines indicated by psycho-analysis we may some day be able to make a world fit for children to live in, a family and social environment in which super-babies may develop into super-men.

Cattle Feeding.—The idea which appears to have suggested the investigation recorded in "Under-Nutrition in Steers," by F. G. Benedict and E. G. Ritzman (Carnegie Institution of Washington), is that it might be economically advantageous to underfeed cattle during the winter, when feeding stuffs are scarce and dear, if it could be demonstrated that a prolonged period of semi-starvation did not inflict on the animals any permanent disturbance of their internal economy such as would hinder their fattening in the succeeding summer. For the purpose of the investigation 14 steers in all were intensively studied, 12 of them during the year November 1918 to November 1919, and 2 during the succeeding year. For the first fortnight the ration aimed at bare maintenance, for the next six months at approximately half maintenance, after which a full fattening ration was given. It was found that although during the six months on half maintenance the animals lost approximately 25 per cent. of their original live weight, they soon regained this when given a full ration, after which they fattened normally, and, when slaughtered, produced saleable beef. Thus the absence of permanent ill effects of prolonged and severe under-nutrition is clearly demonstrated, but it is unfortunate that the authors were prevented from considering the economic results of their investigation. In the absence of any economic discussion it cannot fail to strike the British reader that the investigation loses much of its importance. Under-nutrition of store cattle during the winter is a common phenomenon in the pastoral districts of the west of England, and when practised on young animals is supposed to be responsible for many of the shortcomings of stores which are transported to the Midlands and the Eastern Counties for subsequent fattening. The publication contains, however, clear descriptions of many very ingenious instruments used in the determination of the digestibility of the feeding stuffs and in the measurement of gaseous metabolism. Many British experimenters would profit by studying the discussion of the accuracy of live weight measurements on which they are apt to place implicit confidence.

Plant Propagation.—Mr. C. T. Musgrave has an interesting note in the Journal of the Royal Horticultural Society, volume 48, parts 2 and 3, issued September 1923, under the title "Methods of Propagation in an Amateur's Garden," which again directs attention to the numerous problems that immediately arise when the empirical data, alone available in this subject, are passed under review. Mr. Musgrave distinguishes between hardwood cuttings of woody perennials, which have ceased growth for

the year, and soft cuttings, among which he distinguishes again between truly soft herbaceous plants, such as the geranium, and the "firmwood" cutting of a shrub such as Escallonia. For firmwood cuttings he agrees with the practice of using a side shoot, torn from the parent stem with a downward pull so that a little "heel" of the main stem is left attached to it. Such "heeled" cuttings are described as almost invariably easy to strike. Fuchsia, on the other hand, strikes better if a piece of stem is cut off just below a node, rather than from a side shoot broken off with a "heel"; clematis again, for some puzzling reason, always roots best if cut about an inch below a node. The author points out that the layering method so frequently adopted with carnations is also very successful with rhododendrons, hardy azaleas, and other hardy shrubs.

Assimilating Tissue in the Plant.—As first part of vol. iv. of the Handbuch der Pflangenanatomie, edited by K. Linsbauer (Berlin: Gebrüder Borntraeger, 1923), there has appeared a review of the assimilating tissues by Fritz Jürgen Meyer. A full bibliography and index appears with the review. The various forms of assimilating tissue are fully described, palisade and spongy tissue, arm palisade, assimilating epidermis and bundle-sheath, etc., and a résumé given of the various views as to the development from special assimilating tissues. The conclusion seems to be that we have not yet escaped from a somewhat barren controversy as to the relative importance of alternative teleological explanations based upon its assumed functional activity. The main protagonists have been Stahl and Haberlandt. Stahl argued that the palisade system was the ideal system for strong light, the spongy for weak light, hence the relative proportions of these tissues in sun and shade leaves. That light exerts an important influence is supported by the recent experiments of Liese, which show the walls of the palisade cells adopting a different angle when developing in a radiation that comes in different directions. Haberlandt, on the other hand, developed as explanatory principles two adaptational requirements—(1) an increase of cell surface, his main clue to the structure of palisade and arm-palisade tissue; (2) an increase of length in the direction along which assimilates move in the cell, an important guide to the interpretation of spongy parenchyma. Other authors, notably Areschoug and Rywosch, have argued stoutly for the importance of transpiration and the moisture conditions of the leaf, finding various reasons why different types of tissue are best suited to certain moisture conditions. All these views are usefully and critically reviewed in this monograph.

Indian Agricultural Statistics.—The agricultural statistics of India for the year 1920–21 have been published in two volumes by the Department of Statistics, Calcutta; the first volume deals with British India and the second with certain Indian states. Among a mass of valuable returns dealing with acreage cultivated, areas under irrigation, extent of different crops and live-stocks, and harvest prices, it may be noted that the total area sown with crops in British India in 1920–21 was 5 per cent. less than the previous year, and represented 34 per cent. of the total land area. Owing to the fact that some areas are sown more than once in the year, the gross sown area really amounts to rather more than this figure. In the native states the sown area was about 40 per cent. of the total land area. Food crops accounted for 82 and 77 per cent. respectively of these two totals. The irrigated area in British India remained practically constant, while in the native states there was a slight increase. The area under cotton showed a decrease of 9 per cent., and the area under oil seeds, 2 per cent. The rainfall was above normal in Bengal and Assam and much of Burma, defective in the United Provinces, Rajputana, and Bombay, and especially so in the Punjab, Sind, and Central India, but excessive in Madras.

Australian Notonectidæ.—The Australian waterbugs of the family Notonectidæ form the subject of a contribution by Mr. Herbert M. Hale to the Records of the South Australian Museum, vol. ii. No. 3, June 1923. The predominant genus is Anisops, which has eight species; nothing previously appears to have been known concerning its life-history. Mr. Hale has been able to fill this gap to some extent in describing the biology and metamorphoses of the commonest species, *A. hyperion*, which occurs in both running and stagnant water. It was reared upon mosquito larvæ and pupæ, which were eagerly devoured, an average of 200 being consumed by each isolated nymph in less than four weeks. Among other genera, Notonecta and Plea are each represented by a single species and there is but one member of the family Corixidæ—*Porocorixa hirtifrons*.

Recent Shells from Java.—This first instalment of what promises to be an important catalogue of the "Recent Shells from Java" contains an enumeration of the Gastropoda by Dr. C. H. Oostingh. The work, written in English, is founded on a collection, chiefly of marine shells from Java, which is kept in the Geological Museum of the Agricultural High School at Wageningen (Holland), and of this by far the greater part was made by Prof. J. van Baren. An exact knowledge of the recent molluscan fauna being of much importance for the study of the Upper Tertiary fauna of Java, the author has approached the subject in some detail. That is to say, a copious synonymy, and notes of its distribution in the western Pacific generally, with geological occurrences where known, are given with each species, while there is a very good phototype plate of some of the forms.

The Glaciation of North-eastern Ireland.—Major A. R. Dwerryhouse contributes a remarkable paper on this subject to the Quarterly Journal of the Geological Society of London, vol. 79, p. 352 (Sept. 1923). The area covered is a wide one, from Torr Head to Slieve Gallion, thence across the wild moorland of central Tyrone; then away to the east coast again across Lough Neagh, and down to the narrow inlet of Carlingford Lough. The author recognises this inlet as a true fjord excavated by glacier-ice during the later phase, when the ice-flow from the north-west dominated that from the Irish Sea. Good use is made of the presence of pebbles from Ailsa Craig in inland districts, and the course of the Scottish ice (Firth of Clyde glacier) across the country during the earlier phase is strikingly shown upon the maps (p. 419, etc.). The careful work of years is embodied in this paper of seventy pages, and we can only regret that space has not allowed of the description of the picturesque scenic features added by drift-mounds and eskers to the floors of valleys or the barren surface of the moors. Special attention is paid to the gravel-terraces deposited in ice-dammed lakes, and to the dry gaps as records of overflow-channels throughout the district. It is pointed out that the recognition of the true nature of these channels in north-eastern Ireland dates from the work of the Geological Survey in 1904. Here, as elsewhere in Ireland, Mr. G. W. Lamplugh laid the foundations of a very marked advance.

THE WATER SUPPLY OF NYASALAND.—There exist in Nyasaland large tracts of fertile land which are deficient in water supply. If this defect could be remedied these areas would be available for settlement by natives or Europeans. In Water Supply Paper No. 1, issued as a supplement to the *Nyasaland Government Gazette* of June 30, Dr. F. Dixey considers the possibilities offered by underground water. The rainfall of Nyasaland varies from 30 to 80 inches a year, but the long dry season which follows the rainy season leads to great evaporation of surface water. In consequence, in any improvement of the supply, resource must be had chiefly to underground supplies. The granites, gneisses, and schists of the country are not too favourable in this respect, but in the Shire valley there are extensive alluvial deposits and, west of the Shire river, sandstone and shales overlie the crystalline rocks. It is in the last-named rocks that the problem is most difficult of solution. Dr. Dixey compares the conditions with those obtaining in Southern Rhodesia, where at shallow depths an appreciable supply of water is obtained from percolation in joints and fissures. He believes also that a certain supply may be obtained from shallow depressions, known as "pans" or "vleys," which indicate a considerable depth of weathered rock. In areas unfavourable for wells, the construction of impermeable collecting slopes and storage tanks is recommended. On such a slope a rainfall of 20 inches should yield 450,000 gallons per acre.

VARIABILITY OF TROPICAL CLIMATES.—A series of articles have appeared in the issues of the *Meteorological Magazine* for July, August, and September by Dr. Stephen S. Visher (Chicago) on the above subject. The opinion is held that the general emphasis upon uniformity in the tropics is misleading, and attention is directed to the variations of temperature and wind, while rainfall in lower latitudes is shown to be more variable on the average than the rainfall of higher latitudes. For seasonal range of temperature, amongst many other places, Hong Kong in latitude 22° N. with a range of 20° F. is compared with Glasgow in latitude 56° N. with a range of 12° F. It is pointed out that the latitude of Switzerland receives much more heat from the sun on June 21 than the equator, for the sun at that time is about equally vertical in the two places, while in Switzerland the days are about 4 hours longer. Cold snaps are shown to occur commonly in the tropics from various causes. With respect to variability of rainfall, comparison is made between the wettest and driest years in tropical regions and those in higher latitudes. The wettest years out of the tropics seldom exceed more than double the rain of the driest years, while in the tropics the variation of range is much greater. An important factor in these comparisons is the length of the period dealt with; this is recognised by the author. The total rainfall in wettest years is very much larger in tropical regions than in higher latitudes. The erratic nature of cyclonic storms in different parts of the world is referred to, and for frequency and violence the extremes are said to be greatest in low latitudes.

ATOMIC WEIGHT OF BORON.—We have received a copy of vol. 59, No. 2 of the Proceedings of the American Academy of Arts and Sciences, which contains a paper by Baxter and Scott on a revision of the atomic weight of boron. Taking silver as 107·88, these workers find that boron is 10·82 from analyses of the trichloride and tribromide of boron. Improved methods for the fractional distillation in vacuum of boron halides are also described.

SYNTHESIS OF LECITHIN.—Dr. A. Grün and R. Limpächer reported to the congress of German chemists, recently held at Jena, that older preparations, which had been taken for artificial lecithin, were nothing but choline salts of glycero-phosphoric acid. True lecithin is obtained by the action of diglycerides upon phosphoric anhydride, and subsequent action of choline bicarbonate. The purified product has all the physical and chemical properties of the lecithin prepared from seeds, egg-yolk, and the substance of nerves and brain. Optically active lecithins are also obtainable in this way; the kephalines can be prepared from diglyceride, phosphoric anhydride, and colamine.

NITROGEN CONTENT OF WHEAT GRAIN.—The importance of a high nitrogen content of the wheat grain has led Olson (*Journ. Agric. Res.* xxiv., 1923) to attempt to ascertain whether this can be varied by alteration in the controllable conditions in the environment of the wheat plant. The nitrogen content seemed to be increased by widening the distance between the drills when no irrigation was applied, but under irrigation in another district this effect was not obtained. On the other hand, irrigation *per se* exerted no influence in either direction. As maturity approached, the nitrogen in the plant moved towards the grain, though the actual percentage in the latter decreased, apparently owing to the more rapid infilling of carbohydrates. It would appear that larger quantities of water are required to move the nitrogenous matter than the non-nitrogenous into the grains, and accordingly an ample supply of water should prove beneficial to high rather than to low nitrogen content, which rather contradicts the findings with regard to irrigation. Phosphorus and nitrogen were found to enter the grain simultaneously, thus corroborating the results of other investigators.

LEAD AND PLANTS.—The application of radioactive isotopes as indicators, mainly by Hevesy and Paneth, has proved to be a powerful method of attacking many physico-chemical problems that do not readily lend themselves to direct methods. A further interesting application of this method is given in the current issue of the *Biochemical Journal* (vol. xvii. pp. 439-445, 1923) by Prof. Hevesy (Copenhagen), who has investigated the "Absorption and Translocation of Lead by Plants." Specimens of *Vicia Faba* (horse-bean) were immersed in lead nitrate solutions of different concentrations containing thorium B (isotope of lead) as an indicator, and after ignition of the various parts of the plant their lead content could be found by radioactive measurement of the ash. Quantitative results have been obtained using solutions varying in concentration as much as from 10^{-6} N. to 10^{-1} N. In 24 hours the root of the plant absorbed in the former case 60 per cent. of the lead contained in 200 c.c. of the solution, whereas in the latter case only 0·3 per cent. was absorbed. The amount of lead passing into the stem and leaves is less than 1/10 per cent., and does not vary greatly with the solution concentration, indicating that most of the assimilated lead is bound to the root, and experiments on displacement show that it is associated in the form of a dissociable but not readily soluble salt, and not in combination with carbon. Whereas a 10^{-1} N. solution of a lead salt produces toxic effects on the plant even after 24 hours, more dilute solutions do not. Experiments on the kinetic displacement of assimilated ions by other ions are described in connexion with the phenomenon of "antagonism," according to which certain ions have the capacity of inhibiting the toxicity produced by others.

Cohesion and Molecular Forces.

IN opening a joint discussion on cohesion and molecular forces between Sections A, B, and G of the British Association at its recent meeting at Liverpool, Sir William Bragg emphasised the change of point of view which the analysis of crystal structure by X-rays has brought about. The older view, in which atoms and molecules were pictured as centres of force exerted in all directions, and governed by some power law of the distance between them, has had some measure of success in explaining the principal features of surface tension and some of the departures from perfection in a gas. But in a solid, except possibly in the case of polar compounds, no satisfactory results have accrued. On the newer view we consider, not the aggregate, but the individual, atom or molecule.

It appears to be necessary to say that the very strong forces between atom and atom, molecule and molecule, are limited in their effective range of action to distances much smaller than we have hitherto supposed. Small, it may even be, compared to the distances between the centres of atoms as they lie side by side in a crystal. A crystal conforms so exactly to rules respecting its angular dimensions that it seems impossible to imagine its form to be merely the result of an average of tendencies. The forces of adjustment cannot, therefore, be thought of as a force between two points each representing one of the molecules. On the contrary, it is nearer the truth to think that the adjustment is made so as to bring together certain points on one molecule and certain points on the other. In considering, therefore, the binding of the individual molecules of a solid, the analogy of the electrostatic attraction of two charged spheres is imperfect, and should be replaced by that of two members of a girder structure adjusted until the rivets can be dropped into the holes brought into true alignment. This is seen well in the recent work by Muller and Shearer, and by Piper and Grindley on the structure of the organic fatty acids and their salts. There is no doubt that the ultimate flakes of the crystals of these fatty acids are the monomolecular films investigated by Langmuir and by Adam, and it would appear that in passing from one acid to a homologue of greater molecular weight, each addition in thickness of the ultimate flake is made in complete independence of the previous length, as if the only thing that mattered was the nature of the attachment of one carbon atom to the next. There is no influence of the ends upon the atoms in the middle. Again, we have the forces different at different parts of the atomic surface, as in the case of bismuth and its homologues, in which the atom is attached to three neighbours on one side by bonds differing from those which attach it to its three neighbours on the other.

With regard to the nature of these binding forces three types may be recognised. First, there is the effect set up by the sharing of a pair of electrons by two contiguous atoms, leading to strong and directed attachment. Next, there are actions of a different and generally weaker type manifested in the binding of molecule to molecule in a crystal. We may be sure that this type plays an important part in metals and alloys. Lastly, there are the pure electrostatical central actions. In the case of the polar crystal Born and Landé have made some progress in calculating the effect of this.

One well-known fact in crystal growth is that the faces have different rates of growth, indicating that there may be great differences in the ease with which molecules slip into their places. Into this the element of time may enter, because a molecule may come nearly into its right place and be held there sufficiently long to get settled in by thermal agitation or otherwise. We may suppose that the formation of the crystal begins correctly enough, but that errors of adjustment creep in until the surface becomes somewhat disordered, and the growth ceases because fresh molecules cannot find their proper places to slip into. Without a more detailed knowledge of the active forces localised at various points of atoms and molecules we cannot build up a complete theory of cohesion.

Dr. Rosenhain, who followed, dealt with the simple monatomic bodies—the metals—in which the development of strength and ductility is so pronounced. In his opinion it has now become possible to sketch certain principles from which a general theory of the nature of alloys may arise. The first is that the atoms of two metals in solid solution are built on a simple space lattice, the atoms of the solute metal taking the places of a corresponding number of atoms of the solvent metal, the lattice remaining essentially unaltered. The presence of a "stranger" atom produces a certain amount of distortion which is responsible for the changes in the hardness, strength, melting point, and other properties of the metal. The second principle is that the inter-atomic distance through which interatomic cohesion is appreciable is strictly limited. When increased by any means—thermal expansion, mechanical stress, or "stranger" atoms—a limit is soon reached when the lattice breaks down suddenly with the formation of another phase. On heating, such a change is simply melting; on straining, it is the breakdown of elastic behaviour; and on alloying, we have the limit of solid solubility resulting in the formation of crystals of a new type. In many metals cohesion phenomena are complicated by the occurrence of intra-crystalline slip, which results in plastic deformation under stress by the process of slip along certain planes within the crystal. At the surface of slip there must be a rapid exchange of partners without loss of continuity of bonding. It is interesting that the phenomenon is confined to metals crystallising in the two most symmetrical systems, in which, presumably, the distribution of atoms is sufficiently uniform to permit the passing on of bonds to take place.

The mechanism of ductility by means of slip is intimately connected with diffusion in solid crystals. In Dr. Rosenhain's opinion the process of diffusion of one metal into another, the structure of which is already that of closely packed lattices, may be due to movement or slip of atoms in rows, the requisite stress, which at high temperatures need not be great, being provided by the lattice distortion arising from a concentration of "stranger" atoms in a solid solution of non-uniform concentration. On this view ductile metals should allow diffusion far more readily than brittle. It is well known that brittle metals, like antimony and bismuth, show no appreciable diffusion until quite near the melting point. Moreover, it is known that nickel and copper—two very similar atoms—exhibit extremely slow diffusion as compared with zinc and copper. This fits with the above view and is at the same time not to be expected on the view that metallic diffusion is a kinetic phenomenon similar to that of liquids and gases. On the same principles, a crude picture of the constitution of an amorphous solid fitting the facts in a general way may also be formed.

With regard to the method of binding of two crystal lattice systems growing towards one another,

one is struck by the fact that the junction of crystal to crystal is not a region of weakness, but is in fact the strongest part of a crystal aggregate. Metals, when forcibly broken in the cold, normally break through the crystals and not along the junctions. There are a large number of experimental facts supporting the view that the gap between two adjacent lattices is bridged by a region of irregularly arranged atoms constituting a layer of amorphous material of excessive strength.

Finally, while in solid solutions we find that the interatomic distances, though varying a few per cent., are roughly constant, in well-defined intermetallic compounds the interatomic distances are sometimes greatly reduced. Thus, in aluminium, the distance is of the order of 4·3 Å.U., but in the compound $CuAl_2$, aluminium atoms are found with a centre distance of only 2·42 Å.U. In this case, therefore, the nature of the interatomic binding must be quite different, and this probably constitutes the real difference between a compound and a solid solution.

Dr. A. A. Griffith, who followed, pointed out that while at first sight the correlation of data on the breaking strengths of materials with the magnitude of cohesive forces derived by physical method should be comparatively simple, this is far from being the case. One reason for this is that the majority of structural metals are ductile, so that under ordinary stress systems, which almost invariably comprise shearing stresses, the primary failure of the specimen does not involve atomic separation at all but is a failure in shear. Now the mode of collapse of a space-lattice in shear is a subject which has been studied very little by physicists, so that practically no information from the point of view of molecular cohesion is available to engineers.

In the case of certain materials, for example, glass, stone, and hard steel, which exhibit brittle fractures running perpendicular to the direction of the greatest tensile stress, some progress in the subject has been made. Calculations show that in such cases the observed tensile strength is only a small fraction of the calculated molecular tenacity. This discrepancy may be avoided if one assumes the existence of minute cracks in the material fracture being due to the very severe concentration of stress at the corners of the cracks. A formula may be developed which gives results of the right order of magnitude if the radius of the corners of the cracks is taken as two or three molecular spacings. There is another type of fracture obtained with brittle materials, namely, cracks running obliquely to the principal stresses, the best known case being the crushing fracture obtained by simple compression. This may be treated in a somewhat similar manner by the assumption of a large number of minute cracks oriented at random in the material.

With regard to the breakdown of ductile metals, Dr. Griffith and Mr. Lockspeiser have worked out a theory of plastic strain in which the conclusion is reached that plastic strain is simply the external manifestation of phase changes occurring within the material. This view in itself is not new, but the novelty arises from the fact that deductions are made regarding the number and nature of the distinct phases concerned in the action. The question arises whether it is likely on physical grounds that phase changes can occur as a result of the application of a shear stress; given that this is so, the evidence is more in favour of a resultant change in relative orientation of the atoms than of their configuration.

Prof. Lindemann considered that the assumption made by previous speakers that atoms or molecules are either bonded together, or not bonded, is premature, and cited the fact that fairly definite evidence for intramolecular attraction without definite bonds is to be found in the Sutherland correction to the temperature coefficient of the viscosity of gases, derived by assuming mutual attraction of molecules and verified experimentally.

Prof. R. W. Wood mentioned an interesting experiment requiring explanation. A crystal of rock salt placed in hot water can be immediately bent by the fingers, and remains deformed when removed from the water. The range of temperature over which this has been observed is small and the phenomenon does not occur in the case of immersion in hot oil.

To sum up, the discussion brought out clearly the fact that we are still only at the beginning of a complete explanation of the general phenomena, and there was point in the somewhat facetious remark of Sir Oliver Lodge that it was an extraordinary fact that, after all these years, three important sections of the British Association should be gathered together to discuss why, when one end of a stick is raised from a table, the rest of it also comes up.

Paris Meeting of the International Council for the Exploration of the Sea.

THE sixteenth annual meeting of the International Council for the Exploration of the Sea was held in Paris, on the invitation of the French Government, on October 1–5. By the courtesy of the Administrative Council, accommodation was provided for the Council in the Institut Océanographique, founded by the late Prince Albert of Monaco. The following countries, members of the Council, were represented: Belgium, Denmark, Esthonia (for the first time), Finland, France, Great Britain, Holland, Norway, Portugal and Sweden. Representatives of the Irish Free State attended as visitors.

The usual committees and sections for hydrography, plankton, statistics, herring, plaice, cod and haddock, limnology, the Baltic Sea and the Atlantic Slope were assembled, and a new committee, named the North Atlantic Committee, was formed.

It is important to observe that all committees and sections are now instructed to formulate precise programmes of work, allotting to each country concerned a definite part in the programme, which it undertakes to perform. Each country is called upon afterwards to report to the Council on the work it has carried out in accordance with these undertakings, and the effect of these reports is embodied in a general progress report submitted to the Council at each meeting. The tendency to present excellent but unrealisable recommendations is thus discouraged.

For the most part the committees reaffirmed their existing programmes in respect of which generally satisfactory progress was reported. It will be observed that there are three committees for the study of particular fishes. The Plaice Committee, the recommendations of which for the protection of the plaice fisheries were adopted by the Council in 1922, and are now under the consideration of the participating Governments, is chiefly engaged in watching developments and checking its own conclusions.

The intensive investigations of the plaice having thus come to a pause, the study of the herring, cod and haddock is being vigorously prosecuted, in accordance with comprehensive practical programmes adopted in 1921, and afterwards modified in the light of experience. Unfortunately, owing to the difficulties of the time, many of the countries concerned are

inadequately equipped for work at sea, and the bulk of the sea work falls on England and Scotland. It is particularly regrettable that Norway, to which, in the person of Dr. Einar Lea, is entrusted the leadership of the herring investigations, has not yet been able again to equip a ship for deep-sea research. The herring investigations at their present stage involve, to a considerable extent, the application to the investigation of North Sea herrings of the methods employed by Hjort and Lea in their investigations of the Norwegian herrings. With a view to the standardisation of these methods, English and Scottish naturalists are studying under Hjort and Lea at Christiania.

The Cod and Haddock Committee is under the convenership of Dr. E. S. Russell; but the work of direction is divided between England and Scotland, the latter being responsible, through Dr. Bowman, for dealing with haddock material and the former with cod.

The proposal to form a North Atlantic Committee was approved after a lengthy debate in a special committee of the whole Council. On one hand it was felt that the committees were already dangerously numerous, that the fishes which would come under examination by the North Atlantic Committee were mainly those actually being investigated by other committees, and that a further extension of the principle of geographical division of work already accepted in the formation of the Committee of the Atlantic Slope and the Baltic Committee created the risk of redundancy unless it could be shown that the area to be studied was, in respect of some at least of its features, self-contained, and presented phenomena peculiar to itself. It was more particularly on the last-named ground that the Danish Commission in a memorandum submitted to the Council supported their proposal, which had for its principal object the study of the fisheries of Iceland and Faroe. They pointed out that the Icelandic fisheries in particular, and the physical conditions governing those fisheries, presented peculiarities which merited individual study. They summarised their argument in the following terms: "In regard to fishery biology as well as hydrography the various parts of the Icelandic area are extremely dissimilar. There is in fact a greater difference in this respect between South and East Iceland than between South Iceland and the Faroes, or, indeed, between South Iceland and Ireland."

The Council eventually resolved to form a North Atlantic Committee for research north of the latitude of Rockall, and, while instructing the Committee to commence work in the area suggested in the Danish Commission's memorandum, urged it to keep in mind the importance of extending its area of observations particularly to the eastern and northern parts of the Norwegian Sea. The Committee was further instructed to arrange its programme in consultation with the other committees concerned. The programme adopted, in accordance with this instruction, provides for the hydrographical and biological investigation of the region, with special reference to cod, haddock, halibut, plaice and herring. The leadership of the work was entrusted to Dr. Johs. Schmidt. The greater part of the sea work will be carried out by means of the *Dana*, but France will make provision for observations by means of cruisers stationed at Iceland, and Scotland will conduct hydrographical-biological cruises from the west of Scotland to the Faroes. England will assist with fishery statistics and measurements.

An interesting discussion arose in connexion with the work of the Statistical Committee, of which Prof. D'Arcy Thompson is permanent chairman. The British delegates were instructed to endeavour to secure the general adoption of more effective and, in particular, more uniform statistical methods, such as are in use in Great Britain. Owing to the lack of uniformity of method, it is at present most difficult to present in the Bulletin statistics which afford a true indication of the actual condition of the fisheries in a given region or part of a region, and of the variations of the stock from year to year. For example, different countries while using the same regional nomenclature have different conceptions of the limits of the regions, and the majority of them are not able to give any accurate idea of the precise locality fished or of the amount of fish of any given species—or of fish of all kinds—taken per unit of time; *e.g.*, the quantity of fish taken in a given area in 100 hours' fishing. Statistics which do not present a picture of the distribution of the stock in time and space are of little value to the scientific worker, and it is for scientific rather than for commercial purposes that the International Council should collect and publish statistics. It was readily agreed by the Statistical Committee that uniformity must be secured in the matter of the designation of statistical regions and areas; but it was impossible in the time at the disposal of the Committee to arrive at unanimity as to the limits by which the regions should be defined. This question was accordingly referred to a special sub-committee which was requested to report to the committee before the next meeting of the Council. The question of getting detailed statistics of locality of capture, *i.e.* fishing ground, and of the relation of fishing power to catch of fish, proved to be one of ways and means, and the reply of most countries was that they had not the staff for the collection of such statistics on the scale adopted in Great Britain. Eventually it was agreed that each country should endeavour to collect statistics from some of its vessels according to the methods employed in England, and an undertaking was given on behalf of the English Department, being the best equipped for the purpose, that the Department would for the present work up the data if sent to them.

The work of the Committee of the Atlantic Slope continues to be under the leadership of Dr. Edouard le Danois. The English Department is not yet in a position to take part in the sea work, but it is hoped that the Marine Biological Association will continue the assistance which it has given in the past.

A memorandum was submitted to the Council by Prof. Otto Pettersson and Commodore C. F. Drechsel advocating an international expedition to study the system of currents of the great oceans, with reference especially, to quote from the memorandum, to the following questions:

"(1) Whether the changes we observe in the fish life of our seas correspond with the changes we observe in the current system of the ocean; and

"(2) Whether these changes are of periodic nature."

The authors of the memorandum, which gave rise to a most interesting debate, urged that advantage should be taken of the fact that the late Prince of Monaco's yacht *Hirondelle* was for sale to secure and equip this vessel and to employ it for four years in an investigation of the questions above stated. They invited the Council to support the proposal, which they desired to submit, with the authority of the Council, to the governments of the civilised world, in the hope of securing the co-operation of all these governments in the enterprise. They pointed out that if the proposal secured world-wide support the actual cost to any individual country would be comparatively small. In the debate which took place

upon the memorandum it was freely recognised that the practical difficulties in the way of the realisation of such a scheme would be great. The Council, however, eventually passed a resolution recording its opinion that an increased knowledge of the ocean systems was not merely of scientific interest but of practical importance for the explanation and the forecasting of phenomena affecting life both in the sea and on land, that such an investigation must necessarily be extended over many years, but that it could usefully be initiated by a preliminary reconnaissance on the lines suggested in the memorandum. The Council therefore recommended the proposals to the favourable consideration of the governments and scientific institutions of all countries. In its resolution the Council was careful to point out that such an undertaking as this went far beyond the limits both of its resources and of its mandate, and must be regarded as a distinct and world-wide enterprise. It affirmed, however, its readiness, should the proposal meet with adequate support, to undertake the general direction of the work. It was generally felt that there was no other existing organisation equally competent.

The next meeting of the Council will be held, as usual, in Copenhagen.

Electrometric Methods in Analytical Chemistry.[1]

THIRTY years ago electrometric methods of analysis were too complex for technical purposes, but the importance of "hydrogen ion concentration" re-directed attention to them, with resulting simplification.

When a piece of silver is dipped in a solution, a solution pressure is exerted, silver ions being driven into solution until equilibrium is established between the osmotic pressure of the ions in the solution and the solution pressure of the silver. Hydrogen behaves similarly, as does chlorine. It thus becomes possible to find a suitable electrode for any reaction giving a change in valency.

In the reduction of potassium permanganate the electrolytic potential (ϵ) is given by the formula:

$$\epsilon = \epsilon_0 + \frac{0{\cdot}058}{n} \log \frac{[Mn'']}{[H]^8[MnO_4']}.$$

If the log expression is kept constant there results a normal electrode. In practice such an electrode must be combined with one which changes its potential during the course of the titration. It is possible to titrate silver with halides, sulphides, cyanides, and thiocyanates, and vice versa. An interesting feature is the possibility of the simultaneous titration of halides in admixture, there being successive falls of potential as each is reacted upon by the silver solution. In the presence of protective colloids there is of course no apparent precipitation. It is interesting to note that this does not interfere with the titration.

Protective colloids stop crystal growth and consequently increase somewhat the solubility of the precipitate. This solubility is usually so low that an increase of even 100 per cent. does not lead to appreciable errors. It thus becomes possible to estimate directly small amounts of metal in, say, blood serum. Certain organic substances, such as silver salvarsan, contain silver in such a form that it is not acted upon by chlorides. Use is made of sulphides, the diameters of the ions of which are such that monovalent cations of the dimensions of silver ions are unable to resist their influence. Ionic dimensions play an important part in determining the insolubility of certain precipitates.

Titrating zinc in acid solution with potassium ferrocyanide, curves not of the usual bi-logarithmic type are obtained. The abnormality is due to small amounts of ferric iron. On filtering through aluminium powder, reduction to ferrous iron takes place and normal curves are obtained.

For nickel and cobalt in admixture electrometric titration with potassium cyanide is the best. The complex ions $''Ni(CN)_4$ and $''Co(OH)(CN)_5$ are formed. The curves obtained yield no evidence of the formation of intermediate complexes.

For oxidation and reduction titrations a platinised electrode is most satisfactory. Titanium may be estimated very accurately in the presence of iron after filtration through a cadmium powder filter in an atmosphere of carbon dioxide and subsequent titration with potassium dichromate. If a blank electrode is employed it is liable to become passive at the end of the titration, producing a sudden drop of potential instead of a rise.

With regard to dye-stuffs there is little to add to the excellent methods of Knecht, but where electrometric methods are used, frequent use is made of cadmium filters for reduction. Titrating primary amines in acid solution with sodium nitrite a sudden rise in potential is obtained with the first drop in excess of the latter.

For the estimation of free halogens an example was given of the estimation of 0·1 per cent. of bromine in sodium chlorate by distillation with hydrochloric acid followed by titration with arsenious acid.

An especially resistant electrode for the estimation of insoluble oxides is obtained by passing an alloy of 90 per cent. gold with 10 per cent. copper through a bunsen flame, when it becomes covered with a thin layer of a copper oxide.

In conductivity titrations the conductivity usually changes sharply enough to indicate the end-point, but where weak acids are concerned care must be exercised. Use is made of a Wheatstone bridge and an alternating current. The millivoltmeter may still be used by the introduction of a rotating switch, the poles in the solution being changed six to eight times a second. The current then becomes virtually a continuous one. The method is the best one for alkaloids and also for water in organic liquids. An example of the latter is the estimation of water in so-called absolute alcohol. A salt is added which completely ionises in aqueous solution, *e.g.* potassium perchlorate. The alcohol is rapidly stirred and the conductivity measured. The solubility of the salt is a linear function of the water present, and from an examination of the curves obtained its content may be deduced. Conductivity methods are excellent for determining and comparing the hardness of waters.

The last few years has seen the replacement of electro-deposition methods by titration methods, and very accurate results may now be obtained even with the simplest equipment. The behaviour of titration electrodes requires further study, and from the work now being carried out on surface adsorption and surface actions in general, much progress may be expected in the future.

L. G. R.

[1] Synopsis of a paper presented to the Manchester Sections of the Society of Chemical Industry, Society of Dyers and Colourists, Institute of Chemistry, and the Manchester Literary and Philosophical Society, on November 2, by Prof. W. D. Treadwell of the Technical Highschool, Zürich.

University and Educational Intelligence.

CAMBRIDGE.—The Right Honourable S. M. Bruce has been elected an honorary fellow of Trinity Hall. Mr. P. J. Durrant, Corpus Christi College, has been elected fellow and lecturer in natural sciences at Selwyn College. Mr. R. H. Fowler, Trinity College, has been appointed University lecturer in mathematics.

The desk habitually used by Francis Maitland Balfour and afterwards by Sir Michael Foster—two of the chief founders of the Biological Schools of the University—has been presented by Dr. Michael Foster to the Balfour Library.

The Annual Report of the Special Board for Agriculture and Forestry shows a falling off in the number of students from the excessive numbers immediately after the War. Amongst the notable events in the year's working of the department are included the completion of the purchase of the University farm, the foundation of the professorship of animal pathology, the organisation of the Horticultural Research Station, and the addition of Poultry Sections to the Animal Nutrition Institute and the Genetics Institute.

Trinity College announces a research studentship open to graduates of Universities other than Cambridge, and also exhibitions open to students at present studying at Dominion or Colonial Universities.

DURHAM.—The Newcastle and Gateshead Water Company have granted the sum of 100*l*. to Mr. B. Millard Griffiths, lecturer in botany at Armstrong College, Newcastle-upon-Tyne, to enable him to carry out further researches on the micro-flora (phytoplankton) and the hydrography of the smaller bodies of fresh water.

EDINBURGH.—On November 12, the Right Hon. William Lyon Mackenzie King, Prime Minister of Canada, and the Hon. William Robertson Warren, Prime Minister of Newfoundland, received the honorary degree of LL.D. At the close of the ceremony, Mr. Mackenzie King delivered a short address on the Imperial Conference, which, he said, had proceeded on sound constitutional lines that would be enduring in the development of the political evolution of the British Empire.

LIVERPOOL.—The late Mr. William Prescott has bequeathed 20,000*l*. to the University to found a chair of agriculture or a chair for the furtherance of one or more of the following subjects, namely, the chemistry of agriculture, the cultivation of land, the care, breeding and raising of crops, the diseases of crops, or any other subject connected with agriculture. The University is given twelve months in which to decide whether or not it can accept this gift.

Mr. William Horton has been appointed honorary lecturer in plant histology.

MANCHESTER.—Prof. A. V. Hill has presented a sum of 200*l*. to endow a prize to be awarded for an essay on a biochemical subject.

Mr. Edgar Morton has been appointed assistant lecturer in economic geology.

The following have been elected to honorary research fellowships: Dr. E. D'Arcy McCrea, in physiology; Mrs. Gertrude Robinson, in chemistry; Mr. W. K. Slater, in chemical physiology.

THE Universities of Brussels and Montreal both report gifts of radium among their benefactions during 1922–23. The former participates in a gift of 8 gm. by a mining company to the universities of Belgium, and the latter has been entrusted by the Government of the Province of Quebec with $1\frac{1}{4}$ gm.

ACCORDING to the *British Medical Journal*, honorary degrees will be conferred on November 24 by the University of Paris on the following distinguished men of science: Sir J. J. Thomson; Prof. Camillo Golgi, emeritus professor in the University of Pavia; Dr. W. W. Keen, formerly professor of surgery in the Jefferson College, Philadelphia, and Prof. S. A. Arrhenius, of Stockholm.

A CLARENCE GRAFF fellowship, tenable for one year by a British graduate of Oxford or Cambridge at any American university located between the Allegheny and Rocky Mountains, has been founded by Mr. Graff, an American banker resident in London. The object of establishing the fellowship, which carries a stipend of 250*l*. plus tuition fees, is "to foster a better understanding in Great Britain of social conditions and currents of opinion in the United States of America." The award will be made by a committee consisting of the secretary of the Universities' Bureau of the British Empire, the director and assistant director of the American University Union in Europe, and the vice-chancellors of the Universities of Oxford and Cambridge, and preference will be given to a student of humanitarian studies. Earlier this year (May 5, p. 621) we referred to the foundation of Henry P. Davison scholarships at American universities for Oxford and Cambridge men, and it is noteworthy that in each case the gifts have come from Americans. They will help to swell the very small number of awards at American universities available to British students compared with the 96 Rhodes scholarships at Oxford for Americans.

PARTY politics have no place in the columns of NATURE, but we are concerned with what is promised or performed by our statesmen or politicians on behalf of scientific progress. We are, therefore, interested in the election address which Mr. H. G. Wells, as Labour candidate for the University of London constituency, has issued, together with a report of a speech on "Socialism and the Scientific Motive." The Labour Party believes, he says, in science and in the scientific motive as a motive altogether superior to profit-seeking. He appeals to university people as people who know something of the work of scientific investigators, artists, men of letters, teachers, and medical men; who know that none of these work for profit or on the profiteering system, but for service, and that the work they do is infinitely better and more devoted than the work that men do for the profit-making motive. This knowledge should enable them to see that if, in accordance with the doctrines of Labour Party Socialism, collective ownership were to replace private ownership in nearly all the common interests and services of the community, these things would be better managed, especially as the Labour Party recognises "the supreme need of scientific knowledge and the necessary leadership of professionally trained men . . . and teachers." The argument is not altogether convincing, but Mr. Wells is at any rate capable of the philosophic point of view, and if he controlled the policy of the Labour Party, universities would not need to fear inconsiderate treatment at the hands of a Labour Government. One wonders, however, how far his attitude would be likely to be adopted by the people who would determine the policy of such a government. Some of the remarks by Labour members in the House of Commons debate on the Oxford and Cambridge Universities Bill were the reverse of reassuring on this point.

Societies and Academies.

LONDON.

Royal Society, November 15.—Sir William **Bragg** and G. T. **Morgan**: Crystal structure and chemical constitution of basic beryllium acetate and propionate. Basic beryllium acetate is shown by X-ray analysis to be a highly co-ordinated compound. The molecule is a perfect tetrahedron, having an oxygen at the centre, a beryllium alone at each corner, and an acetyl group associated with each edge. The crystalline structure is the same as that of diamond. The propionate forms a monoclinic crystal. The propyl group can no longer be arranged so as to possess a plane of symmetry, as in the case of the acetyl; and in consequence the symmetry is much less.—G. I. **Taylor**: Experiments on the motion of solid bodies in rotating fluids.—L. C. **Jackson**: Investigations on paramagnetism at low temperatures. Pt. I. Powdered substances. The following paramagnetic substances have been investigated from atmospheric temperature down to the lowest temperature obtainable with liquid hydrogen (about 14° K): anhydrous sulphates, heptahydrated sulphates and ammonium double sulphates of cobalt, nickel, and ferrous iron. These substances follow the Weiss law $\chi(T+\Delta)=C$ at relatively high temperatures, but at the lowest temperatures, (1) susceptibility increases more rapidly with fall in temperature than is given by Weiss law, and (2) the curve of $1/x$ against T possesses a point of inflection; a maximum and a minimum value of susceptibility occur in the region of lowest temperatures. Pt. II. Crystals. The principal susceptibilities of crystals of cobalt ammonium sulphate and nickel sulphate (heptahydrate) have been determined over a temperature range of 290° K down to 14° K. The Curie constant C is same for each of the principal susceptibilities of any crystal. Deviations from the Weiss law in the case of cobalt ammonium sulphate fall into category (1) above, while those of nickel sulphate fall into category (2).—L. C. **Jackson** and H. Kamerlingh **Onnes**: The magnetic properties of some paramagnetic double sulphates at low temperatures. The magnetic susceptibilities of powdered cobalt potassium sulphate, cobalt rubidium sulphate, manganese ammonium sulphate, have been measured at temperatures from atmospheric temperature down to about 14° K. The two cobalt compounds confirm the results given above for cobalt ammonium sulphate. Manganese ammonium sulphate obeys the Curie law, $\chi T=$const., down to the lowest temperature investigated. This result fits well with the known behaviour of other manganese salts, showing that in this series of compounds the substance follows Curie's law more closely the greater its "magnetic dilution."—H. H. **Potter**: Some experiments on the proportionality of mass and weight. The gravitational accelerations of lead, steel, ammonium fluoride, bismuth, paraffin wax, duralumin, and mahogany have been compared with that of brass, and no difference greater than that attributable to experimental error has been found. An accuracy of one part in 50,000 has been obtained. Special attention has been given to two substances, ammonium fluoride and paraffin wax, which have large hydrogen contents.—Lord **Rayleigh**: Further studies on the glow of phosphorus and its extinction by moist oxygen. The velocity of blast necessary to blow away the glow of phosphorus increases enormously with rise of temperature. On the other hand it is enormously diminished by enriching the air blast with oxygen. In either case the range examined was of order 1000 times. This velocity of blast measures rate of propagation upstream of glow through mixture of phosphorus vapour and oxygen. Where the velocity is reduced, by cooling or by adding oxygen, to less than 1 cm./sec., the condition of extinction is approached. From this viewpoint the known extinction by moist oxygen alone is the limiting case of slow propagation. Hence extinction is due to failure of the process causing propagation, probably a catalytic action of products of combustion. Excess oxygen, like other inhibiting substances, "poisons" these products.—H. A. **Wilson**: An experiment on the origin of the earth's magnetic field.—H. **Robinson**: The secondary corpuscular rays produced by homogeneous X-rays. The Robinson-Rawlinson method of investigating velocities of secondary cathode rays produced by X-rays has been developed with the view of increased accuracy. Special attention has been paid to homogeneity of the primary X-ray beam. The velocities of secondary electrons are measured by deflexion in the magnetic field of a pair of large Helmholtz coils. The copper K_a rays are used as primary X-radiation. Five of the N absorption edges of bismuth have been measured, the remaining two not being separated from the O rings. All five M edges have been measured for atoms as light as tungsten. The L limits have been measured as far as copper, and the K limits to oxygen. Progressive changes occur along the series of elements in the relative intensities of different members of the same group.—J. W. **Gifford**, with an introduction by T. M. **Lowry**: Some refractive indices of benzene and cyclohexane.—J. A. V. **Butler**: A note on the significance of the electrode potential. A thermodynamical argument given in Heyrovsky's paper on the significance of the electrode potential contains stages of the cyclic process employed which are irreversible; hence the conclusions are erroneous. When the cyclic process is conducted reversibly, the sum of the differences of potential round the cycle is zero; therefore no information regarding the relations between the electrode potentials and the various chemical equilibrium constants is obtained by the use of a cyclic process of this kind.

Mineralogical Society, November 6 (Anniversary meeting).—Dr. A. Hutchinson president, in the chair.—L. J. **Spencer**: Euclase and platinum from diamond-washings in British Guiana. Small disks resembling fossil corals consist of a radial aggregation of euclase crystals so arranged that the plane of symmetry is always parallel to the surface of the disk. These, together with tourmaline, diamond, gold, and platinum, were found in the conglomerates near the Kaieteur Falls on the Potaro River. Platinum has not hitherto been recorded from British Guiana.—H. E. **Buckley**: Some anomalous optical properties of freshly-prepared mixed crystals of the Seignette salts. In the orthorhombic and isomorphous Seignette salts the sodium-potassium tartrate has the optic axial plane parallel to the brachy-pinacoid, whilst in the sodium-ammonium salt it is parallel to the macropinacoid. Mixed crystals of the two salts show, as would be expected, the optic axes for different colours in two planes at right angles (as in brookite), but only after the crystals have been prepared for some time. Freshly-prepared mixed crystals exhibit crossed dispersion of the monoclinic type (as in borax). A maximum angle of 75° between the axial planes for red and violet light is given by crystals containing 45 per cent. sodium-potassium tartrate. On standing, the axial planes slowly migrate to the planes of symmetry, and equilibrium is established in from two to thirteen weeks, this

being hastened by increasing the temperature.—N. T. **Belaiew**: On the genesis of Widmanstätten structure in meteorites and in terrestrial alloys. The Widmanstätten structure belongs to the triad of secondary structures, the other two being the structure of large crystals and the network structure. Under suitable conditions either of these structures may occur in iron-carbon alloys or in any other alloys crystallising in the face-centred cubic lattice and exhibiting the same kind of equilibrium diagram. As the diagram of the iron-nickel alloys is quite similar to that of iron-carbon, the same kind of crystallisation may be expected in both cases and also in meteorites. The well-known Widmanstätten figures in meteorites are also arranged in a Widmanstätten structure, and the conditions to which they owe their appearance are a very slow cooling after solidification in the granulation zone and a relatively rapid separation of the constituents afterwards in the zone of secondary crystallisation leading to their lodging themselves parallel to the octahedral planes in every granula.—L. R. **Wilberforce**: Illustration and detection of inclined and horizontal dispersion in bi-axial crystals. If the optic picture of an ordinary bi-axial crystal is viewed through a prism the refracting edge of which is parallel or perpendicular to the axial plane, the appearances characteristic of horizontal and inclined dispersion respectively are produced. Such dispersions in a crystal, if too small to be detected by direct observation, can be discovered by thus using a prism of small angle alternately to reinforce and oppose them, and noting the want of symmetry in the effects produced. —A. **Russell**: On the occurrence of the rare mineral nadorite in Cornwall, and of beraunite (eleonorite) in Co. Cork, Ireland. A single specimen of the rare mineral nadorite was found at the small antimony mine Bodannon, St. Endellion, Cornwall. It forms aggregates of nearly square platy crystals, transparent, of a yellowish-brown to reddish-brown colour, occupying a cavity in fibrous jamesonite. The crystals are combinations of *a* (100) and *r* (130) and are twinned on *l* (011). A very well-defined specimen of the variety of beraunite known as eleonorite, found at the iron and manganese mine of Roury Glen, Glandore, Co. Cork, consists of a mass of diverging fibrous crystals of a reddish-brown colour, between walls of limonite. The fibres are elongated in the direction of the *b* axis and show very strong pleochroism.—A. F. **Hallimond** and F. R. **Ennos**: On stilpnomelane, from North Wales. A dark scaly vein-mineral, strongly resembling biotite, proves on analysis to contain very little potash, and is very similar in physical properties to stilpnomelane from Moravia. The composition appears to be $6SiO_2 \cdot 2Fe_2O_3 \cdot 2FeO \cdot 3H_2O$; sp.g. 2·85; apparently uniaxial; o = 1·687, e = 1·595; pleochroic, o = dark brown, e = pale yellow; brittle, with eminent basal cleavage and marked cleavage normal to this, yielding pleochroic chips; H = 3·5; insoluble in hot N/2 HCl. —G. T. **Prior**: On the chemical composition of the Ashdon meteorite: This meteoric stone which fell at Ashdon near Saffron Walden, Essex, on March 9, 1923, is a white hypersthene-chondrite containing 8¾ per cent. of nickeliferous iron in which the ratio of iron to nickel is about 6 to 1.

CAMBRIDGE.

Philosophical Society, October 29.—Mr. C. T. Heycock, president, in the chair.—W. J. **Harrison**: On the motion of spheres, circular and elliptic cylinders through viscous fluid.—E. A. **Milne**: On the derivation of the equations of transfer of radiation and their application to the interior of a star.—F. P. **White**: (1) The conics through fives of six points. (2) Certain nets of plane curves.—C. G. **Darwin** and R. H. **Fowler**: Some refinements of the theory of dissociation equilibria.—J. C. **Burkill**: The fundamental theorem of Denjoy integration.—D. R. **Hartree**: On the correction for non-uniformity of field in experiments on the magnetic deflexion of β-rays.—T. M. **Cherry**: On the solution of certain difference equations.—W. **Burnside**: On the formulæ of one-dimensional kinematics.—W. P. **Milne**: Note on the twelve points of intersection of a quadri-quadric curve with a cubic surface.—E. S. **Bieler**: The effect of deviations from the inverse square law on the scattering of α-particles.—W. M. H. **Greaves**: The stability of the periodic states of the triode oscillator.—D. **Keilin**: The structure and life-history of Lipotropha n.g., a new type of Schizogregarine, parasitic in the fat body of a dipterous larva (Systenus).

MANCHESTER.

Literary and Philosophical Society, November 6.—R. H. **Thouless**: The psycho-galvanic phenomenon. The psycho-galvanic phenomenon is the change which takes place in the bodily resistance during emotion. It may be measured by placing electrodes on the palm and back of the hand, and balancing the resistance so obtained in a Wheatstone bridge circuit. The threat to prick the subject with a pin may produce a reduction of more than 1000 ohms in a total resistance of 12,000 ohms. The exact physiological change producing this result is not known, but we are clearly measuring one of the many involuntary bodily changes which accompany emotion. One person may react much more readily than another. Possibly this may be due to differences in temperament or to such prosaic causes as differences in the dryness of the skin. Similarly, differences in the resistance changes of the same person on different days are as likely to be due to simple physiological changes as to differences in his mood. What may reasonably be assumed is that one person during the course of one sitting gives greater resistance changes for greater emotion and vice versa; though after a resistance change, there is a long period of slow recovery, and the extent of a new deflexion probably depends in part on what stage in recovery has been reached.

PARIS.

Academy of Sciences, October 29.—M. Albin Haller in the chair.—The president announced the death of M. Maurice Leblanc, member of the section for the application of Science to Industry.—J. **Costantin** and L. **Dufour**: A secondary disease of the oak caused by *Polyporus* (*Phellinus*) *rubriporus*. The growth of this fungus is very slow, attacking the tree always near the soil level. Details are given of thirty-two trees attacked by this disease. Owing to its slow growth and the fact that the fungus can enter the tree only at a damaged spot, the disease is unlikely to prove troublesome.—Viggo **Brun**: The direct study of Riemann's $f(x)$.—A. **Guillet**: The mechanical determination of the relative course of two pendulums. A comparator with a chronometric motor.—A. **Damiens**: The dynamic allotropy of mercuric iodide. The author has repeated some recent experiments of Smits and Bokhorst on the change of the red into the yellow varieties of mercuric iodide. While the experimental results agree, under certain conditions, the author's interpretation differs entirely from that of the above workers. The necessity for a new theory of allotropy

does not appear to be proved, and the characteristics presented by the allotropy of mercuric iodide can be readily explained by the usually accepted theory.—René **Audubert**: The action of light on metal electrodes with small solution pressures.—André **Graire**: The estimation of sulphonitric and sulphonitrous acids. None of the methods of analysis of commercial products in general use gives satisfactory results. The author gives a preference to the Schloesing method with ferrous chloride.—M. **Bourguel**: The action of sodium amide on the chlorides derived from an aldehyde or a ketone by the use of phosphorus pentachloride. Sodium amide is a more satisfactory reagent for the removal of hydrochloric acid from these chlorine compounds than dry potash or alcoholic potash. The yields are higher and the products purer.—V. **Crémieu**: The variation in the composition of gases spontaneously evolved from thermal springs produced by earthquakes.—V. **Agafonoff**: The limit of the accumulation of humus in soils, with reference to observations on soils of the Nièvre.—G. **Pontier**: The fossil elephants of England: the mammoth in England and in the North Sea.—V. **Lubimenko** and Mme. S. **Fichtenholz**: Contribution to the study of the physiological rôle of the nervation of leaves. The main function of the nervation of the leaf is the mechanical support of the limb. The transport of water is only a minor function.—E. **Aubel** and R. **Wurmser**: The formation of glucose at the expense of alanine and of lactic and pyruvic acids. Experiments on dogs proved that 92 per cent. of alanine and lactic acid are transformed by the animal into glucose, but that in the most favourable case only 80 per cent. of the pyruvic acid underwent this transformation.—A. **Quidor** and Marcel A. **Hérubel**: The psycho-physiology of the visual phenomena in animals.—H. **Barthélémy**: The impregnation of the uterine eggs of *Rana fusca* and of *Bufo vulgaris* after immersion in water or in aqueous solutions of common salt.—J. **Bridré** and A. **Donatien**: The micro-organism of contagious agalaxy and its culture *in vitro*. Cultures of this organism have been made in tubes, details of the technique followed being given. The activity of the cultures was proved by experiments on sheep and goats. The organism was visible after staining by the slow method of Giemsa, after fixing the colour (May-Grünwald).—MM. **Brocq-Rousseau**, **Forgeot**, and **Urbain**: Serotherapy against glanders in the horse.

Industrial Science.

THE appearance of the eighth annual report of the Department for Scientific and Industrial Research brings with it the reminder that time passes, and tells of much useful work performed. As usual, the report is divided into three sections: the report of the Committee of Council, the report of the Advisory Council of the Committee, and a summary of the work of the Research Boards and Committees of the Department with numerous appendices. The first section, in the main a formal résumé of the work done, records with apparent satisfaction a reduction of the estimates by some 20,000*l.*, a regrettable fact, in spite of the urgent need for economy, for wise expenditure in the application of science to present conditions might easily result in savings of far greater amount. After reference to the valuable work of the co-ordinating research boards established to connect the work of the scientific departments in the various services, both together and also with university and other scientific activities, the report directs attention to the fact that the Research Associations, supported out of the Million Fund, are approaching the end of the five years for which grants were made, and states the policy which, on the advice of the Advisory Council, has been adopted. "It must not be assumed," the report continues, "that further financial assistance will be recommended in every case. There will have to be ample proof that the industry is unable immediately to shoulder the entire responsibility, and further aid will only be given if the industry concerned is prepared to make a rapidly increasing effort towards complete responsibility."

Another direction in which the committee has taken an interesting step in its task of co-ordinating the scientific activities of the government departments is in the promotion of a joint exhibit at the British Empire Exhibition next year. After various consultations it has been agreed that there should be a central building in which the government departments concerned will arrange their exhibits, working in conjunction with a committee organised by the Department of Overseas Trade, while the Royal Society, financed by a grant from funds allocated by government, has assumed responsibility for an exhibit illustrating recent advances in pure science.

The report also records the fact that the French Government has established under the Minister of Public Instruction an *Office National des Recherches Scientifiques et Industrielles et des Inventions*, having objects much resembling those of the Department.

Turning now to the report of the Advisory Council, the ground covered is very extensive, the Research

Associations, the co-ordinating boards, the research boards, the National Physical Laboratory, the various other research institutions, and the organisation controlling grants to individual workers, are all passed in review. On the whole the record is one of continuous progress. Difficulties have been overcome and advances made in many directions. The Fuel Research Board has been weakened by the retirement of Sir George Beilby, who has for seven years guided its activities "and laid the foundations of a structure of new knowledge of great significance for the health and industrial welfare of this country." Dr. Lander succeeds him as director, while Sir Richard Threlfall becomes chairman of the Board. The gratifying fact is recorded that, at the International Conference on Radio-Telegraphy at Brussels last year, the programme of work prepared for the British delegates by the Radio Research Board found a ready acceptance as the basis of international research.

The appointment of Sir William Bragg to the Fullerian professorship at the Royal Institution is noted, and the arrangements by which he is to have the help of a staff of skilled assistants are referred to. Both he and the Advisory Council are to be congratulated on this; we may look forward to the Royal Institution and the Davy-Faraday Laboratory becoming the birthplace of a series of discoveries no less notable than those which have already made its name famous in the annals of science.

The committee which, in co-operation with the railway companies, has been set up under the chairmanship of Sir Alfred Ewing to investigate the stresses on railway bridges due to moving loads, has undertaken a difficult but important task. The weight and speed of trains have increased many fold since most of our bridges were built. Stress conditions are much more serious, the large factor of safety designed for is much reduced, and, while there may be no grounds for anticipating serious risks, investigation and fuller knowledge are urgently needed.

Growth of another kind is indicated by the purchase of land at Teddington for extensions of the National Physical Laboratory and other government institutions.

Only in one section is the note less assuring. After describing generally the scheme under which the Research Associations were established, the report of the Council continues: "The anticipations made at the inception have failed to be realised owing in large measure to industrial events since that date." The Associations were started during the last year of the War, four being founded before November 1918. It was hoped that they would be a flourishing product of the boom which was to follow and to last for five years at least. This hope has not been fulfilled; the boom lasted two years, during which period seventeen associations came into existence. Since 1920, a period of intense depression, only one has been added to the list. The five years for which the grants were made are now coming to an end; funds are running out. The Associations are financed from the Million Fund, and the question comes, What is to be done? Few if any really can stand alone; what is their record? Is it sufficiently promising to justify further State assistance even if it be possible to find the money? The Advisory Council has considered the facts, and, while realising that "the five years of grant appear likely to be insufficient in many cases to fulfil the original hopes of the scheme," has decided that there is no justification for continuing the original contracts. Existing agreements, therefore, are to be terminated at the end of the quinquennial period; should any association apply for a further grant, the case will be considered on its merits and an inquiry will be made into the circumstances. New grants may as the result of this be made, but in no case, it is held, should the grant extend for more than an additional five years.

The position is a difficult one; the circumstances of the past three years have been such that the scheme has not had a fair chance. What will the chances be in the next five years? The inquiries to be set on foot will throw some light on this question, and the plan proposed is probably the best that can be devised. But there are other difficulties, as the report points out. Scientific inquiry is coming to be recognised more and more as the basis on which advance in industry rests, while the calls of industry are no small inducement to science to advance. But co-operation in industrial investigation is novel. In Germany, in pre-War days, great firms could maintain their staffs of skilled workers; the same is possible in America now; but there are few concerns in England so large and so flourishing as to bear the expense of a private research laboratory. Such can probably be counted on the fingers of one hand; the Brown-Firth laboratories, the G.E.C. works at Wembley, and the laboratories of Barr and Stroud are well-known examples. Such firms do not participate in the work of the Associations; and among those who do the differences of position are very marked. By some the need of scientific inquiry is fully grasped: others have scarcely realised it. Some through long experience have gained a store of useful practical knowledge; why should they share it with others less happily placed? We give much, we gain little, they may not unnaturally say; wherein do we profit?

Yet we find that where there have been mutual trust and confidence; where each member of an Association

has been willing to give of his best, anxious to improve the common stock of knowledge and to profit by the new knowledge placed at his disposal by the research staff, the Association has prospered most; the firms which knew most have learnt more, and it has not been a question of giving everything, receiving nothing. Time only can solve the question. We may be allowed to hope that, as the welfare of its citizens depends on the prosperity of a State as a whole, so the advances of industrial science will benefit the whole industry, and not least those who by previous knowledge and experience are most able to profit it by them.

Popular Astronomy.

(1) *The Star People.* By Gaylord Johnson. Pp. xi + 107. (London: Methuen and Co., Ltd., n.d.) 4*s.* 6*d.* net.

(2) *The Vault of Heaven: An Introduction to Modern Astronomy.* By Sir Richard Gregory. Second edition, rewritten. Pp. vii + 202. (London: Methuen and Co., Ltd., 1923.) 6*s.* net.

(3) *The Heavens and their Story.* By Annie S. D. Maunder and E. Walter Maunder. Pp. 357. (London: The Epworth Press, n.d.) 4*s.* net.

(4) *The Kingdom of the Heavens: Some Star Secrets.* By Charles Nordmann. Translated by E. E. Fournier d'Albe. Pp. 262. (London: T. Fisher Unwin, Ltd., 1923.) 12*s.* 6*d.* net.

THE practically simultaneous appearance of four books, all written mainly with the object of making available the fundamental truths of astronomy, demonstrates alike the eagerness of the public to be informed and the willingness of those qualified by experience to minister to this praiseworthy curiosity. Naturally, there is much repetition; the same facts, or many of them, appear in each of the several volumes, but the method of presentation varies according to the assumed intelligence of those addressed.

(1) In the first, Mr. Gaylord Johnson addresses an audience of children and adopts kindergarten methods with the object of teaching them how to recognise and identify the constellations. The method is novel and, if it prove successful, we imagine that the ability of the teacher, the gift of creating interest in what is unfamiliar, the power of rapidly comprehending the direction of a child's thoughts, and the art of giving it expression will play as great a part as the ingenuity exhibited by the author of the scheme. Mr. Johnson's book may act as a stimulant, but against one danger we may utter a word of warning—the attempt to recollect too many stars and their delineations. This is an error into which we think the author has fallen. Many of the stars depicted are too faint, some of the fourth and lower magnitudes being included. Such faint stars might be allowed in groups, as in the Pleiades, but for isolated stars it is doubtful whether any below the second should be included. But adherence to such a rule would have prevented the drawing of the outline of the constellation figures, and this feature is naturally relied upon to increase the interest of the children.

(2) A second edition of "The Vault of Heaven" has long been needed. This early work from Sir Richard Gregory has been a warm favourite with the writer of this notice, who has lent it to many students anxious to become acquainted with the plan of the solar system and the constructive machinery of the stellar universe. Whether from politeness or conviction, all have expressed approval, and it is to be hoped that another generation will find equal pleasure with the contents.

This new edition, written up to date, serves a further purpose to those who have read the earlier. They will learn what has been accomplished by the improvements in the construction of instruments, and the continuous application of these potent engines of research to the study of the heavens. Spectroscopy and photography have advanced by leaps and bounds in the interval, and much information that was hoped for, but seemed outside the reach of human effort, has become part of the general stock of knowledge. The drift of the stars through space, the dimensions of the whole stellar universe, the growth and decay of worlds, with much else that invited speculation, have become certainties, and a new set of problems lies before the astronomers of the future, though it must be admitted some of the older and apparently simpler problems still stand tantalisingly on the border-land of the unknown, and individual judgment may interpret the evidence as temperament dictates. Among these may be placed the "canals" of Mars and the theories built on them, the varying appearances on the lunar surface, which Prof. W. H. Pickering and others have noted to recur with a regularity that betokens a cosmic cause. Concerning the correct interpretation of the observations, Sir Richard Gregory preserves a judicial attitude, presenting the evidence impartially, and leaving the verdict to the decision of instructed opinion. The class for whom the book is intended is clearly indicated, and this class should benefit from the well-arranged and accurate contents.

(3) We confess that we have read this book with no small measure of surprise, for it is apparently put forward as a recent compilation. It bears no date, and there is no suggestion that it is a reprint of an ancient work. But such well-informed authors could not, if the work were new, refer in the preface to the late Sir W. H. M. Christie as the Astronomer Royal, and afterwards

in the text discuss the possibility of Halley's comet being seen at its return in 1910, so that we can only conclude that it is not new. The book is intended for those who are unacquainted with astronomy, and in the early chapters is traced the method by which the ancients, unassisted by telescopes or measuring apparatus, may have gleaned their notions of astronomy. The plan is not original, but is well thought out, and suggests one of the most desirable methods of obtaining an insight into the geometry of the earth's surface. Later, the sun and planets are described as they are seen in a telescope, and the plan becomes that of ordinary descriptive astronomy. One of the authors is chiefly responsible for the discussion of the influence of sun-spots on the earth's magnetism, but we do not find the argument convincing, and additional facts have been brought to light that are not mentioned. In the concluding section reference is made to the stellar universe, but the more recent facts connected with its structure and dimensions are necessarily excluded.

(4) When so many authors are eager to put the facts of descriptive astronomy before an English public, there does not seem room for a translation. But Dr. Nordmann's work deserves a welcome reception, for it differs in some essential points from the ordinary popular treatise. His object, he tells us, is "to relate some of the marvels which the heavens have revealed to us lately. I shall speak not to instruct or amuse, but to produce thoughts, and even dreams, if I can." He bids us to expect neither the commonplaces of numerical detail nor the inane vapourings evoked by the study of the skies. Nevertheless, we are allowed to study the sun, though the magnetic and electric influences it exerts are insisted upon more than the grosser and obvious service of a centre of attraction, or the dispenser of light and heat. Similarly, the question of the habitability of the planets acquires more interest than the puzzling red spot on Jupiter, or the canals of Mars, which latter are distinctly pronounced a mirage. Thence we proceed to the stars, and are taught how to measure the distance that separates them from us. A most instructive study, clear and logical, is given of the theories of star drift, of island universes, giant and dwarf stars, and the general views that obtain of the stellar cosmos. But our author must indulge in a final paradox. He finds it in the rotation of the earth. He furnishes a dozen "proofs" that the earth turns on its axis and fearlessly faces the consequences of accumulation. The conclusion drawn is: that the earth turns and the earth does not turn are, kinematically speaking, equally true. "It is simply more convenient to suppose that the earth turns." But these be difficulties that cannot be explained in a small space.

Oceanography.

Founders of Oceanography and their Work: an Introduction to the Science of the Sea. By Sir William A. Herdman. Pp. xii + 340 + 29 plates. (London: E. Arnold and Co., 1923.) 21*s*. net.

AT the meeting of the British Association in Liverpool last September, it was mentioned that a new book on oceanography, by Sir William Herdman, had just been published. To the circle of marine workers this was something of an event, and now that the volume is before us we see that our anticipations concerning it are realised in full. In the preface—a section eminently worthy of attention in itself, and by no means to be skipped—we are informed that the book is based upon a course of about twenty public lectures given in 1919-20, while Sir William held, for the first year, the newly established chair of oceanography at the University of Liverpool. This at once explains the structure of the book and the arrangement of the subject matter, which differs from that of the ordinary text-book. The author's opening words are, "This is not a text-book of Oceanography," and he proceeds to express his doubts as to whether the time is yet come in oceanography to write "the comprehensive text-book drawing conclusions from various branches of science—ranging from astronomy to biology." In this the author is probably right, quite apart from the fact that there is scarcely a man at the moment who could do it satisfactorily.

Sir William Herdman's book may best be characterised as a series of oceanographical essays, more or less independent one of another, and dealing with persons and themes, for the most part those in which the author is himself specially interested, or in regard to which he possesses first-hand knowledge.

The book contains seventeen chapters and an appendix. Of these, the first six or seven are devoted to some of the leading lights of oceanography, their life and work, especially Edward Forbes, Wyville Thomson, John Murray, Alexander Agassiz, Prince Albert of Monaco, and Dr. Anton Dohrn. The last ten chapters deal with various oceanographical subjects, namely, hydrography, ocean currents (the Gulf Stream), submarine deposits, coral reefs and islands, luminescence in the sea, plankton—its nature, investigation, variations, and problems—applied oceanography, the sea-fisheries, and food-matters in the sea.

In these many and diverse fields the author proves himself an admirable guide—one who understands the art of making the subject interesting to his readers. The book is one of great freshness and charm, much of which is due to the impress of the author's personality; it bears throughout the mark of his own keen interest

in the science to which his life has been so zealously devoted. As a consequence, the book is never dull, even when treating of somewhat more recondite themes, and in many parts the presentment attains a degree of interest positively absorbing. Moreover, the treatment of the subject matter is sober and objective, as indeed one has a right to expect from an authority of so much knowledge and experience. We are struck not only by the author's enthusiasm for the problems themselves and for their extensive scope, but also by his practical recognition of their limitations; we feel safe in his guidance, because we feel he has the faculty of estimating values, of discriminating between the essential and the unessential. The author never attempts to conceal the limitations of our present knowledge; but he believes in the great future of oceanography, in the wealth of stimulating discovery which the science, still in its youth, has yet in store for mankind; and he contrives to inspire his readers with the same faith. But, like the practical man he is, he sees also that oceanography has other and more direct tasks before it in the service of humanity. He realises that it is this and this alone which can help us to exploit—or husband—the treasures of the sea better than we are able to do at present; that oceanography, as he aptly puts it, will help man in the future to become "less of a hunter, and more of a farmer of the sea."

The author has had the good fortune to come into personal contact with some of the greatest oceanographers; and he tells of them, giving his impression of their personalities in a most attractive manner. We are led to realise how much the influence of these men, especially Sir Wyville Thomson and Sir John Murray, meant to the author himself, and we should be grateful that he has not consigned his impressions to oblivion, but enabled younger generations of oceanographers to partake, as it were, in some degree in the life and happenings of the days when modern marine research was first created.

It is out of the question here to enter upon any detailed appreciation of the individual sections of Sir William Herdman's book; but if any parts should be noted as particularly valuable, they are chapters like the two on Wyville Thomson and John Murray, and the three on plankton and food-matters in the sea; the hydrographical sections, on the other hand, scarcely come up to the same level. For the rest, adverse criticism must be directed not so much towards what the book contains as to what it does not.

There are not a few writers who regard oceanography as being merely the study of physical and chemical conditions in the sea. Sir William Herdman is not one of these. To him, the biology of the sea is as much oceanography as are its physics, chemistry, and geology. I am entirely of the same opinion. On the other hand, I cannot but feel that hydrography has here been rather left out in the cold. Two chapters (viii. and ix.) out of seventeen, and 37 pages out of 329. This seems rather scant measure, even for those more interested in the biological side, and even granting that hydrographical observations occur here and there in the other chapters.[1] Also, the extensive work which has been carried out during the last thirty years by national and international investigations of the sea, in procuring information as to the food fishes, their development and life-histories, might, I think, have been found deserving of fuller and more particular treatment. The same applies to several institutions the principal task of which consists in working at the practical application of oceanography; in a book strongly emphasising the importance of this side of the work, they might have deserved special mention, whether for their particular organisation, or as having been of fundamental value to the methods of applied oceanography.

Nevertheless, though we might thus have wished for more, the author gives us, even without it, very much indeed, and there is every reason to congratulate him on the publication of this book. It is generally known that Sir William Herdman has furthered the advance of oceanography in his own country. In this book, he has not only set up a handsome monument to himself, but also—and this will doubtless please him more—has proved himself an excellent advocate for his young science of oceanography, both within and beyond the boundaries of Great Britain. JOHS. SCHMIDT.

Preventive Medicine.

An Introduction to the Practice of Preventive Medicine. By Prof. J. G. FitzGerald, assisted by Prof. Peter Gillespie and H. M. Lancaster. Pp. xx+826. (London: Henry Kimpton, 1923.) 37*s.* 6*d.* net.

THIS is the first "full-dress" Canadian text-book of preventive medicine, so far as we know, which has seen the light; and it is a happy augury of the future of public health in our sister country that so complete a book founded largely on Ontario experience should be practicable.

Dr. FitzGerald, the professor of hygiene and preventive medicine in the University of Toronto, has, with the assistance of several collaborators, focussed a vast mass of important information bearing on preventive medicine and public health, from which British

[1] Apropos of hydrography—one pious wish from a non-British reader: that one could but have those Fahrenheit degrees converted into Centigrade in all oceanographical works, British included. British workers seem to be able to reckon equally well with either—in the present work, for example, the temperatures are noted in Fahrenheit in one place, in Centigrade in another; but to the rest of us, Fahrenheit is an enormous disadvantage. I hope this heartfelt cry may find its way to British ears and hearts.

hygienists may gather many useful suggestions for improved practice.

Preventive medicine as the subject of a text-book is a title possessing some ambiguity, and one looks to the chapter headings and sub-headings to ascertain in what sense the words are used. In actual fact the contents of the words are very nearly identical with what in England is known as hygiene and public health, though this was scarcely to be anticipated. Public health more generally means that part of applied hygiene which has been introduced into the administrative machinery of our central and public-health authorities, while hygiene, although almost synonymous with preventive medicine, in most books on the subject has a more limited connotation.

The fact that a book on hygiene and public health should be called "An Introduction to the Practice of Preventive Medicine" is evidence of the expanding scope of public-health activities, which are increasingly embracing every phase and age of life. This beneficent intrusion of medicine—on its preventive side—is the subject of Prof. FitzGerald's suggestive first chapter, in which he forecasts the arrival of a time when it will no longer be said that "he was so sick he had to have a doctor," but when the physician will be engaged to keep his patient well, by supervision and advice. In view of this, extensive increases of our present services for safeguarding childbearing and childhood, and for periodical examinations at subsequent ages in life, are anticipated. The difference between insurance for medical purposes and prevention is aptly indicated in the words that the monetary and medical benefit may be used wisely or unwisely in the patient's *efforts to regain, not to maintain his health.*

Subsequent chapters deal with measures for the prevention of communicable diseases, each of some twenty or more diseases being discussed in some detail. Special space is given to the newly adopted measures for securing immunity against diphtheria by the administration of an antitoxin-toxin; and it would appear that by this means, guided by the Schick test, we have available a possibility of depriving diphtheria of all its power to kill and injure.

The chapter on tuberculosis contains much valuable information, but the statistics are not very skilfully presented. The essential point is pressed home that success cannot attend anti-tuberculosis efforts unless private physicians take an active part in the campaign, and constitute themselves leaders in the effort to protect human beings against excessive dosage of infection, whether from consumptives or from infected cows' milk.

The preventive aspects of pneumonia, of cerebrospinal meningitis, and of acute poliomyelitis are stated; and although these diseases remain among the least controllable of communicable diseases, much useful guidance is given.

Under the heading of smallpox an interesting account is given of an outbreak in Ontario in 1920–21, comprising 5078 cases with only 24 deaths. The low case mortality in this outbreak is similar to that experienced in many parts of America; and cases of a similar type have occurred occasionally in England. In other parts—usually traceable to an Eastern source in Europe, or to a Mexican source in America—the ordinary severe type of smallpox has occurred. In both types of the disease there is evidence of the protective effect of vaccination. It would appear that the mild type—which usually breeds true—is a definite mutation of the disease.

The chapter on venereal diseases gives a useful summary of its subject. The author, while non-committal on self-medication as a prophylactic, strongly urges medical treatment to any patient at the earliest possible moment after exposure to infection.

Considerable space is devoted to disinfection. Current disinfection during the course of an attack of diphtheria or scarlet fever is recognised as important, and considerable detail is given as to terminal disinfection when an attack is over. For these diseases, however, it is now recognised that, given thorough domestic cleansing, terminal gaseous or liquid disinfection of rooms does not diminish the number of recurrences of infection. The part of the book dealing with general hygiene gives full information as to water supplies, milk, foods, diet, and domestic and community sanitation, on which no special comment is needed. We note, however, that while the importance of movement of air in making the air of a room hygienic is not disputed, it is also pointed out that in conditions of overcrowding active ventilating may increase the danger of infection, by increasing the striking distance of particulate infective material, whether as dust, or as spray derived from coughing, etc.

The chapter on vital statistics contains a few minor errors. In England and Wales the geometrical method of estimating inter-censal populations is no longer adopted. No attempt is made to assess the relative value of the various tests employed in determining the health conditions of a community. Special chapters deal with the subjects of maternal and infant mortality, school hygiene, public-health clinics, and industrial hygiene, but these do not call for special comment.

On p. 673 are given interesting particulars of the amount spent per capita per annum in the various American States on health administration. The "health appropriation" varies from 30·8 cents in Pennsylvania to 2·1 cents in Texas, these sums being divisible among the following subdivisions of the Public Health Department—Engineering, Communi-

cable Diseases, Laboratory, Vital Statistics, Child Hygiene, Venereal Diseases. This table is followed by a valuable table by Dr. Chapin giving the relative value or "marks" of different branches of public-health work. It will surprise some English administrators to find plumbing and nuisances credited with 20 marks out of a total of 1000, while control of nostrums is given 50 marks, educational measures 80, and anti-tuberculosis work 140. There is much to be said for this American apportionment of merit. A number of appendices give details as to industrial hygiene, the employment of children, form of report of an industrial nurse, the Workmen's Compensation Act, housing, etc.

The book can be recommended as containing a review of recent information on most branches of preventive medicine, which would be most difficult to obtain elsewhere, except by reference to many documents.

Our Bookshelf.

Les Phénomènes thermioniques. Par Eugène Bloch. (Recueil des Conférences-Rapports de Documentation sur la Physique. Vol. 4, 1re Série, Conférences 9, 10. Édité par la Société *Journal de Physique.*) Pp. 111. (Paris: Les Presses universitaires de France, 1923.) 10 francs.

ELECTRIC conductivity and other effects produced in the neighbourhood of hot bodies are generally called "thermionic" phenomena. The author gives an interesting and clear account of several of the laws in connexion with effects that have recently been discovered by O. W. Richardson and others. In spite of the great progress that has been made, there is no indication that this mine of research is approaching exhaustion. New practical applications are being continually found. Thermionic valves are now being made by hundreds of thousands for use in radio communication, radiography (X-ray work), and for rectifying alternating currents. Notwithstanding the great practical use that is made of thermionic phenomena, we are still far from seeing how they explain contact difference theories or thermo-electricity. In particular, the theory of thermionic emission in gases gives rise to great difficulties. We have still to explain many apparent experimental contradictions. The serious study of ionisation potentials and of resonance founded on thermionic emissions has barely begun. As time elapses the theoretical field becomes more complex, but the possibilities of valuable discoveries become greater.

The Outline of the World To-Day. Edited by Sir Harry Johnston and Dr. L. Haden Guest. (To be completed in about 24 fortnightly parts.) Part 1. Pp. 40. (London: George Newnes, Ltd., 1923.) 1s. 2d. net.

THERE should be a demand for a work of this nature, which aims at giving "a clear and definite impression of the immense variety of the life and romance, the natural beauties and treasures, of other lands." The first issue contains the greater part of the section dealing with France, and is copiously illustrated with well-chosen photographs, colour plates, and coloured maps by Bartholomew. The letterpress is vivid, accurate, and sufficiently critical to give it value, but there is little attempt to describe or explain the scenery, and the maps have the defect of showing no physical features. Some attention to physical geography would not be amiss. There is no indication of the arrangement of the work except that it will "concentrate on the interesting side of nations and their lives, dealing with mankind at home . . . their joys and pleasures, their sports, their pageants, and their ideals." The authors of the various articles are not stated, but the names of the editors are sufficient guarantee that high authorities will be chosen. So far as can be judged from the first number, the work should prove of value in spreading a knowledge of the ways of other nations and encouraging an understanding of their ideals and ambitions.

The Banyankole: the Second Part of the Report of the Mackie Ethnological Expedition to Central Africa. By the Rev. John Roscoe. Pp. xii+176+31 plates. (Cambridge: At the University Press, 1923.) 15s net.

IN the second volume of the report of the Mackie Ethnological Expedition to Central Africa, Mr. Roscoe again deals with an immigrant nomadic pastoral people, ruling an earlier, or original, agricultural group. The Bahuma belong to the same stock as the neighbouring Baganda and Bakitara, but represent an earlier settlement in the Lake region. They are even more strict than the Bakitara in the observance of milk customs, and owing to their repugnance to intermarriage with their serfs, who lived on vegetable food, they are racially purer than most pastoral peoples of this area. Apart from the description of the ritual of the milk, which necessarily occupies a position in the book commensurate with its prominence in the life of the people, Mr. Roscoe's minute account of the Banyankole is a piece of work the value of which to the ethnologist it is difficult to overestimate. Not only is the culture he describes rapidly passing away, but also it embodies—as for example in its totemic system and belief in the reincarnation of members of the royal family in the forms of various animals—elements which are of great importance in the study of the development of custom and belief.

The Unconscious Mind: a Psycho-Analytical Survey. By Dr. S. Herbert. Pp. vii+230. (London: A. and C. Black, Ltd., 1923.) 6s. net.

THE output of psycho-analytic literature is always on the increase. This volume is an attempt to give a systematic account of the Unconscious on Freudian lines; and it follows the usual plan upon which such works are written, containing considerable illustration of theory from case-histories, examples of myth, wit, art, and the like. There is a good chapter on "Theories of the Unconscious," in which the leading views are stated and criticised with—naturally enough—a strong Freudian bias. On the whole, "The Unconscious Mind" is a simple and straightforward presentation (so far as the subject-matter permits of simplicity and straightforwardness) of the doctrine of the Viennese school; and can be recommended for the literary form of its presentation as well as for being—what it claims to be—"a general outline of our knowledge of the nuconscious, as hitherto ascertained."

Letters to the Editor.

Dutch Pendulum Observations in Submarines.

DR. F. A. VENING MEINESZ, commissioned by the Dutch Geodetic Committee to make pendulum observations on board the Submarine K II of the Royal Dutch Navy during the voyage from Holland to Java (see NATURE of September 15, p. 393), has sent particulars of his observations from Gibraltar, Tunis, and Alexandria.

The beginning of the voyage was extremely disappointing because of the bad weather. For the first five days the sea was continually very rough. The rolling of the ship amounted to 30° to each side, and the pitching to 8 metres; the nights had to be spent strapped to the berths. It was a very rough experience for the first stay on board a seagoing vessel.

After passing Portland Bill in the English Channel, an attempt was made to take observations. Submerged to a depth of 20 metres, the rolling still amounted to $\frac{3}{4}$° to each side, which made observations impracticable. At length, off the Portuguese coast, the weather cleared and it became calmer, but the long swell continued. On September 24 an inquiry was made again into the movements of the submerged ship. The greatest angle of inclination caused by the pitching amounted at the sea-surface to 1°, the rolling to 6° to each side. At a depth of 30 metres, and while the vessel was going in the direction of the swell, the inclination caused by the pitching was at most $\frac{3}{4}$°, which by the use of the horizontal rudder could be reduced to less than $\frac{1}{4}$°; but as the rolling was still $1\frac{1}{2}$° to each side, observations were practically impossible.

Notwithstanding the considerable rolling of the ship, the amplitudes of the pendulums appeared to vary fairly regularly. The principal impediment was the circumstance that the rays from the electric lamp, reflected by the mirrors of the pendulums, went beyond the edge of the film. The actual trouble was therefore of an incidental nature. This induced Dr. Vening Meinesz to devise an arrangement for suspending the whole apparatus from a horizontal axis to be placed lengthwise in the ship in order to neutralise the rolling. He supposed that it would be possible to get this constructed at the workshops of the Royal Navy at Gibraltar.

On September 26, between Cape St. Vincent and Cadiz, the sea was very smooth, and for the first time observations were crowned with success, as at a depth of 25 metres the movements were very small. The first observation was made in a place where the sea was 110 metres deep, the second where it was 480 metres deep. During the second observation the direction of the course was taken successively W.E. and E.W., to test the effect of the speed of the ship on the intensity of gravity, first mentioned by Eötvös.

On the afternoon of September 28, Gibraltar was reached, and immediately Dr. Vening Meinesz took steps for the construction of the suspension apparatus. All the assistance desired was kindly given by the British authorities. The time being very limited, it was necessary to carry on the work day and night without intermission.

During the stay at Gibraltar the observations were worked out, and they proved to be very successful. The discrepancies of the observations showed the accuracy to be greater than was expected from the preliminary observations at the Helder. The effect of the speed of the ship was clearly indicated by the diagrams; the speed could even be derived from these with a difference of but $\frac{1}{2}$ mile from the true value.

On October 3, a few hours before leaving Gibraltar, the suspension apparatus was fitted up on board the submarine. I am glad to express thanks to the British authorities at Gibraltar, who so readily contributed to the realisation of Dr. Vening Meinesz's project.

During the passage between Gibraltar and Tunis, the arrangement proved to be satisfactory in every respect. Although the rolling amounted to 2° to each side, observations were easily practicable. A stay at Tunis, where the submarine arrived on October 7, was again used by Dr. Vening Meinesz for the preliminary computation of his observations. One of these gave the value of g for a sea-depth of 2500 metres with a difference of only 0·003 cm. sec.$^{-2}$ from the theoretical value, which indicates complete isostasy.

Tunis was left on October 13, and Alexandria was reached on October 18; the sea being generally very smooth, observations were made without any difficulty. The Eötvös effect was tested again; the deduced speed of the ship differed only 0·3 mile from the true value.

It appears from the diagrams that the accuracy of the deduced period of oscillation in favourable circumstances may be about 1/1,000,000, and that in a rough sea there is little fear of the divergences exceeding 1/100,000. We must wait, however, for the complete computations before a positive statement will be possible.

It should also be mentioned that the rate of the chronometer was controlled by using the rhythmic time-signals of the Eiffel Tower.

On October 31 the squadron, consisting of the mother ship *Pelikaan* and the three submarines, left Suez; it will touch at the ports of Aden, Colombo, and Sabang, and arrive at Batavia about the middle of December. Dr. Vening Meinesz will carry out observations in the Red Sea and the Indian Ocean, and will ultimately determine, with the invar pendulums, the intensity of gravity at a few stations in Java.

From the results already obtained it may be concluded that, by the method of Dr. Vening Meinesz, investigations of the intensity of gravity by pendulum observations can be realised on the parts of the earth covered by the ocean with almost the same accuracy as on continents and islands. For the study of isostasy, and of Wegener's hypothesis of floating continents, observations in submarines, especially between the coast and the deep sea, will be of the greatest value.

J. J. A. MULLER.

Zeist, November 7.

The True Relation of Einstein's to Newton's Equations of Motion.

THE equations of a space-time geodesic or Einstein's general equations of motion of a free particle are, in usual symbols,

$$\frac{d^2x_\iota}{ds^2} + \begin{Bmatrix} \alpha\beta \\ \iota \end{Bmatrix} \frac{dx^\alpha}{ds} \frac{dx_\beta}{ds} = 0, \quad \iota = 1, 2, 3, 4. \qquad (1)$$

In order to show their relation to Newton's equations of motion, which may be written

$$\frac{d^2\xi_i}{dt^2} = \frac{\partial\Omega}{\partial\xi_i}, \quad i = 1, 2, 3, \qquad (N)$$

Einstein considers the special case of slow motion in a weak gravitation field, *i.e.* such that the metrical tensor components $g_{\iota\kappa}$ differ but little from their Galileian values. Then, neglecting squares, etc., of these small differences and also their derivatives with respect to x_4 (quasi-stationary field), Einstein easily obtains the Newtonian equations as a first approximation, with $\Omega = -\frac{1}{2}c^2 g_{44}$ as the classical potential of the gravitation field. This treatment of the question is repeated, so far as I know, by all exponents of Einstein's theory.

Now, as has recently occurred to me, the true relation of Einstein's equations to those of Newton is of a much more intimate nature, and remains valid, no matter how strong the field and how much space deviates from Euclidean behaviour.

In fact, the frame most natural to adopt for an interpretation of the complicated equations of motion (1) of a particle being clearly its own *rest-system*, let x_1, x_2, x_3 be the space-coordinates of the particle in such a system (the latter, of course, to play its part during an infinitesimal time and to be replaced successively by others and others). Moreover, let for convenience the origin of x_1, etc., be taken at the particle itself. Then, at any instant, $x_i = dx_i/ds = 0 (i = 1, 2, 3)$, and equations (1) will reduce to $ds^2 = g_{44}dx_4^2$ and the three equations

$$\frac{d}{dt}\left(\frac{1}{\sqrt{g_{44}}}\frac{dx_i}{dt}\right) = -\frac{c^2}{\sqrt{g_{44}}}\left\{\begin{matrix}44\\ i\end{matrix}\right\}, \quad . \quad . \quad (2)$$

where $dt = dx_4/c$, the fourth equation being already utilised. Now, with i, k reserved for 1, 2, 3,

$$\left\{\begin{matrix}44\\ i\end{matrix}\right\} = g^{ik}\left(\frac{\partial g_{4k}}{\partial x_4} - \frac{1}{2}\frac{\partial g_{44}}{\partial x_k}\right) + \frac{1}{2}g^{i4}\frac{\partial g_{44}}{\partial x_4}.$$

The coordinates can always be chosen so as to make $g^{41} = g^{42} = g^{43} = 0$. This means a frame not spinning relatively to the stars. In these coordinates then, or in such a rest-platform of the particle,

$$\left\{\begin{matrix}44\\ i\end{matrix}\right\} = -\frac{1}{2}g^{ik}\frac{\partial g_{44}}{\partial x_k},$$

and since the x_i can now always be measured along the principal axes of the operator or matrix g^{ik} (when also $g^{ii} = 1/g_{ii}$), we have

$$\left\{\begin{matrix}44\\ i\end{matrix}\right\} = -\frac{1}{2g_{ii}} \cdot \frac{\partial g_{44}}{\partial x_i},$$

no more to be summed over i, of course. These values substituted in (2) give, with $g_{ii} = -a_{ii}$, and since $x_i = dx_i/dt = 0$,

$$\frac{d^2(\sqrt{a_{ii}}x_i)}{dt^2} = -\frac{c^2}{2}\frac{\partial g_{44}}{\sqrt{a_{ii}}\partial x_i}. \quad . \quad . \quad (3)$$

Now, the space-line element of our platform being

$$dl^2 = a_{11}dx_1^2 + a_{22}dx_2^2 + a_{33}dx_3^2,$$

$\sqrt{a_{11}}dx_1$, etc., are the length elements $d\xi_1$, etc., measured along the axes precisely as in (N), and the right-hand member of (3) expresses the gradient of $\Omega = -\frac{1}{2}c^2 g_{44} +$ const. With a proper choice of the constant, $g_{44} = 1 - 2\Omega/c^2$.

We thus see that, *in the rest-system of the free particle, the general relativistic equations* (1) *become identical with the Newtonian equations of motion, rigorously, i.e.* whether the gravitation field is weak or not ($2\Omega/c^2$ a small fraction of unity or not), and no matter how strongly the platform-space differs from a homaloidal or Euclidean space.

This simple investigation is here given not merely because it seems to put the general equations (1) into an interesting and familiar light, but also because it vindicates the rights of the Newtonian equations of motion.

The Influence of Barometric Pressure on the Specific Gravity of the Surface Water in Indian Seas.

IT has for many years been recognised that any alteration in barometric pressure over a wide expanse of water produces concomitant changes in the surface level, and Prof. J. W. Gregory (*Scottish Geographical Magazine*, 1909, vol. xxv. p. 316), when discussing the level of the sea, pointed out that "the sea in an area beneath high air pressure has its surface pushed downwards and the displaced water rises in the adjacent areas." Since the waves of increased barometric pressure occur at approximately the same time of day in each degree of longitude, it follows that each succeeding elevation and depression of the surface level of the sea travels across the ocean like a wave from east to west. In the region of India the barometric pressure normally exhibits in every twenty-four hours a double rise and fall with maxima at approximately 9.45 A.M. and 10.30 P.M. and minima at 3.30 A.M. and 4.30 P.M.

Investigations of the specific gravity (σ_0) of the

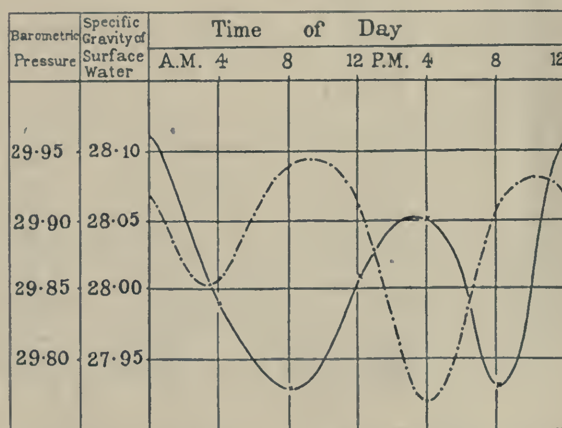

FIG. 1.—Average specific gravity of the surface water and simultaneous barometric pressures during a voyage from Bombay to the Andaman Islands in October 1921.

The continuous line shows the specific gravity, and the dotted line the barometric pressure, in each of the three figures.

surface water of Indian seas have revealed a daily double oscillation that occurs simultaneously with, and must, I think, be due to, the alterations of barometric pressure. This oscillation of specific gravity is, however, only clearly seen in the open sea, because in inshore waters it is obscured by other changes due to tidal flow, etc. During the voyage from Bombay to Port Blair, Andaman Islands, in October 1921, a four-hourly record of the specific gravity of the surface water and the barometric pressure was carefully kept, and the results obtained are shown in Fig. 1. This shows very clearly the way in which, as the barometric pressure falls, the specific gravity of the surface water rises, and vice versa, the two curves alternating with one another.

A variation in the specific gravity of the surface water such as this might be due to (*a*) lateral horizontal movements of masses of water, or (*b*) an upwelling of water from a deeper level. If the latter cause is the true one, then the effect of changes in barometric pressure should be found to depend on the relative specific gravity of the surface water and of water immediately underlying the surface layer. In October, following on the effects of the south-west monsoon, the upper-level water will be diluted and have a lower specific gravity than that immediately below,

and hence an upwelling of deeper water due to a fall in barometric pressure should cause a rise in specific gravity, as seen above.

In Fig. 2, I have given the results obtained in the Bay of Bengal and the Laccadive Sea during the months January and February 1923. It is now found that the oscillation of barometric pressure and specific gravity synchronise with each other. (In this and in Fig. 3, as I have no records made on board

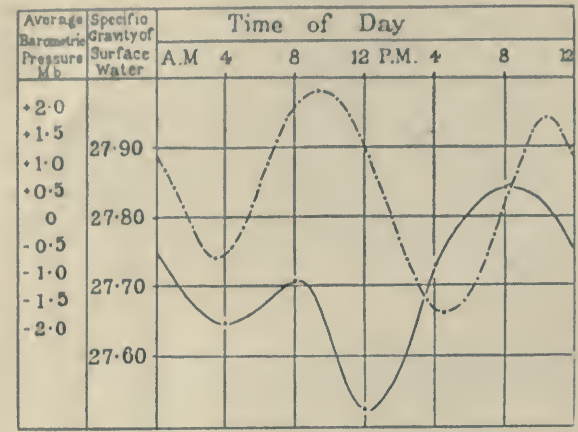

FIG. 2.—Average specific gravity of surface water and average barometric pressure in Indian waters in January and February 1923

ship, I have taken the average barometric pressure registered in Calcutta, as given in the Barometer Manual, 1919.) At this season of the year the rainfall is slight, and, owing to evaporation, the surface layer tends to have a higher specific gravity than water underlying it. In consequence an upwelling of water, owing to lowered barometric pressure, produces a fall in specific gravity.

Finally, in Fig. 3, I have given the results obtained

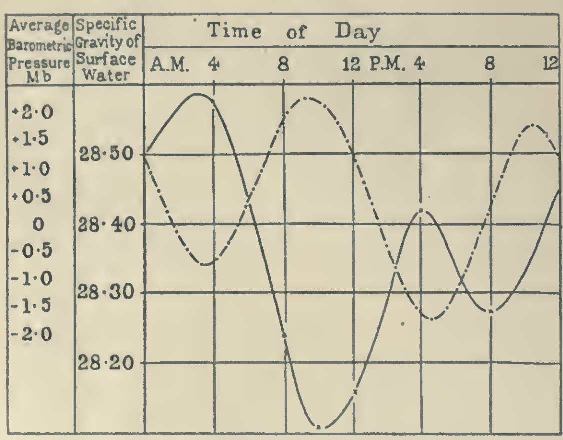

FIG. 3.—Average specific gravity of surface water and average barometric pressure off the west coast of India in May 1923.

off the west coast of India in May 1923. The south-west monsoon had already set in, and there had been a considerable amount of rainfall in the region under investigation since the middle of April. In consequence the surface layer of water had again become diluted, and we now get a return to the condition found in the month of October, *i.e.* a rise of barometric pressure causing a fall in salinity, and a reduction in the pressure being accompanied by a rise due to the upwelling of denser water from below.

Unfortunately, I have no records taken during the month of August, but, judging from the results of the above observations, we should expect to find a fall in barometric pressure accompanied by a rise of specific gravity of surface water, owing to the effect of the monsoon rain in diluting the uppermost levels.

I hope at some future date to be able to publish the full details of my observations, but, as the matter appears to me to be one of considerable interest, I have taken this opportunity of publishing a preliminary note of my results.

Surgeon-Naturalist to the Marine Survey of India.
The Indian Museum, Calcutta.

Spectral Series in the Oxygen Group.

IN the spectrum of oxygen there occur two types of series,—triplet series, and the so-called "singlet" series. The terms associated with the former type are designated by Fowler ("Report on Series in Line Spectra") as *ms*, *mp*, and *md*, while those associated with the latter type are designated as *mS*, *mP*, and *mD*.

One of us (Hopfield) has recently found a number of new oxygen lines occurring in the ultra-violet (NATURE, September 22, p. 437). These appear as fourteen triplets, and for their representation only fifteen different terms are needed. Fourteen of these are previously *known* singlet terms of oxygen ($1S$ to $7S$, $2D$ to $7D$, and $1s$). The fifteenth is a new triplet term, of larger frequency value than any previously known oxygen term. Each of the fourteen triplets represents, on the Bohr theory, the transition from some known singlet energy level to the new triplet level. The nomenclature just given has been used in all previous communications and is identical with that of Fowler, a point apparently not made clear, since the editor of NATURE added a note to the letter of September 22, saying that the S, P, and D terms did not correspond to Fowler's terms of the same designation.

The fourteen oxygen terms include only S (or s) and D terms, and this leads to the conclusion that the new energy level corresponds to a P (or p) term. Whether it is a P or p term is not at once evident. Since the known mp terms of oxygen are triple, while the mP terms are single, the suggestion was made by one of us (Birge) that the new level be designated op_{123}. In fact, the spectral diagrams devised by Brackett and Birge (*Physical Review*, 21, 710, 1923, and Jour. Optical Society of America, now in the press) predict this level at precisely the position found. But it appears, as mentioned in the letter of September 22, that in the op-$1s$ triplet the op_1-$1s$ component is definitely lacking, and a similar phenomenon was later found in the case of the corresponding new sulphur triplets which are discussed in the same communication. Since the $1s$ portion of the op_1-$1s$ designation is known to be correct, and since the known $1s$-mp series of oxygen and of sulphur consist always of triplets, the theory of inner quant numbers leads inevitably to the conclusion that op is *not* the correct designation of the new triple level. Hence the designation has been changed to oP_{123}. An assignment of inner quant numbers to the various terms, according to Sommerfeld's method, then leads immediately to the prohibition of the oP_1-$1s$ component, by the Selective Principle. The inner quant numbers in the case of the triple oP term run in a direction opposite to the usual, in keeping with the "inverted" character

of the new triplets, mentioned in the letter in NATURE of September 22. Again following Sommerfeld (*Ann. d. Physik*, 70, 32, 1923) it is concluded that in the oxygen group the terms labelled by Fowler as mS are single, while the mP terms are triple, and the mD terms quintuple, just as in the case of chromium, which is in the same column of the periodic table. Accordingly the so-called "singlet" series of oxygen are really of a complex nature, a fact that has already been suggested by others (see Fowler, *loc. cit.*, p. 166), while in general the series spectra of the oxygen group are similar to those of chromium, as far as complexity of terms is concerned.

As already noted, similar triplets were found in sulphur, while independently the diagrams by Brackett and Birge had been used to predict the position of most of these new lines, the agreement in all cases being within the limits of error. The diagrams also allow the identification of some ot the other new lines. In particular, the diagrams indicate that the triplets called, in the letter in NATURE of September 22, oP-$3D$ and oP-$4D$ are in reality oP-$2S$ and oP-$3S$ respectively, while those called oP-$2S$ and oP-$3S$ remain unidentified. In addition, the $\lambda 5279$ narrow triplet of sulphur has been identified as $1S$-$2P$. All these points, as well as more general questions, are fully discussed elsewhere by one of us (Birge, "Spectral Series of Divalent Elements," Jour. Optical Society of America, now in the press). One of the conclusions of that paper, derived from a study of the spectral diagrams already mentioned, is that the possible triple levels of the oxygen group, oP and op, while having different sets of inner quant numbers, running in opposite directions, have nevertheless the same average numerical magnitude. But for some unknown reason the oP (valence) level represents a more probable condition, and op does not actually exist. Similarly, in the case of the elements of the second column of the periodic table, the non-appearing os level coincides numerically with the $1S$ valence level.

Identification of Pure Organic Compounds.

IN his review of Mulliken's "Identification of Pure Organic Compounds," vol. iv., on p. 581 of NATURE of October 20, your reviewer surely does the author an injustice. Perhaps he is unacquainted with the earlier volumes, as I am, at present, with the latest—that under review. But I can testify to the great value of volumes i. and ii., and have used them regularly for the last two years. In identifying the components of commercial dyestuffs and similar work, Mulliken's methods are far less troublesome and time-expending than the classical method described by your reviewer, and aptly termed by Mulliken in his preface "the Method of the Empirical Formula." I have never experienced failure in preparing a characteristic derivative by following Mulliken's prescriptions, working with quantities of about $\frac{1}{10}$ gram. In fact, his beautifully neat methods for manipulating small quantities deserve to be more widely known, and, in my opinion, it is a matter for regret that your review will prevent this.

W. A. SILVESTER.

Research Department,
British Dyestuffs Corporation, Ltd.,
Blackley, Manchester.

I WELCOME Mr. Silvester's statement, and am glad to hear that Mulliken's methods are appreciated and found useful in technical organic chemistry. In these matters it is only possible to speak from one's own experience, and, as a research organic chemist and teacher of thirty years' standing, I should not dream of allowing my research students to learn to rely on Mulliken's methods. I adopt this attitude, not because his methods are bad or inaccurate, but because they are incomplete, and an extension of his system to meet all requirements would be impracticable.

J. F. T.

Amanita muscaria on Hampstead Heath.

THE letter from Dr. O. Rosenheim in NATURE of October 27, p. 622, would doubtless cause astonishment to many mycologists. *Amanita muscaria* is one of the commonest toadstools, and is to be found amongst almost any clump of birch trees in this country, consequently being a common sight in woods and on commons near London. The association between fungus and tree, moreover, is so constant that it is not unlikely that the mycelium is one of those concerned in forming birch mycorrhiza.

It is, however, the statement that there is difficulty in obtaining this and presumably other common agarics for scientific investigation that occasions this letter. If any chemist or physiologist desire such specimens, I should be pleased to circulate members of the British Mycological Society to that effect. That common species even are sometimes not to be had has been brought forcibly to my notice during the past two seasons. *Lactarius vellereus* was asked for last year at a time when, normally, the season is on the wane. Though the fungus had appeared in quantity in July and August—the season that year was abnormally early—it was exceedingly scarce in October and November. This year, though many mycologists have been on the look-out for it since the beginning of the season, I have heard of no one finding sufficient to fill a vasculum, let alone the promised hampers; *Amanita mappa*, on the contrary, has been so amazingly abundant everywhere that pantechnicons could have been loaded with it.

It should be emphasised also that toadstools have their due season, the majority appearing some time during the period after summer rains until autumn frosts, and consequently it is not possible to provide fresh material of a given agaric all the year round.

Insecticides.

I AM interested in the question raised in NATURE of October 27, p. 622, as to the efficacy of camphor in preventing moths, and the apparent absence of experimental evidence on the subject. May I suggest that the whole matter of "insecticides" needs investigation. Daily we see upon advertisement hoardings the most alarming pictures, showing the truly devastating effects of popular insecticides on every known and unknown species of the insecta. I have had an opportunity of testing the truth of these statements, and I am profoundly disillusioned.

At the beginning of the rainy season in India my bungalow became in a few days infested with thousands of fleas, which had hatched in the floor matting.

They are smaller than *Pulex irritans* and do not bite so severely. Scores of them marched up my legs as I sat in pyjamas. I bought some tins of that best-known of "insect powders." I covered my legs with it. It had no effect whatever. The fleas bit and jumped with undiminished zest. Before taking steps to rid the bungalow entirely of the creatures, I took a dozen of them, and placed them in an empty biscuit box, and another dozen in a box containing a layer a quarter of an inch thick of the powder. In twenty-four hours the fleas in both boxes were all alive; some were resting actually on the deadly powder. I also shared with many in the trenches the bitter experience that these insect powders had no effect on lice. Ld. de Costobadie.

Mottram, nr. Manchester, November 5.

Lest the good work of American entomologists should be ignored by default, may I direct the attention of your correspondent on the above subject (October 27, p. 622) to two valuable papers recording the results of definite experiments planned against clothes moths? The first, by E. W. Scott, W. S. Abbott, and J. E. Dudley, appeared in 1918 as Bull. 707 of the U.S. Department of Agriculture, "Results of Experiments with Miscellaneous Substances against Bed-bugs, Cockroaches, Clothes Moths, and Carpet Beetles"; the second, "Clothes Moths and their Control," by E. A. Back, appeared in July last as Farmers' Bulletin, No. 1353, of the same Department. These papers contain a mass of information regarding the relative effects and best methods of employing very many different substances against clothes moths belonging to species found in Britain; and curiously enough, in view of the experience of your correspondents, both papers agree in regarding naphthalene in good condition as "one of the safest and best materials for protecting fabrics against moth injury," although it must be used in moderately tight receptacles so that the fabrics remain in a naphthalene-permeated atmosphere. Camphor used in the same way is said to be almost as effective, its fumes killing all stages of clothes moths. James Ritchie.

The Royal Scottish Museum, Edinburgh, November 6.

My own experience of clothes moths in museums extends over many years, and I regret that I cannot agree with "E. E. A." in Nature of October 27, p. 622, that paper is a barrier. The clothes moth "fauna" of Britain is changing. At one time the chief pests were moths belonging to the genus Tinea, which are animal feeders, attacking furs, feathers, wool, silk, etc. To-day the most dangerous pest is *Œcophora* (or *Acompsia*) *pseudospretella*, which, according to Meyrick, was first introduced about 1840. This species eats both animal and vegetable substances. I know it as a disastrous guest of neglected herbaria, preying indifferently on the dried plants or on the paper; and I have observed that it has perforated and penetrated the newspaper coverings of mounted birds and mammals. Fabre, apparently, was unacquainted with this species when he stated that paper is a sure barrier. Pseudospretella certainly prefers slightly damp surroundings, and is known to be a lover of cool climates; it is extremely abundant in London, and is much more conspicuous than any species of Tinea. Perhaps it is not yet established in central or southern France.

Without making any careful experiments, I have believed that naphthalene scattered in cases keeps moths away to some extent. It is not unusual to find a single larva in a store box of mounted insects in circumstances which suggest that the parent has insinuated the egg through a crevice. The larvæ are immune from many well-known insecticides. Fuming with hydrocyanic gas has no effect. The fumes of chloroform cripple the larvæ for a few days; but in a week or so they become active again, and may probably complete their metamorphoses. Drenching with motor spirit is also useless. Larvæ dropped in a strong solution of naphthalene, and then dried until they are thickly encased with a crystal coat, begin to crawl about when the naphthalene is sufficiently evaporated to give freedom of action to the segments. Bisulphide of carbon, in my experience, kills the larvæ.

Bisulphide of carbon, a week or two ago, proved useless in dealing with a small colony of "Museum Beetles"; but drenching the specimen (a mounted bird) with motor spirit appears to have been successful. I take this beetle to be *Ptinus germanus*, described as "scarce" in Cox's "Handbook of Coleoptera," the only work available here at the moment. *Ptinus fur* is the better-known species. Probably the latter insect will require different handling. My own experience of the mites belonging to the genus Glyciphagus is that hydrocyanic gas has no effect, although it is advised by high authority for these disagreeable pests. Like many other "insects," they withstand drenching in petrol, and the only remedy is successive fumings with sulphur dioxide—a plan not always possible in varied collections. A really comprehensive work on museum (and household or warehouse) insects would be very welcome. The losses in stored collections, although for obvious reasons kept secret, are certainly great. This is due not always to neglect, but to the curator's faith in one or other of the well-known insecticides.

I have been told (and certainly credit the tale) that constant vigilance is needed to protect stocks of "Insect Powder" from the ravages of some sort of warehouse pest. Yet this powder, when pure, is very useful indeed in collections, in spite of its comparatively high cost and its messy qualities. Crude experiments on my own part suggest that a mixture of equal parts of borax, sulphur, insect powder, and naphthalene might be scattered or otherwise used as a deterrent. I have tried plunging valuable and delicate specimens such as mounted butterflies and pressed plants, in a solution of celluloid in amyl acetate. When dry, a thin and perfectly invisible "size" of celluloid is left behind. The specimens are thus protected from damp and fungi, and are probably safe from mites also.

An example of the work of Œcophora can here be described. About two years ago a duplicate stuffed wheatear was placed in a glass cupboard, faintly illuminated, and distinctly damp. Three months ago, in clearing out the cupboard, I found that the bird had lost its skin entirely; even the horny rhamnotheca of the beak, and the scales of the feet, had disappeared. Nothing remained except the wires, the bones, and the stuffing; and, strange to say, the stuffing was neither tow nor cotton wool, but waste silk. I have known Œcophora larvæ feeding on a Chinese "joss stick," a compound of resins used as incense, and have found one in an excavation in a "vegetable ivory" nut. In the latter case no other insects were visible, and everything pointed to the moth caterpillar as the culprit.

Fredk. J. Stubbs.

Oldham Corporation Museum.

A Suggested Modification of "Proton" to "Prouton" as a Memorial to William Prout.

THE amazing advances in our knowledge of the composition and structure of matter achieved during the past few decades constitute an important, if not quite final, step toward the establishment of the essential unity of the physical universe.

In reviewing the epoch-making work of J. J. Thomson, whose electrical theory of matter underlies all recent developments in this field, with that of Rutherford, Ramsay, Soddy, Aston, and others in England and elsewhere, one should not be unmindful of the contribution made over a century ago by his compatriot, William Prout, an early apostle of unity.

To all students of chemistry Prout's hypothesis, published in 1816, to the effect that all of the elements are formed from hydrogen by some process of condensation or grouping, has been familiar by reason of the stimulus it has afforded to accurate experimental work. Relegated for many years to the limbo of discarded theories, it has at last emerged to increased plausibility. Although of necessity less specific than the hydrogen-helium theory of Harkins, it is correspondingly simpler, and equally valid if the helium atom, with its four protons and four electrons, be regarded as an intra-atomic polymeride or condensation product of hydrogen. However intricately the more densely populated communities of protons and electrons may be arranged in the heavier atoms, the one proton and one electron of the atom of hydrogen certainly constitute the "first pair" in the chemical Garden of Eden, or present the first stage in the upward evolution of the elements.

In recognition of the genius and insight of William Prout it is suggested herewith that the name "proton" recently assigned to the unit charge of positive electricity, be modified, with some small sacrifice of etymological accuracy, to "prouton," a term with distinctive historical connotation.

ARTHUR WESLEY BROWNE.

Cornell University,
Ithaca, N.Y., U.S.A.

An Uncommon Type of Cloud.

IN NATURE of November 17, p. 725, Dr. Lockyer puts forward a suggestion as to the physics of the formation of "mammato-cumulus" cloud, namely, that it is formed by descent of moist air into colder air below, when there is a reversed vertical temperature gradient, in the same way that "cumulus" clouds are formed by an ascent of warm air (when there is a normal temperature gradient) into colder air above.

Any satisfactory explanation of the formation of this type of cloud would be welcome, but surely "cumulus" clouds are formed by the *adiabatic cooling* when moist air rises to a place where the atmospheric pressure is lower. The general decrease of temperature upwards is only necessary to make such ascent of air possible. A descent of air, such as Dr. Lockyer suggests, must be accompanied by adiabatic warming, since the pressure is increased whatever the general vertical temperature gradient may be. It is true that some cloud might be formed by the mixing which might occur at the surface of separation between two masses of nearly saturated air at different temperatures, but this would not be expected to form the dense globules of cloud actually seen with this type of cloud formation.

G. M. B. DOBSON.

Robinwood, Boar's Hill, Oxford,
November 17.

IN my letter which appeared in NATURE of November 17 I referred to Mr. Arthur Clayden as "the late," when actually he is very much alive. How I came to make this error I cannot understand, but I was most probably thinking of Mr. Clayden as the *late* Principal of the University College, Exeter, and so made the mistake. I much regret the error, and shall be glad if this correction of it can appear in an early issue of NATURE.

WILLIAM J. S. LOCKYER.

Norman Lockyer Observatory,
Sidmouth, S. Devon,
November 20.

National Certificates in Chemistry.

I HAVE observed on page 610 of NATURE for October 27 a reference to the scheme of examinations for national certificates in chemistry.

The writer of the article, upon the basis of an expression of opinion commencing with the word "apparently," proceeds to criticise something on which he is not fully informed. The scheme *is* "designed to secure all the advantages of internal examinations and of reasonable freedom in the arrangement of the courses of work to meet local conditions and needs," and the writer need not fear that there is any truth in the suggestion that before courses of study are recognised they are modified or mutilated by the Board of Education.

So far as national certificates in chemistry and the courses leading thereto are concerned, the Board acts only in conjunction with the Institute of Chemistry.

The experience of the first two examinations for such certificates has amply demonstrated the usefulness of the scheme. No complaint of bureaucratic intervention has been submitted either to the Board or to the Institute.

So far from insisting on "that machine-like uniformity beloved by bureaucrats," the examination papers have, in fact, been set either by the local schools or by their own affiliated groups—such as the Union of Lancashire and Cheshire Institutes.

The view of the writer as to the need of "some measure of central control and to some sound and official organisation" is incontestable: those desiderata are precisely those which the scheme is designed to attain.

RICHARD B. PILCHER,
Registrar and Secretary.

Institute of Chemistry,
30 Russell Square, London, W.C.1,
November 13.

MR. PILCHER will know that before an educational institution can submit candidates for national certificates the course of study proposed must be approved by the Board. This, of course, is absolutely necessary and desirable, but it is at this stage that modifications may be suggested by the Board—the alternative to acceptance being refusal to place the institution concerned on the approved list. I do not suppose for one moment that modifications of courses proposed are not necessary sometimes, but I do suggest that the trend of the modifications is towards uniformity of syllabuses.

I have no suggestions to make, at present, on the actual conduct of the examinations, and I know that the papers are set by the local schools and assessed by gentlemen whose work is not questioned. My reference was made distinctly to the pre-recognition stage, and I can assure Mr. Pilcher that I did not write without some knowledge.

I would also point out that I was referring to complete courses of work—including subjects ancillary to the main subject, and covering a period of from three to five years.

THE WRITER OF THE ARTICLE.

Zoological Bibliography.

REFERRING to my letter on this subject in NATURE of November 3, p. 652, I am asked to state that the recommendation that the size of the publications of scientific societies should, if possible, be demy octavo, originated with a committee of the British Association on the size of periodicals, not with that on Zoological Bibliography and Publication; and that this was also the recommendation of the Corresponding Societies' Committee at Liverpool.

T. SHEPPARD.

The Museums, Hull.

THE British Association Committee on Zoological Bibliography and Publication desires me to emend a statement in the friendly and welcome letter which Mr. T. Sheppard has addressed to you on behalf of the Corresponding Societies' Committee (NATURE, November 3, p. 652). The recommendation that the format of a society's publication should be demy octavo (approximately, $9 \times 5\frac{3}{4}$ in., or $22{\cdot}5 \times 14{\cdot}5$ cm.) does not occur in the last report of my Committee or in any of its previous reports.

If that recommendation was made either by the Corresponding Societies' Committee or by the Conference of Delegates from those societies, it will doubtless have been transmitted to the Council of the British Association, and will presumably be communicated by that body to the Committee which it has appointed to report on such questions.

Meanwhile I am to add that my Committee already has a different proposal of the same nature laid before it, and that it will report on the subject in due course.

The only recommendation by the Conference of Delegates of which I have received information is as follows: "To urge the adoption by scientific societies of the bibliographical recommendations contained in the current Report of the Zoological Publications Committee."

May I request those who may desire a copy of the Committee's last report to address themselves to me at the Natural History Museum, London, S.W.7, and not to the Secretary of the British Association.

F. A. BATHER,
Secretary.

November 12.

A Standard System for Scientific and Technical Publications.

THE enormous amount of current scientific and technical literature is a matter of common remark. It goes to swell an ever-increasing accumulation, of which a large portion, comprising research data, observations, measurements of values, and so forth, remains of permanent value. The various published indexes serve to keep account of it, but the labour required to make a comprehensive review over any range of recorded fact is considerable, and will steadily increase as time goes on. With the view of alleviating such labour I have worked out in detail an organised publication system, as specified below in two parts.

1. *The Standard Page Size Scheme.*—A certain suitable size should be nominated as the standard page size, and be adopted generally for scientific and technical publications, except for special reason to the contrary. The size would be chosen by experts, and would be some compromise between a small magazine size and a book size.

2. *The General Encyclopædia Scheme.*—Standard size publications of booklet and pamphlet form to be perforated at a standard spacing for filing on the ring-book, or other similar system. Each of such publications to have a word or phrase, descriptive of the contents, printed on the top right-hand corner of the front page, so that by this "cyclopædic phrase" such publications can be filed in alphabetical order. In the case of periodicals, each important article should begin at a right-hand page, and occupy a whole sheet or set of sheets, the space left over being left blank, or filled with advertisements or small matter. The periodicals should be so bound that such articles can be withdrawn without mutilation; the standard perforation and cyclopædic phrases should be provided as for pamphlets.

Upon the adoption of the system, pamphlets and articles withdrawn from periodicals would be filed in an orderly and compact collection in covers of book size, in alphabetical order, or order of classification as desired. But I specially argue that the system would permit of a variety of arrangements of great service to those who desire to make any review over recorded fact. Only certain classes of periodicals need conform to the system, in order to derive the main advantages of it, and existing indexing arrangements need not be upset by it.

The above will give only the roughest idea of the system; it has many modifications, and there are very many considerations to be taken into account. But I am prepared to go into precise details with any committee set up to consider the system from a general scientific point of view. Such a committee might, for example, be appointed by the British Association. I shall also be glad to supply an account of the system to any person specially interested.

A Fossil Caddis-case.

ATTENTION has frequently been directed of late to the extraordinary persistence in time of various insect structures, as shown by fossils. It might be assumed that the reactions and instincts of insects were similarly ancient, and of this we have a certain amount of actual proof, as in the case of some of the ants, the remains of which are so abundantly preserved in Baltic amber. When I was recently in Vladivostok, Dr. A. Kryshtofovich showed me some curious insect cases found fossil in the Tertiary rocks at Posiet, a locality in Siberia close to the border of Korea. One of these cases, which he gave me, proves on examination to be that of a caddis-fly of the genus Phryganea, quite similar to the modern *Phryganea grandis*. It is composed of pieces of *Sequoia langsdorfii*, which are arranged side by side in the usual spiral fashion, and are about 5 mm. long and 1·2 mm. wide, the case itself being 7 mm. wide. The species represented by these cases may be called *Phryganea Kryshtofovichi* n. sp. (Fig. 1). The cases from the Miocene of Oeningen in Baden, long ago named *Phryganea antiqua* by Heer, do not belong to this genus. The true Phryganea case is quite a specialised structure, with a definite spiral arrangement, which we now see to have been evolved long ago, the Posiet beds being Lower Miocene or probably earlier. In the insect-bearing beds on the Kudia River, Siberia, N. lat. 46°, I secured a wing of Phryganea, which will be described elsewhere.

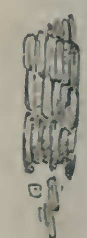

FIG. 1. — *Phryganea Kryshtofovichi* case.

Hormones.[1]

By Prof. E. H. Starling, C.M.G., F.R.S.

In the dedication to his work, Harvey compares the heart to the sovereign king, and throughout he continually recurs to what we should now describe as the "integrative function" of this organ. In virtue of the circulation which it maintains, all parts of the body are bathed in a common medium from which each cell can pick up whatever it requires for its needs, while giving off in return the products of its activity. In this way each cell works for all others—the lungs supply every part with oxygen and turn out the carbon dioxide which it produces, the alimentary canal digests and absorbs for all, while the kidneys are the common means of excretion of the soluble waste products of the body. Changes in any one organ may therefore affect the nutrition and function of all other organs, which are thus all members one of another. But, in addition to enabling this community of goods, the circulation affords opportunity for a more private intercourse between two or at any rate a limited number of distant organs.

It is now eighteen years since I directed attention to the chemical messengers or hormones which are employed by the body for this purpose. As an illustration of the method by which they work, I adduced the example of carbonic acid gas, which is the product of all cellular activity and at the same time has a specific excitatory effect on the respiratory centre, so that the respiratory movements keep pace with the needs of the whole body for oxygen. The typical hormone, however, is a drug-like body of definite chemical composition, which in a few cases is actually known, so that the substance has been synthesised outside the body. It is more or less diffusible, and may even withstand without alteration the temperature of boiling water. It is generally easily oxidisable in a neutral or alkaline medium, so that after its production it does not remain long in the blood; it delivers its message and is then destroyed. Each specific hormone is manufactured by a group of cells and turned into the blood, in which it travels to all parts of the body, but excites definite reactions in one or a limited number of distant organs. The production and action of these substances are continually going on in the normal animal. They are necessary to health, and their production in excess or in deficit gives rise to disease and maybe to death.

Typical of all hormones is secretin, a substance produced in the epithelial cells lining the upper part of the small intestine when these come in contact with weak acid, so that it is set free in normal circumstances by the passage of the acid chyme from the stomach into the duodenum. Directly it is produced it is absorbed into the blood and travels round to the pancreas, to the liver, and to the intestinal glands, in all of which it excites secretion. By means of this chemical reflex the arrival of the products of gastric digestion in the small intestine evokes within a couple of minutes the secretion of the three juices the co-operation of which is necessary for completing the work of digestion and solution of the food, already begun in the stomach. It is probable that this mechanism is but one of a whole chain of chemical reflexes responsible for the orderly progression of the various stages in the digestion of food.

These hormones may apparently be formed by any kind of tissue. In many cases a gland which has, in the evolutionary history of the race, poured its secretion by a duct into the alimentary canal or on to the exterior, loses its duct and becomes a ductless gland, the secretion being now transferred either immediately or through the lymphatics into the blood stream. In either case these chemical messengers may be formed from masses of cells which have at no time had a glandular structure and may be modified nervous tissue, germinal tissue, or some part of the mesoblast.

As a type of the ductless gland derived from one with an external secretion the most familiar example is the thyroid. The physiological action of its internal secretion and the morbid results of its excess or deficiency, affecting tissue growth and development, metabolism, and mentality, are familiar to all. In recent years the active substance has been actually isolated, and its constitution determined, by Kendal, who has shown that it is an iodine derivative of an amino-acid, tryptophane. It seems almost a fairy tale that such widespread results, affecting every aspect of a man's life, should be conditioned by the presence or absence in the body of infinitesimal quantities of a substance which by its formula does not seem to stand out from the thousands of other substances with which organic chemistry has made us familiar.

Although we do not yet know their constitution, the chemical messengers associated with the reproductive organs are possibly even more marvellous in the influence they exert on the different parts and functions of the body. The effects of castration have been the subject of observation almost from the beginnings of civilisation, but it is only during the last few years that definite proof has been brought forward showing that these effects are due to the removal of chemical messengers normally produced in the testes. The whole differentiation of sex, and the formation of secondary sexual characters, are determined by the circulation in the blood of chemical substances produced either in the germ cells themselves or, as seems more probable, in the interstitial cells of the testis and ovary, which themselves are probably derived from the germ cells of the embryo. Thus it is possible by operating at an early age to transfer male into female and *vice versa*. Removal of the ovaries from a hen causes the assumption of male plumage; the removal from a young cock of the testes and their replacement by the implantation of ovaries cause a disappearance of the comb and the assumption of the plumage of the hen. Each animal as concerns its general build and colour has a neutral form which, as has been shown by Pézard, results from the extirpation of either testes or ovaries. In fowls the neutral form, as judged by the plumage, approximates the male, whereas in sheep the neutral form resembles the female. There is no question that, by the

[1] From the Harveian Oration, entitled "The Wisdom of the Body," delivered before the Royal College of Physicians of London on St. Luke's Day, October 18.

implantation of ovaries or testes into the fœtus at a sufficiently early age, one could produce the whole development of the internal and external genitalia corresponding to the sex of the gland implanted.

It is worthy of note that these sex characters affect also the mentality and the reactions of the animal, although they are quite independent of any nervous connexions. Here, as in the case of the thyroid, the functions of the central nervous system in their highest manifestations depend on the circulation in the blood of chemical substances or hormones. The wonderful development that takes place in the female after conception to fit her to nourish the fœtus as well as the young child, is also due to hormones, produced in some cases perhaps in the ovaries, in other cases in the product of conception itself.

We owe to Schafer the knowledge of the internal secretion of the medulla of the suprarenal bodies. As Cannon has pointed out, this secretion is poured into the blood during conditions of stress, anger, or fear, and acts as a potent reinforcement to the energies of the body. It increases the tone of the blood vessels, as well as the power of the heart's contraction, while it mobilises the sugar bound up in the liver, so that the muscles may be supplied with the most readily available source of energy in the struggle to which these emotional states are the essential precursors or concomitants.

Wonderful, too, is the influence exerted by the secretions of the pituitary body. This tiny organ, which was formerly imagined to furnish the mucus to the nasal cavities, consists of two lobes which have different internal secretions. That produced by the anterior lobe seems to influence growth, excess producing gigantism or acromegaly, while deficiency leads to retarded growth and infantilism. The posterior lobe, which in aspect would seem but a small collection of neuroglia, nevertheless forms one or more substances which, circulating in the blood, have the most diverse influences on various parts of the body. They cause contraction of the uterus and of the blood-vessels (these are possibly two distinct substances); they may increase or diminish the flow of urine; they affect the excretion of chlorides by the kidney; and, according to Krogh, their constant presence in the blood is essential for maintaining the normal tone of the capillaries. In the frog the post-pituitary hormone is responsible for the protective adaptation of the colour of the skin to the environment, an adaptation which is effected by retraction or expansion of the pigment cells or chromatophores of the skin; and, if we may accept Kammerer's conclusions, the pituitary hormone which is poured into the blood for this purpose affects the germ cells themselves, so that individuals born of parents that have lived in light or dark surroundings are correspondingly light or dark—a real transmission of acquired peculiarities, effected not by the gemmules of Darwin, but by the influence of a soluble diffusible hormone on the germ plasm.

In the multiplicity and diversity of the physiological effects produced by these various chemical messengers, one is apt to lose sight of the fact that we are here investigating one of the fundamental means for the integration of the functions of the body. These are not merely interesting facts which form a pretty story, but they are pregnant of possibilities for our control of the processes of the body and therewith for our mastery of disease. Already medical science can boast of notable achievements in this direction. The conversion of a stunted, pot-bellied, slavering cretin into a pretty, attractive child by the administration of thyroid, and the restoration of normal health and personality to a sufferer from Graves's disease by the removal of the excess of thyroid gland, must always impress us as almost miraculous. In the same way we may cure or control for the time being diabetes insipidus by the injection of the watery extract of the posterior lobe of the pituitary body. The latest achievement in this direction is the preparation by Banting and Best in Canada of the active principle normally formed in the islets of the pancreas, and the proof that the diabetic condition in its severest forms can be relieved by its subcutaneous administration.

In my Croonian Lectures I asserted that, if a mutual control of the different functions of the body be largely determined by the production of definite chemical substances in the body, the discovery of the nature of these substances will enable us to interpose at any desired phase in these functions, and so to acquire an absolute control over the workings of the human body. I think I may claim that, in the eighteen years that have since elapsed, we have made considerable progress towards the realisation of this power of control which is the goal of medical science. But there still remain much to be done and many difficulties to be unravelled, and it may be worth our while to consider along what lines researches to this end must be directed.

There are no doubt many hormonic relationships of which at present we are unaware, since every year research adds to their number. But assuming we know that such and such an organ produces an internal secretion which is necessary for the normal carrying on of a given function or functions, we may desire to diminish or enhance its effects in a patient or to replace it when it seems to be entirely lacking. There seem to be three possible methods by which we medical men can interpose our art in the hormonic workings of the body.

(1) In the first place, we may find what is the effective stimulus to the production of the hormone, and, by supplying this, increase its production by the responsible cells. For example, we know that by the administration of acid, or at any rate by increasing the passage of weak acid from the stomach to the duodenum, we can enhance the production of secretin and so of pancreatic juice and the other juices. Probably, therefore, when we give dilute acids to assist gastric digestion we are setting into motion the whole chain of reflex processes in the alimentary canal, and the chief value of our administration may be its effect on the pancreas. But in a large number of cases we do not yet know what is the effective stimulus to the production of these internal secretions. In the case of the adrenals we know the secretion can be augmented through the central nervous system and the splanchnic nerve under the influence of emotions or of lack of oxygen, but we have no knowledge of the factors determining the production of the pituitary hormones or of insulin by the islets of Langerhans, and this

condition of ignorance extends to most of the other ductless glands.

In some cases deficient production of a hormone may be due to the absence from the food and drink of some necessary constituent. Thus iodine is essential to the formation of the specific secretion of the thyroid gland (iodothyrin). If iodine be entirely absent from the drinking water and the soil, so that it is not contained even in minute quantities in the vegetable food grown in the district, the thyroid undergoes hyperplasia—in vain an endeavour to make bricks without straw, to produce its proper hormone without iodine. This seems to be the cause of the great prevalence of simple goitre in certain districts—especially in Switzerland and in parts of the United States. It has been shown that goitre can be practically eliminated from these districts by the occasional administration of small doses of iodine or iodides (Marine, Lenhart, Kimbull, and Rogoff). These results were communicated in 1917 to Dr. Klinger of Zürich, and as a result of his experience the Swiss Goitre Commission has recommended the adoption of this method of goitre prevention as a public health measure throughout the entire State. Already great progress has been made in the abolition of this disease from the country. Thus the incidence of goitre among all the school children of the canton of St. Gallen has been reduced from 87·6 per cent. in January 1919, to 13·1 per cent. in January 1922.

(2) Where a disordered condition is due to diminished production of some specific hormone we may extract the hormone from the corresponding gland or tissue in animals. It is characteristic of these hormones that, so far as we know, they are identical throughout all the classes of vertebrates, and it is possible that they may be found far back in the invertebrate world. This method is easy when, as in the case of the thyroid, the active principle is stored up in the gland and is unaltered by the processes of digestion, so that we can obtain all the curative effects of the hormone if we administer dried thyroid by the mouth. We have no evidence that any other of the hormones with which we are acquainted partake of this resistance to digestion, so that to produce their specific effects they have to be introduced by subcutaneous injection —a great drawback when the administration has to provide for the constant presence of a small concentration of the hormone in the blood and tissues. In the case of insulin, for example, it seems necessary to repeat the injection every twelve hours to obtain any continuity of action, and the same thing probably applies to the pituitary extract, while in the case of the genital hormones no trustworthy effect has been obtained except by the actual implantation of the organ from an animal of the same family.[2]

[2] In my Croonian Lectures in 1905 I reported some experiments made in conjunction with Dr. Lane-Claypon, in which I had produced hypertrophy of the mammary glands in virgin rabbits, and in some cases actual secretion of milk, by the daily subcutaneous injection of the filtered watery extract of young rabbit fœtuses. Similar results were obtained by Foà. But a weak point in these experiments was that the ovaries had not been previously extirpated. Ancel and Bouin have shown that in the rabbit the mere rupture and discharge of a Graafian follicle, with the subsequent growth of a corpus luteum, are sufficient to cause hypertrophy of the mammary glands (the effective hormone presumably having its seat of manufacture in the luteal cells). It seems possible, therefore, that the effect of our injections may have been on the ovaries, and that the growth of the mammary glands was only a secondary and indirect result. I do not therefore now regard our experiments as conclusive.

We may, however, look forward to the day when the chemical constitution of all these hormones will be known, and when it may be possible to synthesise them in any desired quantity. We may then be able to overcome the inconvenience of subcutaneous injection by giving relatively colossal doses by the mouth, or we may be able to modify their constitution to a slight extent so as to render them immune to the action of digesting fluids, without affecting their specific action on the functions of the body.

(3) The ideal, but not, I venture to assert, the unattainable, method will be to control, by promotion or suppression, the growth of those cells, the function of which is to form these specific hormones. Though this method seems at present far from realisation, the first steps in this direction have already been taken. It must be remembered that the power of controlling growth of cells involves the solution of the problem of cancer. Here the experiments on the growth of normal cells outside the body have shown that they can be stimulated to vie with cancer cells in the rate of their growth, or can be inhibited altogether according to the nature of the chemical substances with which they are supplied. We know that the growth of certain cells, such as those of the mammary gland or of the uterus, is excited by specific chemical substances produced in the ovary or fœtus; and we may be able to find specific substances or conditions for any tissue of the body which may excite growth which is retarded, or diminish growth when this is in excess.

It may be that in some cases purely mechanical interference will suffice. Thus in experiments by Steinach and others it has been found that ligature of the vas deferens close to the testis, while causing atrophy of the seminiferous cells, brings about overgrowth of the interstitial cells, which, as we have seen, are chiefly responsible for the hormones determining the secondary sexual characters. Among these secondary sexual characters must be classed the whole of a man's energies. Virility does not mean simply the power of propagation, but connotes the whole part played by a man in his work within the community. As a result of this hypertrophy these authors claim to have produced an actual rejuvenation in man, and thus to have warded off for a time senility with its mental and corporeal manifestations. Further experiments and a longer period of observation are necessary before we can accept these results without reserve, but it must be owned that they are perfectly reasonable and follow, as a logical sequence, many years' observations and experiments in this field.

It would indeed be an advantage if we could postpone the slowly increasing incapacity which affects us all after a certain age has been passed. Pleasant as it would be to ourselves, it would be still more valuable to an old community such as ours, where the arrival of men in places of rule and responsibility coincides frequently with the epoch at which their powers are beginning to decline. The ideal condition would be one in which the senile changes affected all parts of the body simultaneously, so that the individual died apparently in the height of his powers. For it must not be thought that in any such way we could prolong life indefinitely. Pearl has pointed out that

if all the ordinary causes of premature death were eliminated, this would increase the average duration of life by not more than thirteen years. On the other hand, he shows that the children of long-lived parents have an expectation of life which is twenty years greater than that of the average individual.

It is evident, then, that if longevity is our goal it is not medical science we must look to but eugenics, and I doubt whether the question is one with which we are concerned. The sorrow of the world is not the eternal sleep that comes to every one at the end of his allotted span of years, when man rests from his labours. It is the pain, mental and physical, associated with sickness and disability, or the cutting off of a man by disease in the prime of life, when he should have had many years of work before him. To us falls the task of alleviating and preventing this sorrow. In our childhood most of us learnt that suffering and death came into the world through sin. Now, when as physicians we stand on the other side of good and evil, we know that the sin for which man is continuously paying the penalty is not necessarily failure to comply with some one or other of the rough tribal adjustments to the environment, which we call morality, but is always and in every case ignorance or disregard of the immutable working of the forces of Nature, which is being continually revealed to us by scientific investigation.

In spite of the marvellous increase in knowledge, to some aspects of which I have directed your attention, suffering is still widespread amongst us. Only by following out the injunction of our great predecessor —to search out and study the secrets of Nature by way of experiment—can we hope to attain to a comprehension of "the wisdom of the body and of the understanding of the heart," and thereby to the mastery of disease and pain which will enable us to relieve the burden of mankind.

The Equation of Van der Waals.[1]

By J. H. JEANS, Sec. R.S.

VAN DER WAALS' equation

$$\left(p+\frac{a}{v^2}\right)(v-b)=aT$$

expresses the result of supposing a molecule to be endowed with two distinct physical properties—finite size, giving rise to the term b, and cohesive force, giving rise to the term a/v^2. The physical meaning of the equation is best exhibited by drawing diagrams of isothermals of the familiar type. Representing different gases there will be different diagrams corresponding to different values of a and b. It is, however, readily shown that one diagram of this type can be made to represent all values of a and b, and so the isothermals of all gases, by suitable expansions and contractions of its horizontal and vertical scales. On removing the scale from any single diagram we have a universal diagram which represents the p, v, T relation for all gases, but without specifying the scale. The circumstance that such a diagram is possible is equivalent to the so-called "Law of Corresponding States"; this is now seen to be a mathematical consequence of Van der Waals having confined himself to a two-constant specification of molecular structure.

Thus the accuracy, or the reverse, of the law of corresponding states provides a test of the sufficiency of Van der Waals' two-constant specification of a molecule. In actual fact the law is not very closely obeyed; the deviations show distinct correlation with atomicity, and so suggest that the two-constant specification is not altogether adequate—a full treatment must take account of differences of atomicity (or physical shape) as well as of differences of size and cohesive power.

Van der Waals explained his cohesive power by the supposition that all matter possesses inherent powers of attraction for all other matter. Gravitational attraction is numerically far too small to come into the question at all, so that it is to the electrical structure of matter that we must look for the origin of this supposed universal attraction.

If molecules were electrically charged structures, similar molecules would repel one another; as they are electrically neutral, they will repel in some orientations and attract in others, but two molecules meeting at random are as likely to repel as to attract. It is only when the *duration* of molecular encounters is studied that we find an explanation of the preponderance of attraction over repulsion—attractive encounters draw the molecules farther and farther into each other's sphere of influence, and so last longer than repulsive encounters. Comparing the two types of encounters, the "birth rate" is the same for each, but the "expectation of life" is longer for attractive encounters, so that for the encounters in being at a specified instant, there is a preponderance of attractive encounters, and hence a resultant attractive force. This attractive force, however, originates far more in an abstruse theorem of statistical mechanics and far less in an inherent property of matter, than Van der Waals supposed.

If this interpretation is right, the cohesive forces must disappear at very high temperatures and must steadily increase with decreasing temperatures, so that a must be a function of the temperature and not, as Van der Waals supposed, a constant. In point of fact, all attempts to bring Van der Waals' equation into closer agreement with observation begin by making a a function of the temperature. Moreover, a is found to vanish at infinite temperatures in conformity with the suggested explanation.

The second constant b was supposed by Van der Waals to have its origin in the finite sizes of the molecules. If, for example, the hydrogen molecule is regarded as a sphere, its radius as calculated from the observed value of b is found to be $0{\cdot}64\times10^{-8}$ cm. The same radius can be calculated independently in other ways; the coefficients of viscosity, of conduction of heat and of self-diffusion all agree in yielding the value $0{\cdot}68\times10^{-8}$ cm. The average of these, $0{\cdot}66\times10^{-8}$ cm.,

[1] Synopsis of part of the Van der Waals Memorial Lecture delivered before the Chemical Society on November 8.

would give for the hydrogen *atom* a volume equal to that of a sphere of radius $0{\cdot}53 \times 10^{-8}$ cm. But the normal hydrogen atom, as is now known from the researches of Bohr, consists of two electric charges, describing a circular orbit, one about the other, of radius precisely equal to $0{\cdot}53 \times 10^{-8}$ cm. As regards collisions with other molecules, this invertebrate structure, consisting of two point-charges with no material connexion between them, appears to reserve for itself a three-dimensional spherical volume with as much precision as though it were a sphere of infinite hardness.

The explanation of this infinite hardness is to be found in the intangible fetters of the quantum dynamics. The nature of these fetters is not in the least understood, but it is believed that they are such that no force in creation can cause the electron of the hydrogen atom to describe a smaller orbit than the normal orbit of radius $0{\cdot}53 \times 10^{-8}$ cm. If it is further supposed that this orbit is free to assume all orientations in space we begin to understand why it is legitimate, for kinetic theory purposes, to treat the hydrogen atom as an infinitely hard sphere of radius $0{\cdot}53 \times 10^{-8}$ cm. The quantum theory brings us back, in a sense, to the infinitely hard spherical atoms of Lucretius, and the radius of these spherical atoms can now be calculated with precision from the quantum theory; their infinite hardness is beautifully exemplified in the experiments of Franck and Hertz.

It is thus seen that the *a* and *b* of Van der Waals admit of exact interpretation in terms of the physical conceptions of to-day. His *b* arises from what we may call the quantum forces—the perfectly unyielding restraints which bind the electrons of an atom down to definite orbits—while his *a* arises from the ordinary electric field of force. It is the *b* of Van der Waals which saves us from immediate annihilation, through positive and negative charges rushing together to their mutual destruction, just as it is his *a* which saves us from rapid disintegration.

The Nerves of Plants.[1]

By Prof. Henry H. Dixon, F.R.S.

The general similarity of the distribution of the fibro-vascular bundles in plants and that of the nerves in animals was early noticed. These structures in plants were in consequence often called nerves. However, anatomists and physiologists alike have long held the view that the likeness is merely superficial, and is not based on any real physiological or anatomical resemblance.

In plants—as in animals—the receptive and responsive regions are often quite distinct from one another, and may be widely separated. What becomes of the stimulus between the two, and how is it transmitted? Remarkable experiments during the last ten years have given the answers to these questions.

First may be summarised, in a few words, Ricca's work on the sensitive plant, Mimosa. The phenomena of transmission of stimuli in this plant are as striking as they are well known. The stimulus is propagated through its organs at velocities variously estimated at 10-20 mm. per sec. This speed is fast among plants, but very slow when compared with the velocity of transmission of stimuli along animal nerves.

Two views were suggested to account for this propagation. The first referred the passage of the stimuli to those excessively fine strands of protoplasm which, penetrating the walls of the living cells, place the protoplasts of adjacent cells in communication with one another. This view was a product of a period obsessed with the physiological importance of these then recently discovered protoplasmic fibrillæ, which, in all probability, have only a developmental significance. These fibrillæ composed of living matter were supposed to convey stimuli just as the living processes of the nerve cells do in the animal body.

This view was soon rendered untenable when it was shown that stimuli are effectively transmitted even after the protoplasm of the cells of the transmitting organs was killed by the application of heat.

To meet this new growth of knowledge Haberlandt developed his theory, that the stimuli are transmitted in Mimosa in the form of a pulse in the water filling certain elongated tubular cells situated in the bast of the bundles. At the best this was an unsatisfactory theory. For this method would require a much higher velocity of transmission than is observed, and it was wellnigh impossible to imagine how the turgor requisite to transmit this pulse could be maintained after the protoplasts of these tubes had been rendered permeable by heat.

In 1914 Ricca gave the *coup de grâce* to the pulse theory. He showed that the stimulus is transmitted through a strand of Mimosa wood from which all the bast, including the tubes of supposed transmitting function, had been removed for a considerable length. By a series of beautiful experiments Ricca showed that the wood, as Dutrochet long ago believed, transmits the stimulus, and that it does this even when all its living elements are eliminated. Further, he demonstrated that the mechanism of the transport is the transpiration current. This carries in its stream a substance, or hormone, originating from the receptive cells, to the cells of the reactive region and so evokes their response. Ricca's work also disposes of a more recent view that the stimulus is transmitted as an electrical disturbance in the bast.

Almost at the same time as Ricca was disposing of the older views regarding the transmission of stimuli in Mimosa, Boysen-Jensen was carrying out experiments on the phototropic reactions of seedlings, which were bound to have a profound effect on the received views regarding the propagation of stimuli.

When the tip of a grass-seedling is illuminated on one side a stimulus is transmitted from the receptive region downwards in the seedling and evokes a curvature in the shaded part. Boysen-Jensen found that this stimulus was transmitted downwards even when the protoplasmic continuity of the cells of the receptive apex with those of the responsive region was severed by complete section.

[1] Synopsis of a lecture delivered before the Royal Dublin Society on November 9.

Paál repeated and confirmed Boysen-Jensen's results and added the important observation that the stimulus can pass a slice of pith 0·1 mm. thick impregnated with gelatin intercalated between the receptive and responsive regions. Similar work has been since carried out by Stark on thigmotropic and traumatotropic stimuli. This experimenter brought to light the fact that the receptive tip of one plant may be transferred to the base of another and after stimulation may determine curvature in the latter. Furthermore, the certainty of this response to thigmotropic stimuli depends, other things being equal, upon the phylogenetic affinity of the two parts. Recently Snow has shown that the gravitational stimulus is transmitted across protoplasmic discontinuities in the seedlings of *Vicia faba*.

From the foregoing it is quite evident that protoplasmic continuity is not requisite for the transmission of stimuli in the higher plants. The localisation of the positive and negative responses respectively to one side of the reacting region and the velocity of transmission will not allow us to assign the propagation to simple diffusion; but these characteristics point clearly to the transpiration-stream. It affords the localised delivery and the necessary velocity. Introduction of the requisite hormones may be effected through uninjured cells, or along moist wound surfaces. This consideration explains how it is that continuity between the vascular bundles of the receptive tip and those of the responsive base is not necessary to secure the reaction. Thus, there is great probability that in these plants, as in Mimosa, the transmission of stimuli is effected by the transport in the transpiration-stream of a substance derived from the receptive cells, and conveyed by this means in the wood of the vascular bundles to the responsive region. We may imagine that this substance is first liberated into the transpiration stream by changes in the permeability of the receptive cells, and response is evoked in the reactive cells by similar alterations in permeability.

Whatever the intimate mechanism of the system is, the subject of the transmission of stimuli through plant tissues offers a striking example of the swing of the pendulum of scientific opinion. The view based upon superficial resemblances, that the vascular bundles are the nerves of plants, was long abandoned, but now we see there is clear evidence that they actually transmit stimuli from the sensory to the motor regions, and so perform the function of nerves. The foregoing summary of recent work indicates how differently in detail this connexion is established in plants and animals.

Obituary.

MRS. HERTHA AYRTON.

APPEAL is made to me to give some account of Hertha Ayrton, the wife of my former colleague, who died last August.

"Is the study of heredity a science or a pure romance?" asks Mrs. Trevelyan, in her biography of her mother, Mrs. Humphry Ward. I would set the question in another form: Is *das ewig Weibliche* to be suppressed by science? Mrs. Ayrton was one of those who aspired to prove that woman can be as man as an original scientific inquirer. Did she succeed? If we are to frame a psychology of the scientific mind, regarding this as a species apart, we must carefully note and analyse the doings of such as she. I have but small qualification for the office, yet as she was my colleague's wife and we often met and were in fair sympathy, I was able to take notice of her idiosyncrasies and of the conditions under which she was placed.

Ayrton and I met originally in the autumn of 1879, when we were appointed the first two professors of the City and Guilds Institute and set the ball of technical education rolling in London; the ball rolled well and proved to be fissiparous but no one of the small band who gave it shape in the City and West End ever received the slightest recognition from the Guilds, their masters—and most of these have committed *hari-kari* as concerted workers in education. A strange world is ours and if we worked otherwise than for the sake of working, we should do little.

Ayrton had a peculiar experience: his then (first) wife—his cousin, Mathilda Chaplin—was a woman who had acquired merit in the cause of women's rights, as she was one of the three, I believe, over whom the fight first raged in Edinburgh whether women should be admitted to the study of medicine. When I met her, her health was more than failing. She was an ethereal being, a woman of infinite charm of manner but above the world—a mature Melisande; indeed, when I first heard Debussy's opera her memory was recalled to me by the peculiar rhythm and tone of its melody. Her daughter, Mrs. Zangwill, has inherited not a few of her mother's characteristics—especially her charm of voice. Her chief occupation was novel-reading, from penny-dreadfuls upwards, in which she ran a caucus race with our erratic friend, John Perry.

Ayrton married his second wife in 1885. If I were to compose an opera with my scientific friends as the characters, I should associate the Melisande theme with the first Mrs. Ayrton; I should not quite know where to place the second musically but it would be near to Brunhilde, as she had much of the vigour of Wotan's masterful daughter and, at least, aspired to be an active companion of scientific heroes—a race far above Wagner's dull and degenerate Teutonic gods, be it said.

Sarah Marks was the daughter of intelligent but poor Jewish parents in Portsmouth. She was a clever child and was early sent to a school in London kept by her paternal aunt, who became Mrs. Hartog; Mr. Hartog was a teacher of French in London. Mrs. Hartog was the mother of Numa Hartog, Philip Hartog and the professor of botany in Cork; also of two daughters, one very clever, a talented painter, who married Dr. Darmstadter of Paris; the other earned her living as a musician. Numa Hartog died early, after a most brilliant university career and seems to have been unusually clever. Mrs. Marks had four undistinguished children, besides Sarah; nothing is known of her parents. Mrs. Ayrton's ability, however,

would seem to have been derived from the mother's side.

At about the age of fifteen, Sarah Marks became acquainted with Madame Bodichon, a well-to-do lady, strong on the women's rights question, who sent her young friend to Girton College, Cambridge. Apparently, she then changed her name to Hertha. She took honours in mathematics. She is credited with the invention, during the period, of a sphygmograph and also of an instrument for rapidly dividing up a line into a number of equal parts. Through Madame Bodichon, she became acquainted with George Eliot and several other people of distinction. In 1884 she entered the Finsbury Technical College. I remember her coming. She not only came but was seen and soon conquered—Ayrton; and they married. As sole issue they had a daughter, who has her father's gift of tongue; she married a Christian, whilst his daughter by his first wife married a Jew. I often told him that he and his wife were an ill-assorted couple: being both enthusiastic and having cognate interests, they constantly worried each other about the work they were doing. He should have had a humdrum wife, "an active, useful sort of person," such as Lady Catherine recommended Mr. Collins to marry, who would have put him into carpet-slippers when he came home, fed him well and led him not to worry either himself or other people, especially other people; then he would have lived a longer and a happier life and done far more effective work, I believe.

Under her husband's inspiration, Mrs. Ayrton soon entered upon the study of the electric arc. Her work is recorded in the book on the subject which she published in 1902, in part a reprint of papers submitted to the Royal and other Societies. She was an indefatigable and skilful worker. Whatever the absolute value of her observations, her husband and his good friend Perry were the last not to make the most of her achievement, so probably the scientific halo with which they and others who fancied that women could be as men surrounded her was overpainted. Most of us thought, at the time, that they were ill advised in preferring her claim to the Royal Society; the nomination came to nothing on legal grounds. She was, however, elected into the Institution of Electrical Engineers and at her death was its only lady member. She also engaged in an inquiry into the formation of sand ripples and this led her, early in the War, when chlorine was first used as poison gas, to develop a fan-device for waving back the fumes. There is little doubt that she took too high a view of the practical value of the invention and was unwarrantably aggrieved at its rejection by the military authorities. She was awarded the Hughes Medal by the Royal Society in 1906.

Mrs. Ayrton was a very striking woman in appearance and of considerable personal charm, full of common sense; this kept her from being a militant suffragist, though she promoted the cause in every possible way. I never saw reason to believe that she was original in any special degree; indeed, I always thought that she was far more subject to her husband's lead than either he or she imagined. Probably she never had a thorough scientific equipment; though a capable worker, she was a complete specialist and had neither the extent nor depth of knowledge, the penetrative faculty, required to give her entire grasp of her subject. Ayrton himself, though a genius, was in no slight measure partial in his interests: by heredity literary and artistic, educated intensively in the classical school, a born actor and therefore a good lecturer and public speaker, impelled into science through contact with Sir William Thomson, he was a worker chiefly at its technical and commercial fringe rather than in its depths: so he was not a good judge of his wife's scientific ability. His partner Perry was the solid member of the firm. In fine, my conclusion is, that *das ewig Weibliche* was in no way overcome in Mrs. Ayrton: nor could we wish that a thing so infinitely precious should be: she was a good woman, despite of her being tinged with the scientific afflatus.

Henry E. Armstrong.

Dr. J. E. Stead, F.R.S.

By the death of Dr. John Edward Stead, on October 31, at the age of seventy-two, Great Britain has lost one of its most famous metallurgists, a man who played a very honourable and a leading part in the development of scientific metallurgy, and is not unworthy to be ranked with the great names of John Percy, Lowthian Bell, and Roberts-Austen.

Dr. Stead was born in 1851 and was a younger brother of the late W. T. Stead. After the usual period spent at school, he was for a time an evening student at the Owens College, Manchester, in the early days at Quay Street. From there he passed to a steel works in the Middlesbrough district, where he served his apprenticeship on the practical side of iron and steel smelting, but he was only nineteen when he entered the laboratories of Pattinson, a consulting chemist and metallurgist in the district. Later the two men entered into partnership under the title of Pattinson and Stead, and he remained identified with the firm for the remainder of his life, a period of about fifty-two years in all. He became one of the best-known analysts in the north of England, and one can only conjecture how many large contracts were signed on the basis of Stead's analyses.

An incident related to the writer some twenty years ago by Dr. Stead will give some idea of how this man, with a very slight amount of what would be termed academic training, rose to a position of great power and trust, not merely in the Cleveland district where he lived, but also in the iron and steel industry of the whole country. He found on one occasion, in the early days of his association with Pattinson, that he had sent an incorrect analysis to one of the firm's clients. Without hesitation he wrote to explain that he had made a mistake and substituted the correct figures. The client in question was exceedingly angry, not because he had received an incorrect analysis, but because Stead had admitted that he had made a mistake. Apparently this is a serious matter where business is concerned. Stead retorted, "If I was unwilling to admit that I made mistakes, you would never know whether a result I sent you was correct or not." This was a new point of view, and the client was so much impressed by it, that he sent all his

analyses to Stead in the future, after having previously threatened to withdraw his custom.

It is not as an analyst, however, that Stead rose to fame. He was naturally of an inquiring mind, eager to discover truth in any form that he could, and in the course of forty-six years he published at least eighty papers before seventeen institutions, in which he covered a range of subjects in the metallurgy of iron and steel, such as few, if any other, men have attempted. If he could be said to have made one subject rather than another peculiarly his own, it was the influence of phosphorus on iron. This was perfectly natural, for the Cleveland ores are phosphoric, and phosphorus, at any rate in association with carbon, is the worst enemy of steel. It is not generally known that Stead played a very important part in the early days of the development of the Thomas-Gilchrist basic Bessemer process for the dephosphorisation of phosphoric iron ores, a process which enabled Germany to become the second largest producer of steel in the world, with all the consequences that have followed. One of the essential features of the process is the so-called "afterblow," when the blowing of air through the converter is continued after the complete removal of carbon. Stead was the first to advance the correct explanation of what takes place, namely, that phosphorus is removed during this period, but not until then, by iron oxide. Thomas and Gilchrist challenged this explanation and only accepted it in the following year when they obtained letters patent for the "afterblow."

Stead was one of the first men in Great Britain to realise the importance of Sorby's investigations, which led to the foundation of metallography as a science. With true vision he saw that here was a new experimental weapon for investigating the properties of all metals and alloys, and the majority of his investigations have lain in this field. Within the limits of this article it is impossible to give any adequate idea of their scope and variety, but this, at all events, may be said, that his contributions to our knowledge of the crystallisation phenomena observed in iron and steel, and the segregatory and migratory habits of solids in alloys, were such that he became one of the chief authorities in the world on these subjects. He made important contributions to the technique of microscopic metallography, and his method of heat-tinting specimens by oxidation became an accepted method for the micro-analysis of cast iron.

Living as he did to the age of seventy-two, it would have been very surprising if honours had not come to Stead. He became a member of council of the Iron and Steel Institute in 1895, a vice-president in 1910, and president in 1920. He received the Bessemer medal of the Institute in 1901. In 1910 he was president of Section B of the British Association at Sheffield. He also filled the office of president of the Cleveland Institution of Engineers. The majority of his papers were published before these two Institutions. He was given honorary doctorates of the Universities of Manchester, Leeds, and Sheffield, and he had been for twenty years a fellow of the Royal Society.

No man revealed himself more characteristically in his papers than Stead. He had a generous and ardent mind, and he pursued the search for truth with a single-mindedness which was an inspiration to all who knew him. The willingness to admit that he was wrong when he was wrong, which is not so common a virtue as it should be, and to which attention has already been directed, made him an ideal opponent in scientific controversy. Characteristically enough, he was particularly generous to young workers in the field of metallurgy, imbuing them with something of his knowledge and enthusiasm, and encouraging them by generous praise. The writer recalls several such occasions in his own experience. During the last eighteen months Stead had been forced to live in retirement and indeed had become a physical invalid, but his mind remained clear and active up to the time of his death. He leaves behind him the memory of a life splendidly lived, which those who were privileged to know him will always cherish.

H. C. H. CARPENTER.

M. MAURICE LEBLANC.

BY the death of Maurice Leblanc on October 27, the world loses one of its greatest engineers. He had striking originality. In conjunction with M. Hutin, he invented the *amortisseur* or damping coil, which when applied to alternators enables them to run steadily in parallel. He also perfected the method of converting induction motors into generators by driving their rotors at speeds greater than synchronism by prime movers. He ran them in parallel, the frequency of the supply depending only on a small alternator in the supply circuit, the function of which he compared with that of a *chef d'orchestre*. In recent years he devised a remarkable system for high-speed electric traction. The energy is communicated to the moving train without rubbing contacts by means of magnetic induction. He proposed to utilise alternating currents having frequencies of 20,000, the current being carried over the track by a series of tubular condensers adjusted to resonance. The currents in the locomotive circuits are converted to low frequency by thermionic valves. They then operate induction motors as in ordinary traction systems.

In the very difficult years 1912–1914 Leblanc filled the post of president of the International Electrotechnical Commission with universal acceptance. His speech when resigning the office of president at the London meeting in 1919 was a powerful plea for nations and individuals to give up working exclusively for selfish ends. The lack of this in the past had led to the greatest catastrophe of all time. "From henceforth only productive work will be deemed honourable." He was elected an honorary member of the Institution of Electrical Engineers in 1915. His high ideals and singleness of purpose made friends for him in every country of the world.

A. R.

WE regret to announce the following deaths:

Mr. Thomas Pridgin Teale, F.R.S., the eminent surgeon and sanitarian, on November 13, aged ninety-two.

Dr. Boris Sidis, of the Sidis Psychotherapeutic Institute, Portsmouth, New Hampshire, known for his work on the psychology of suggestion and mental dissociation, on October 25, aged fifty-six.

Current Topics and Events.

THE Western Galleries of the Science Museum, South Kensington, which for nearly half a century have contained the valuable Science Collections of the Museum, were closed to the public on September 17. These galleries have now been vacated, and the constructional and other work (gun foundations, re-decoration, etc.) considered by the Government to be necessary to make the galleries fit to house the collections and staff of the Imperial War Museum (created a few years ago, and now at the Crystal Palace) is already well in hand. The Science Collections have been transferred to three unfinished galleries in the eastern block of the new Science Museum building (see NATURE, June 30, p. 895), which were not vacated by the Post Office Savings Bank department until towards the end of September. The total floor-area available in these galleries is only about two-thirds that in the Western Galleries, which were already much overcrowded; but by using two of the new galleries as store-rooms, in which objects are packed very closely together, it has been possible to arrange objects in the third gallery under conditions which allowed this gallery to be open to the public from November 11. Here are shown groups of objects selected from the sections illustrating astronomy, surveying, meteorology, chemistry, optics, sound, and botany. The remaining objects in these sections, and all the objects in the sections illustrating mathematics, general physics, photography, kinematography, heat, geophysics, geology, geography, and oceanography—forming altogether about eighty per cent. of the Science Collections—are thus stored away, and cannot be placed on exhibition again until further space becomes available. The progress made during recent years with the fine new buildings of the National Science Museums of Germany and Austria, at Munich and Vienna respectively, affords a significant contrast to the above.

THE Council of the Trade Marks, Patents, and Designs Federation, Ltd., recently circulated a questionnaire in relation to trade marks, patents, and designs prepared by the International Chamber of Commerce to a number of societies interested in these matters. This questionnaire was drawn up with the object of ascertaining the directions in which modifications and amendments were desirable, from the British point of view, in the International Convention for the Protection of Industrial Property (Treaties Series, No. 8 (1913). Cmd. 6805. H.M.S.O. Price 6*d*. net.), signed at Washington on June 2, 1911 (State Papers, vol. 104, p. 116). A meeting of the representatives of some twenty of the societies consulted was held at Lever House, Blackfriars, on November 23. The questionnaire was discussed, and it was recommended, *inter alia*, that (1) a clause should be inserted in the Convention abolishing revocation of patent rights either for non-working or for abuse of monopoly, but permitting each country at its discretion to grant compulsory licences in such cases; (2) provision should be made for establishing in all Convention countries a uniform period of duration for patents, and renewal fees should be paid at agreed intervals of time and be based on a sliding scale system of progressively increasing payments; (3) there should be uniform provisions governing the use of an invention on vessels sailing under the flag of one of the States which has adhered to the Convention; (4) there should be provision for registration in a public register kept by the competent administration of each country of all assignments and licences affecting the legal proprietorship of patent rights; (5) steps should be taken to secure a greater degree of uniformity in the regulations at present in force in the various Convention countries with respect to the procedure to be followed on applications for the grant of letters patent. It was further agreed that it was neither desirable nor practicable to insist upon the institution in all Convention countries of a system of preliminary search of patent applications, but it was desirable that any party interested should have the right, prior to the grant of any patent, to institute opposition proceedings based on all prior publications or public users of the invention of which he has knowledge.

THE British Meteorological Office announces an mportant step towards supplying ships with information regarding the existing weather around the British coasts and forecasts for the seas adjacent to the British Isles. On January 1 a new series of broadcast wireless messages will be issued from the Air Ministry Station at 9 A.M. and 8 P.M. daily. Each message will contain the actual observations of wind, weather, pressure, barometric tendency, and visibility at ten stations on the British coasts taken only two hours before the broadcast issue. The messages will also give a general inference of weather conditions and forecasts for twelve hours for eleven sea districts; at the end a further outlook will be given when possible. The code and full particulars may be found in the Board of Trade notices to mariners for November or in the *Marine Observer*, a monthly magazine to be published by His Majesty's Stationery Office from the beginning of 1924.

IN an address delivered before the Scientific and Technical Circle of the Institute of Journalists on November 20, Sir Richard Gregory, the chairman, discussed the relation of science to progress. In his opening remarks he recalled that Ruskin in his "Crown of Wild Olive," George Gissing in his "Private Papers of Henry Ryecroft," and many other writers had associated science with agencies of death or denounced it as detrimental to social culture. This, however, is a narrow view, and it is futile to rail against the progress of science or attempt to prevent it. We are now on the threshold of developments by which forces may be unloosed and powers acquired far beyond those hitherto known to man. Science is no more responsible for the horrors of the War than for soul-destroying industrial conditions. Scientific discoveries may be used for the benefit of mankind or be applied to base uses. Thus

chlorine, the first poison-gas used in the War, had for more than a hundred years previously been used as a bleaching agent. Nitre, though a constituent of explosives, has been used in fertilisers with such success that the average yield of wheat per acre in England is now 30 bushels instead of 20 bushels as in the seventeenth century. The vast development in the production and export of cotton piece-goods is due to science and invention. China has vast stores of anthracite coal and other minerals, but because of the lack of scientific knowledge and ability to exploit these resources, most of the people of that country live in comparative poverty. It is impossible to foresee the applications of discoveries. Minerals which a few years ago were scientific curiosities, rare gases like neon, argon, and helium, have now uses unsuspected by the discoverers. It is our duty to see that the powers which science gives to the human race should be used for noble and spiritual purposes, so that they may be a blessing to mankind instead of a curse.

The next Congress of the Royal Sanitary Institute will be held at Liverpool on July 14-19, 1924, by invitation of the Lord Mayor and City Council.

Sir Arthur Keith will deliver the Thomas Vicary lecture of the Royal College of Surgeons of England in the theatre of the College in Lincoln's Inn Fields on Friday, December 7, at 5 o'clock. The subject of the lecture will be "The Life and Times of William Clift, First Conservator."

At the November meeting of the Royal Statistical Society, the Frances Wood Memorial prize, value 30*l.*, which is offered biennially for the best investigation of any problem dealing with the economic or social conditions of the wage-earning classes, was awarded to Miss E. J. M. Haynes, of Oxford, for an essay on human power in the English pottery industry.

The Liverpool Psychological Society has been inaugurated under the presidency of Prof. Alexander Mair of the University of Liverpool, supported by Dr. Betts Taplin as vice-president and an influential committee. The Society intends to pursue the systematic investigation of the recent developments of the science. Further information can be obtained from the secretary of the Society, the University, Liverpool.

A junior assistant is required by the Royal Aircraft Establishment, South Farnborough, Hants, for aerodynamic research in wind tunnels. Candidates for the post must possess a good knowledge of physics and applied mathematics and an honours degree in natural science or engineering. Applications, marked Ref. A. 23, should be sent to the Superintendent of the Royal Aircraft Establishment.

Applications are invited by the Queensland Government for the position of Director of the Laboratory of Microbiology and Pathology of the Department of Public Health, Brisbane. Candidates must hold a diploma in public health and have had recent special laboratory experience in microbiology. The Agent-General for Queensland, 409 Strand, W.C.2, will supply further information respecting the post. The latest date for the receipt of applications is December 17.

An Inspector is required by the Ministry of Agriculture and Fisheries in connexion with agricultural and horticultural education and research. Candidates must have taken a University or Agricultural College course in science or agriculture and have had special training in the science and practice of poultry and small livestock keeping—including goats and rabbits. Forms of application, etc., may be had from the Secretary of the Ministry, 10 Whitehall Place, S.W.1. They must be returned by, at latest, December 8.

The Committee of the Christie Hospital, Manchester, is offering a prize of 300*l.* for cancer research. The aim is to stimulate isolated work, particularly that already in progress, apart from the research schemes of cancer research institutions; for the Committee thinks that notable increase in the knowledge of cancer may come from an individual worker as well as from a team of men investigating the subject systematically. At the same time, the Committee intends to keep up its own research work at the University of Manchester. Since advances may be expected from sciences allied to medicine, the conditions attached to the prize are very wide. Candidates must be qualified in medicine, or in science cognate to medicine, and must produce evidence of original research on cancer done or projected. All documents must be submitted in English, but nationality is no condition of the award. Applications must reach the chairman of the Medical Board, Christie Hospital, Manchester, not later than December 31, 1924.

In June the Canadian explorer, Dr. V. Stefansson, directed the attention of the Textile Department of the University of Leeds to the wool of the Ovibos (musk ox), which is capable of being bred in large numbers in the arctic zone of Canada and might be a considerable asset to the Dominion. The wool, of a natural brown colour, is hidden by an overgrowth of long hair, which is troublesome in manufacture. The first specimen woven in the Department was brought to the notice of the King at the time of the meeting of the Imperial Conference in October. Samples have been dyed successfully, and further experiments are in progress to eliminate the long hairs. The Clothworkers' Company of London, to whom the University is so greatly indebted in many ways, and particularly for the building, equipment, and endowment of the Textile Industries and Dyeing Departments, is showing a keen interest in these important experiments.

The winter scientific reunion of the Natural History Museum Staff Association was held in the Board Room of the Museum on November 14, and attracted a large attendance of the staff and other workers in natural history. Many, varied, and interesting specimens were exhibited, among which may be mentioned: Fossil Arachnida from the Rhynie Chert, Old Red Sandstone, Aberdeenshire (the oldest recorded instance

of Arachnida); examples of sex dimorphism in cuttle-fish; the second and third cervical vertebræ of a Sibbald's rorqual (revealing the exceptional size of the original whale); cast of the skull of *Baluchitherium Grangeri* from the Miocene, Central Mongolia; examples illustrating the germination of the coco-nut; selection of minerals collected by Mr. F. N. Ashcroft from Cavradi and Sedrun, Switzerland; example of a fish, *Gigantura chuni*, which had swallowed another, Chauliodus, double its length; a series of reproductions of remarkable photographs of African big game. The Cambridge and Paul Instrument Company demonstrated microtomes manufactured by that firm.

Dr. S. Judd Lewis has been awarded the gold research medal of the Worshipful Company of Dyers, on the recommendation of the Society of Dyers and Colourists, for his work on the quantitative determination of the fluorescent power of various forms of cellulose and its derivatives, published in the Journal of the Society. It has been shown that the form and dimensions of the fluorescence curve, having as its co-ordinates the wave-length and fluorescent power per cent. relative to a standard paper, are related to the chemical constitution of the substance. The curves for pure cellulose, hydrocellulose, oxycellulose, cellulose acetate, etc., as well as those for various sugars, are all characteristic, with peculiarities in common for those substances of similar structure. The physical condition of the material has very little effect on the results. It is anticipated that this new method, which is conducted photographically, will prove useful in throwing light on the constitution of opaque solid substances in much the same way as absorption spectroscopy is applied to the investigation of transparent fluids.

Mr. F. Edwards, 83 High Street, Marylebone, has just circulated Catalogue No. 452 of nearly 1400 books of voyages, travels, exploration, and sport. Among the works listed are the first edition of Hakluyt's "Navigations," etc., a complete set of the second series, to 1922, of the Hakluyt Society Publications, and a set of the Journal and Proceedings of the Royal Geographical Society to 1919. The same bookseller has also sent us a selected list of books, engravings, and maps relating to West Africa.

Among the new announcements of Messrs. Macmillan and Co., Ltd., to which attention has not hitherto been directed in Nature, are the following: The Autobiography of Sir Archibald Geikie; "A Glimpse of the Natives of Central Australia," by Dr. G. Horne and G. Aiston, which will deal with the country, the habits, customs, and beliefs of the Wonkonguru and their neighbours (much of the information has been collected at first-hand from the natives); and the collected works on Economics of Prof. F. Y. Edgeworth, in 3 vols., with introductions to the various sections by the author.

Our Astronomical Column.

Reinmuth's Cometary Object.—After considerable delay, owing to its faintness, a third photographic observation of this object was obtained by Graff and Baade at Bergedorf. Stracke has deduced the following elliptical elements:

T	1923, Nov. 28·92 G.M.T.
ω	182° 58′ 19″
Ω	229 17 10
i	16 18 4
e	0·4701
log q	0·1621
Period	4·537 years.

The Bergedorf plate showed no nebulosity, so the object may be a minor planet, of the type of Aethra. Its perihelion is well within the orbit of Mars. Its position at midnight on Dec. 3 is R.A. $1^h\ 47{\cdot}5^m$, N. Decl. 6° 27′; daily motion $+1{\cdot}55^m$, S. 18′.

The Total Solar Eclipse of September 10.—*Popular Astronomy* for October contains a photograph of the corona taken at Lompoc, California, by Mr. Worthington. The scale is too small to show much detail, but the outline conforms to the type of sunspot minimum.

The Sproul Observatory at Durengo, Mexico, the Steward Observatory expedition on the Gulf of California, and the Mexican and German expeditions at Yerbaniz, Berrendo, and Pasage (all in Mexico), all enjoyed good conditions and were able to carry out their programmes. Most of the other parties were partly or wholly clouded out.

Mr. Morgen Brooks ascended a mountain in Catalina Island and obtained some very interesting views of the passage of the shadow on the clouds. He makes the usual remark that light seemed to increase more rapidly than it diminished. This is probably subjective, one's eyes becoming more sensitive during the darkness. He saw no shadow-bands.

A Remarkable Meteoric Procession.—A swarm of light meteors was seen on February 9, 1913, to pass over Canada, the United States, and the Atlantic, the length of the track being several thousands of miles. Prof. W. H. Pickering has made a study of their motion in *Popular Astronomy*, proving that their orbit before encountering the earth cannot have been of a cometary character, but must have been an ellipse not very different from the orbit of the earth itself, to permit the relative velocity to be so small. This would tend to support the view of the late Sir Robert Ball that the slow-moving fireballs were probably ejected from terrestrial volcanoes in the distant past. Their velocity on emerging from proximity to the earth would not be very different from the earth's velocity, and their subsequent orbits would be close to that of the earth.

Prof. Pickering notes that it is quite likely that (with the aid of the moon) some of these bodies may have been captured as satellites of the earth and revolve around it above the atmosphere. When they enter the latter they ultimately descend to the ground.

A Projected French Observatory.—*La Nature* of November 3 states that M. Dina, an engineer, is endowing an important new observatory at Cruseilles in Haute-Savoie. He has recently discussed the plans with General Ferrié and MM. H. Deslandres and A. Danjon. It is expected that a large reflector will be included in the equipment, which will probably be devoted mainly to researches in astrophysics. Meteorology w ll also occupy an important place in the work o the observatory. It may be presumed that the quality of seeing has been already studied at the proposed site, as this is of such vital importance in the case of large aperture instruments.

Research Items.

Red Deer from the Holderness Peat.—Two discoveries of the remains of red deer in the peat of Holderness are recorded by Mr. T. Sheppard in the November issue of the *Naturalist*. The first was found in beds exposed on the shore near Skipsea, East Yorks. The entire skeleton with the exception of a few small bones was recovered and is now exhibited in the Municipal Museum at Hull. The antlers measure 2 ft. 3 in., and 2 ft. 2½ in., one having seven and the other six points. The second discovery was made in the peat on the shore at Withernsea at very low water during the spring tides. Consequently little time was available for excavation and only the antlers were secured. The right antler measured 33 in. in length and 9 in. in diameter at the skull. The left antler was unfortunately broken in the course of excavation and only a part recovered.

Geographical Work in Egypt.—The Ministry of Public Works, Egypt, publishes the report on the work of the Physical Department for the year ending March 31, 1923. In the Hydrological Service, rainfall observations were received from 281 stations in Egypt and surrounding lands, an increase of ten compared with the previous year. The Nile basin is fairly well supplied with stations except Abyssinia, where there are only six. River discharge measurements were taken on all the main branches of the Nile. A discharge station at Nimule, on the borders of the Sudan and Uganda, will give a measure of the amount of water available for storage in Lake Albert which is essential in any project for controlling the waters of that lake. Among numerous other researches it may be noted that experiments were made with hydrogen drift balloons carrying a magnesium flash mixture, in order to connect, by the help of a camera, the European and African triangulations by way of Crete. The Meteorological Service now receives observations from twenty-four stations in Egypt and twenty-nine in the Sudan. A station in the Sinai peninsula at Bir Abu Tif, founded two years ago by a commercial company, was closed.

Flora of the Tibetan Marshes.—The ecologist will find an interesting description of a little-known region in Mr. F. Kingdon Ward's account of the flora of the Tibetan marshes in the Journal of the Royal Horticultural Society, volume 48, parts 2 and 3, issued September 1923. He describes the glaciated limestone plateau east of the Yangtze, a country of wide Alpine valleys and numerous small lakes with frequent lofty escarpments overlooking the rivers running from north to south. This country appears to be magnificently rich in herbaceous alpines, which are unaffected by the seasonal droughts occurring in their non-growing season, while these conditions prevent the vigorous development of woody plants. As opposed to the country to its west, it is a land of primulas rather than of rhododendrons. Mr. Ward's account of the vegetation is none the less interesting because it is written with a special reference to the plants which are of horticultural interest when transferred to the amateur's garden. Many students of rock gardens will be interested by his pertinent remarks, based upon the study of the rock flora in Nature, as to the places where certain plants should appear in the garden. Thus he suggests that plants with translucent flowers, such as a species of Onosma, are intended to grow on a level with the eye so that the light reaches the observer through the petals of the flower, while others, like some of the dwarf Campanulas, are intended to hang downwards from the crevices in the cliff.

Lignite in Nigeria.—The Bulletin of the Imperial Institute, volume 21, No. 2, 1923, contains an important article upon the lignite deposits of Nigeria, which are to be found on both banks of the Niger and seem likely to afford a practicable fuel of special value for boats navigating the Niger. The geological relations of the lignite deposits in the Southern Provinces of Nigeria are discussed and the distribution of the beds indicated so far as it is known. Analyses of the chemical composition of samples from various seams are presented and trials reported of the suitability of the lignite for manufacture into briquettes. A large scale trial of the Nigeria lignite was made by making up a considerable amount of the material into briquettes through the co-operation of a factory in Saxony; these bricks were then used in locomotives on the railways in both the northern and southern provinces of Nigeria with results that suggest that they will provide quite a satisfactory fuel. In view of the cost of imported coal in British West Africa the subject would seem to be of considerable economic importance.

New Oligocene Toothed Cetacean from South Carolina.—Mr. R. Kellogg figures and describes (Smithsonian Miscellaneous Collections, vol. lxxvi. No. 7) an apparently new toothed Cetacean from beds probably of Oligocene age in Berkeley County, South Carolina. The fossil consists of a skull 371 mm. (=14½ in.) in length. In some respects it resembles Agorophius and Archæodelphis, but is considered to represent a new genus and species and has been named *Xenorophus sloanii*.

Italian Earthquakes in 1911.—For the first time since the War, the Central Office of Meteorology and Geodynamics at Rome has issued its "Notices of Earthquakes observed in Italy." The present volume of nearly 600 pages deals with the earthquakes of the year 1911 and forms an appendix to vol. xviii. (1914) of the Bollettino of the Italian Seismological Society. One advantage of late publication is that the results obtained at foreign observatories can be incorporated. The total number of earthquakes recorded in 1911 is about 800, of which one-fifth were of external origin. Of the latter, one in every three is described as a "distant earthquake," the position of its origin being apparently undetermined.

The Cheiropterygium in Amphibia.—Cope's genus Eryops, an early Labyrinthodont from the Permian of Texas and New Mexico, has been much discussed; but new light is now shed on it by a paper on its carpus, by W. K. Gregory, R. W. Miner, and G. K. Noble (Bull. Amer. Museum of Nat. Hist., vol. 48, p. 279, Oct. 17, 1923). The authors point to the primitive characters revealed by their research, and come to the far-reaching conclusion that, while all known fossil and existing amphibia have four digits in the manus, the most primitive forms had "a prepollex, five digits, and a postminimus" in the hand and similar features following a prehallux in the foot. The cheiropterygium was thus at least seven-rayed, with a tendency to reduction in the two marginal rays. It is pertinent to the recent discussion in Nature as to the spelling of names derived from Greek that "cheiropterygium" in this paper is not only docked of its first "i," but, when broken at the end of a line, has the hyphen placed between the "p" and the "t."

Coral-reefs and Coastal Platforms.—The papers on coral-reefs recently read by W. M. Davis before the National Academy of Sciences, Washington, D.C., and

referred to in NATURE (vol. 112, p. 460), have now been printed in the Proceedings of the Academy, vol. 9, pp. 292 and 296. The first deals with the marginal belts of coral seas, and it is pointed out that platforms of low-level abrasion are not known in association with the islands in the cooler zones of the Pacific region, while their depth below sea-level is not so uniform where they do occur as to satisfy Daly's theory of glacial control. If we accept glacial control, as Davis is quite willing to do, the evidence for subsidences of various degrees of magnitude, as put forward by Darwin, remains unimpaired. The second paper deals with the argument based on the uniformity of depth of the lagoons within adjacent atolls, and the author urges that level floors arise through infilling with detritus, which is spread out evenly by the wash of marine water.

PLANTS OF THE MIDDLE OLD RED SANDSTONE.—R. Kidston and W. H. Lang (Trans. R. Soc. Edin., vol. 53, pt. 2, p. 409, 1923) have investigated and completely described the remains of *Palæopitys Milleri* McNab, a plant originally found by Hugh Miller in beds containing *Coccosteus decipiens* near Cromarty. The authors confirm McNab's observation of bordered pits in the tracheides; but they are unable to decide, in the absence of any evidence as to the fructification, whether the genus should be referred to the gymnosperms or to the pteridophyta. In either case it is probably a distinctly archaic type. The same authors (*ibid.* p. 405) describe, and figure in a photographic plate, an extremely beautiful specimen of a plant with numerous stems spreading radially from a basal region. This was collected by G. Edward, and described by him in 1888. Edward placed it, with his other specimens from Scotland, in the Manchester Museum. Its locality is the Hill of Forss, Waas, Caithness, and it is of Middle Old Red Sandstone age. Sporangia set on short stalks occur; but G. Hickling, when on the staff of the University of Manchester, examined these for spores in vain. The authors now give a name to the plant, *Hicklingia Edwardi*, and seek its affinities in forms from the famous Rhynie cherts. It may be found, indeed, that Hicklingia extends our knowledge of the Rhyniaceæ.

DAILY AND SEASONAL VARIATIONS OF FOG.—The Meteorological Office of the Air Ministry has recently issued a Professional Note, vol. iii., No. 33, by Mr. F. Entwistle, on the above subject. Observations of fog from April 1920 to March 1922, a period of 2 years, were grouped for each month at Croydon, Lympne, Cranwell, and Dungeness for all hours of the day for which observations were made. A temporary increase in fog is shown in the early morning, a maximum being reached between one and two hours after sunrise. The summer maximum occurs about three hours earlier than the winter maximum. London smoke naturally somewhat affects the general visibility at Croydon, being influenced by the direction of the wind. Increase of fog in the early morning is said to be due probably to eddy motion mixing the layers of air near the surface. There is generally less fog during the afternoon, between midday and 6 P.M., than at any other time during daylight. For civil aviation it is considered desirable to arrange early morning services, before the maximum fog intensity is reached, while for ordinary services the middle of the day is the best time. In the winter season the larger proportion of slight fogs at Croydon are doubtless due to town influence. The thick fogs at Lympne are due chiefly to low cloud caused mainly by winds between south to south-west, so that the high ground of the North and South Downs is enveloped. The small amount of fog in winter at Dungeness seems to suggest that the best position for an aerodrome in winter is on the coast near sea level. In the summer months thick fog is frequent at Lympne and Dungeness; at Dungeness it is chiefly sea fog caused by the relatively warm air from off the land passing over the cooler sea.

FORMATION OF OZONE IN FLAMES.—Prof. Manchot, of Munich, communicated to the autumn congress of German Chemists at Jena a paper on the formation of ozone in flames. Parts of the flame which have a temperature of 750° C. only contain ozone, as can be proved by the silver reaction. The formation of ozone does not depend on the nature of the combustible gas, ozone being formed with hydrogen, carbon monoxide, methane, acetylene, cyanogen, etc. A flame of oxygen and hydrogen gas of 1300°-1900° C. contains about 0·1 per cent. of ozone, one of acetylene and oxygen of 2100° C. about 1 per cent. The latter blackens silver as if it were covered with soot. The thermal formation of ozone, and also the formation from hydrogen peroxide, are not possible, since ozone is also formed within a flame of perfectly dry carbon monoxide. It is probable that the ozone is formed by the action of electrons.

STANDARDISING PIEZO-ELECTRIC APPARATUS.—The extensive use of the piezo-electric properties of crystals in the measurement of transient pressures such as those due to an explosion makes it necessary to inquire into the validity of the method used to standardise the apparatus. It has generally been considered sufficient to apply a steady known pressure to the crystal and to note the effect. In a short paper in the November issue of the *Philosophical Magazine*, Dr. D. A. Keys, of the McGill University, Montreal, points out that as the standardisation experiment is an isothermal and the ordinary use an adiabatic one, there may be a difference in the piezo-electric constant of the crystal in the two cases. He examines this possibility in the case of tourmaline and comes to the conclusion that for that crystal the difference between the isothermal and adiabatic constants is only ½ per cent.

CHANGES IN CRYSTALLINE STRUCTURE DUE TO TEMPERATURE.—Describing a simple arrangement for showing the alteration in the appearance, under the microscope, of a polished etched metal plate when heated, Herr H. Vogel, in the *Zeitschrift für Elektrochemie*, July 1, 1923, makes the following assumption as to the behaviour of the crystallites, of which the metal is built up. If two crystallites touch one another, the distance between the atoms in the boundary plane of one of them will, in general, be greater than in that of the other, and the forces holding the atoms in these respective planes will be different. When the metal is heated the first crystal will grow at the expense of the other, and as this takes place throughout the metal, the average size of the crystallites increases. It is possible for a crystallite to grow on one side and be consumed by another crystallite on another, so that the relation between the initial and the final structure may be complicated. The distance between atoms in the octohedron plane is greater than in the cube surfaces of the lattice, and it is still greater in the rhombic dodecahedron surfaces; thus when two crystals *A* and *C* touch with surfaces of the first and third kind, crystal *A* grows; while when *A* and *B* touch with surfaces of the first and second kind, crystal *B* grows and *A* is consumed.

CHEMICAL ANALYSIS BY X-RAYS.—In a paper read before the Deutschen Bunsen-Gesellschaft, Dr. D. Coster shows that the relations between the X-ray spectra of the different elements are so simple that, in

some respects, they are more useful for purposes of chemical analysis than ordinary luminous spectra (*Zeitschrift für Elektrochemie*, Aug. 1, 1923). An important advantage is the fact that the X-ray spectrum of an element is quite independent of the nature of the compound containing it which is examined. It is easy to detect the presence of an element when only 1 per cent. is present in a mixture of which not more than 1 mg. is available. Certain precautions are necessary in examining the X-ray spectra; although the number of lines for each element is comparatively limited, recent observations have shown the existence of a number of weaker lines; in addition to this, with the high voltages now generally used, not only the spectrum of the first order, but also those of higher orders appear. Slight impurities in the material of the anticathode, and in the substance under examination, also give their lines, so that there are often various possibilities to be considered before a given line can be explained. Not only the wave-length, but also the typical appearance of the suspected lines must be considered, as well as their relative intensity. By measuring photometrically the intensity of the spectral lines it is possible, in some cases, to obtain a quantitative estimate of the amount of an element present in a mixture. The method was used by Hevesy and the author in determining the amount of hafnium in zirconium minerals, and in investigating the chemical properties of the new element.

Magnetic Records of the British Isles.—The British Meteorological and Magnetic Year Book for 1920, published by the Meteorological Office, gives particulars of the diurnal variation of the principal meteorological elements at the Aberdeen, Eskdalemuir, Valencia, and Kew Observatories, with rainfall and sunshine data at Falmouth. The major portion of the volume, however, is devoted to terrestrial magnetism, especially at Eskdalemuir. Two pages are devoted to the diurnal variation of the potential gradient of atmospheric electricity. The results for Kew are based on 10 selected days a month free from negative potential. For Eskdalemuir there are two sets of data, the first derived like the Kew data from days free from negative potential, the second from days when negative potential occurred, although they were comparatively quiet. Taking the first class of days, the mean value of potential gradient at Eskdalemuir for summer (May to August) is practically identical with that at Kew. In the other seasons the Kew value is the greater, the excess being 9 per cent. for the equinoctial and 45 for the winter season. The difference is thus greatest in the months when fog—a recognised source of high potential—is most prevalent in the Thames valley. In addition to the regular tables of hourly values and diurnal inequalities of terrestrial magnetism, there is a discussion by Dr. Crichton Mitchell of different measures of daily magnetic activity at Eskdalemuir. All his criteria make 1920 a quieter year than 1919, and the same conclusion is drawn from the Kew data. There was, however, an exceptionally violent magnetic storm on March 22-23, 1920, during which the range of declination at Kew exceeded 2°. According to the table on p. 47, the fall of westerly declination from 1919 to 1920 was 9·9′ at Kew, 9·3′ at Valencia, and 9·0′ at Eskdalemuir. Inclination appeared to be practically stationary, while horizontal force showed a slight fall: 7γ at Eskdalemuir, 6γ at Kew, and 2γ at Valencia.

Photographic Blackening and Coloured Light.—The second number (August) of the Bulletin of the Kiryu Technical College, Japan, consists of a lengthy and copiously illustrated paper by Tadaroku Ōtashiro on "The Relation between the Photographic Blackening and the Wave-length of Light." The author aims at expressing the blackening as a function of wave-length. For this purpose, different portions of a plate were exposed to different monochromatic lights of equal intensity, and in other cases the wave-length was kept constant and the intensity varied. Ordinary, orthochromatic, panchromatic, and ordinary plates "dyed" (bathed) with solutions of erythrosin, cyanin, and pinacyanol were employed. The author theoretically determines from the photoelectric viewpoint the actual relation between the blackening and the wave-length of the incident light, intensity being constant, and experimentally confirms it. "The general form of the function is quite independent of the kinds of plates, the strength of sensitising solutions, the time of bathing plates in a sensitising solution, the time of washing after bathing, the developers and the temperature during the time of development." The equation includes a "solarisation factor," and it is shown that there are "two maxima and one minimum effect of blackening on the continuous exposure to the most effective light . . . and the first maximum corresponds to the end of the period of over-exposure defined by Hurter and Driffield." He shows that there is a definite relation between the blackening and the strength of any dye solution. The author comes to other interesting conclusions, especially with regard to multiple exposures, and concludes "that the change when a plate has been acted on by white light should be essentially the same as that when the plate has been exposed to the most effective monochromatic rays of light."

Analysis of Coal.—The Fuel Research Board of the Department of Scientific and Industrial Research has issued through H.M. Stationery Office (1*s*. 6*d*. net), Pamphlet No. 2 on the "Physical and Chemical Survey of the National Coal Resources," consisting of an interim report on "Methods of Analysis of Coal." The Board has always had in view the physical and chemical survey of coal seams in the different mining areas—a task of great magnitude—and the policy pursued has been to encourage the formation of local committees of persons interested in the different coal fields to which the execution of the survey could be delegated. The results of such a survey would be greatly depreciated in value unless unity of analytical procedure were ensured, and accordingly the Board asked a committee on sampling and analysis of coal, presided over by Prof. T. Gray, to tabulate a scheme of coal analysis which could be uniformly adopted in the survey. This pamphlet records their efforts. The importance is even wider, for most commercial coal testing is confined to the proximate analysis—essentially empirical and demanding uniformity of practice if discrepant analyses and commercial friction are to be avoided. There is no doubt as to the value of the report in this direction. Although nothing of the kind has been done previously in Great Britain, the field has already been tilled by American fuel chemists—so well that in many cases the committee has been able to adopt their specification without serious modification. This applies particularly to the proximate analysis, and it is likely for that reason that many will find no difficulty in adopting the committee's recommendation. Several special and less common methods of coal assay and analysis are included which will add to the usefulness of the pamphlet. A statement of the permissible analytical error is sometimes given, and forms a welcome inclusion. In suggesting a form of report the committee employs a precision of stating results not quite consistent with its own tolerances. The important question of sampling is reserved to a second report.

School Geography.[1]

Among the valuable reports presented by committees of the British Association at the recent meeting at Liverpool was one on the teaching of geography. The committee included representatives of the two Sections of Geography and Educational Science, and was appointed to formulate suggestions for a syllabus for the teaching of geography both to matriculation standard and in advanced courses, to report upon the present position of the geographical training of teachers and to make recommendations thereon, and to report upon the practical working of Regulations issued by the Board of Education affecting the position of geography in training colleges and secondary schools.

That such a task was pressing, all who have the interests of secondary education at heart will readily admit, and it was well that such an independent body as a committee of the British Association should have undertaken it, for the report shows that the matter demanded urgent consideration and considered judgment. The committee consulted with heads of schools, teachers of geography, examination boards, and universities, and the report is full of suggestions expressed with marked clarity and cogency.

There can be no doubt that a reconstruction of the method and content of geography teaching along the lines of this report is a matter of urgency. The world of to-day is fundamentally different from the world of twenty years ago—or indeed of ten years ago. Life is much more complicated: not only is man more dependent for his social well-being on the activities of a vastly wider world, but his immediate social environment is a complex that requires for its comprehension a degree of reasoning power and scientific knowledge that the school curriculum of a few decades back failed to give. The study of classical literature may give one a deep insight into the life and thought of intellectual giants of the past, but the most pressing need of modern education is a curriculum that will bring before the pupil vividly, and in logical order, the controlling factors that are shaping and giving colour to the social world in which he has to live, and enable him to understand his environment, adjust himself to it, and adjust it to himself. "Geography as ordinarily understood," says the Report, "deals with the world of to-day: it occupies a special position in the study of human conditions at present obtaining in the various parts of the earth and the tendency of the changes taking place therein." Geography, therefore, must take a prominent position in any modern scheme of humane studies. Huxley spoke and wrote strenuously for a curriculum more fitted to help a citizen through the increasingly complicated life that he had to lead (it was the age of scientific discoveries), and his arguments hold with increased force to-day.

One charge that has been laid at the door of modern education is that the teaching of science, history, etc., is formal rather than human, that the courses maintain steady paths parallel to each other without converging at any point. What is wanted is a "core" subject which draws on the others for its facts, co-ordinates them, and thus, by correlation, gives each a fuller and richer meaning. This report shows how geography can be made to function as this core subject. Mackinder and Herbertson at Oxford, Lyde and Chisholm in London, demonstrated this new conception of geography twenty years ago, and the rapid strides made in recent years in the methods of geography teaching in secondary schools are due to the efforts of the young teachers whom they primarily inspired.

At the present time geography takes a place in the school curriculum on a level with history, and below that of classics, French, mathematics, and science. That more sympathy with the subject is not forthcoming is due, first, to the lack of trained geography teachers, whose enthusiasm and knowledge would compel greater recognition, and, secondly, to the fact that the inspectors of the Board of Education, being mainly interested in other subjects, have hitherto attached small importance to it.

For the lack of trained geography teachers one has to blame the Board of Education and the universities jointly. If the former had recognised the importance of the subject earlier and pressed for skilled geography teachers, it is reasonable to assume that the Universities would have established honours schools in geography, as they did, in like circumstances, in science and history; conversely, if the universities had taken the lead, the Board of Education would have been forced to give greater recognition to the subject, just as it has recently been induced to institute a geography group in advanced courses for secondary schools, through pressure from the council of the British Association.

That the geography group will justify its inclusion in the advanced course there can be no doubt, and when one considers the comparative merits of other subjects as a training for life and citizenship one wonders why its inclusion has been so long delayed. At the moment, however, the total lack of geographical scholarships at the universities is a factor that will operate very strongly against a pupil's choice of geography in the advanced course. A boy destined for a professional career to whom the other subject groups are perhaps more useful as a preliminary training for his university course, will naturally make his selection from them, the quantity of scholarships being a strong determining factor. The British Association might usefully direct its attention to this aspect of the problem.

On the other hand, the geography group presents attractions that should more than counterbalance this drawback. To begin with, parents whose boys are destined for city careers—clerical, secretarial, or commercial—have hitherto failed to see, and very naturally, how a two-years post-matriculation course in one of the existing subject-groups can help their sons in a degree at all commensurate with the expenditure of time and money involved. Added to that, many firms prefer to engage youths at the earlier age, and parents with sons of eighteen years have a difficulty in placing them. There is, however, a growing demand for young men who can produce evidence of specialised training for business life—a training, by the way, which so far only private institutions have endeavoured to provide, albeit fairly adequately and remuneratively. In the syllabuses for these examinations—Institute of Secretaries, etc.—geography occupies an important position, and it is also an important subject-group in the course for the B.Com. and B.Sc. (Econ.) degrees which represent the hall-mark, as it were, of vocational training for business life. For these examinations, the geography group is clearly the most useful, and cannot fail to prove attractive.

On turning to the Report itself one has to admit that

[1] Geography Teaching. Report of Committee (Prof. T. P. Nunn, Chairman; Mr. W. H. Barker, Secretary; Prof. H. J. Fleure, Mr. C. J. R Howarth, Sir H. J. Mackinder, Prof. J. L. Myres, and Prof. J. F. Unstead, from Section E; Mr. G. H. J. Adlam, Mr. D. Berridge, Mr. C. E. Browne, Sir Richard Gregory, Mr. E. Sharwood Smith, Mr. E. R. Thomas, and Miss P. Wright, from Section L) (British Association, Burlington House, London, W.1.) Price 1s.; 10s. per doz.; 4l. per 100.

any attempt to summarise it must meet with failure: every aspect of the subject is dealt with in all its bearings, and there is scarcely a redundant word. The chapter on the aim and function of geography is particularly illuminating. Stress is laid on the fact that school geography must be the geography of geographers: not the mere learning of geographical data and results, but a training in the geographer's characteristic methods and principles of interpretation, and an assimilation of his characteristic point of view. This, we consider, is a most important statement, and postulates a trained geographer for the success of any geographical scheme.

Proceeding, the Report deals with the stages of school life, and outlines the principles which should guide in the formation of a syllabus of geographical instruction in secondary schools: a detailed syllabus for each year is appended. Stress is laid on the necessity of proceeding psychologically with young children and of adopting a logical order only as riper years are gradually reached. An outline scheme for each stage, including the advanced course, is given, and apart from its merits as a scheme it possesses special value for the teacher because the underlying aim of each step is made abundantly clear. Great importance is attached throughout to the value of direct observational work and to the construction and interpretation of maps and charts. "One important value of geography in education is the opportunity it gives to express thought in diagram and sketch no less than in words." This sentence should be constantly in the mind of every geography teacher. A highly controversial dictum is that formal lessons in physical geography should not precede the advanced course: incidental teaching of most subjects is apt to be disjointed and incoherent, and the experience of many examiners at matriculation proves that geography is no exception to the rule.

The suggestions for a scheme of study in the advanced courses are excellent. Emphasis is laid on the economic conditions of the modern world, and it is suggested that a small area be selected for comprehensive analysis and synthesis. Correlation of the subsidiary subjects is of course taken for granted.

The chapter on the relation of geography to science and history cannot fail to impress upon the most uninformed reader what a tremendous range of knowledge, not only of topographical facts, but of such allied subjects as physics, geology, botany, biology, history, and economics, is demanded of the geography teacher called upon to carry out such a modern geography course. It is pointed out that it is not his duty to teach these subjects; nevertheless, to correlate them he must know them. The Report proceeds to summarise the facilities offered at the universities for the training of geography teachers. Practically all the universities have established honours schools of geography—mostly in the Faculty of Arts—and there is general agreement that the subject of study should include geology, history, and political economy at least to intermediate standard. The number of trained geographers leaving the universities is steadily increasing, and "the result," to quote the Report, "undoubtedly will be not only a more thorough and scientific study of the subject, but a general increase of accurate knowledge of the Empire and the rest of the world, which will affect the everyday life of the community through its economic and political relationships with other countries."

J. Martin.

Transport and its Indebtedness to Science.

In the Engineering Section of the British Association at Liverpool, one whole morning was devoted to the subject of transport, the other sessions being occupied by papers—many of great interest—on very diverse branches of engineering. The president of the Section, Sir Henry Fowler, was chief mechanical engineer of the Midland Railway, and he took as the subject of his address "Transport and its Indebtedness to Science." extracts from which were published in Nature of September 29, p. 474. He was followed by Mr. A. E. Berriman, the chief engineer of the Daimler Co.; Col. O'Brien, the electrical engineer of the L.M.S. Railway; Major-General Sir Sefton Brancker, of the Air Force; and Mr. A. T. Wall, of Messrs. Wall, Maas and Co., naval architects, of Liverpool.

Each speaker dealt with the branch of the subject with which he was specially identified. As the president pointed out, there is probably no city in the world more dependent on transport than Liverpool, and no city which has done such pioneer service in its development. Whether one considers canals, steam railways, electric railways, or motor traffic, one finds that Liverpool was in the forefront of development, and it was a happy thought of the president, a non-academic engineer, engaged in practice, to take as his thesis that progress in all means of transport has been based upon scientific investigation, to predict that this will be even more marked in the future, to insist on the interdependence of science and engineering, and the necessity for the terms scientific and practical being synonymous. In concluding his address Sir Henry said that "one would like to feel that the meetings of the British Association were more generally used as the occasion on which the scientist and the engineer would meet in larger numbers."

Mr. Berriman gave a very valuable review of the position of road transport. He was somewhat scathing in his criticism of the railway companies' lack of faith in the railway principle, as shown by their proposal to operate their own road vehicles for through traffic. He maintained that, since the tractive effort on rails is only 5 lb. per ton against 60 lb. per ton on average roads, it is technically a sheer waste of energy to transport by road between distant points that are rail-connected. Mr. Berriman also dealt with the question of traffic regulation, and maintained that the warning signs on roads have been put up on a wrong principle and are consequently largely disregarded; in his view, every crossing should have a primary and a secondary stream of traffic, the former having priority and not being expected to slow down; drivers on the secondary roads would be warned to go dead slow on approaching a crossing.

Col. O'Brien's paper, as was to be expected, dealt largely with the question of electrification, which is really an economic one; there are no engineering difficulties. "A very slight lowering of rates of interest and in the price of the material required for such electrification is likely to produce a very considerable development in future." "There is no doubt that the electrification of any main line containing gradients of 1 in 300 or greater and averaging over 2 trains per hour in either direction would at least involve no loss of any kind to the company, while the indirect advantage to both the railway company and the electrical industry of the country would be very large."

Sir Sefton Brancker's breezy optimism with regard to aerial transport caused some amusement. He was fortunate in delivering his paper before the news came

through of the London-Manchester air-mail disaster, which occurred on the same day, more especially as he emphasised the safety, comfort, and exhilaration of flying. Under present conditions, he stated, the cost per passenger-mile could not be reduced below 8½ pence, whilst the highest fare obtainable was 6 pence per mile, leaving 2½ pence to be covered by subsidy. Freight costs per ton-mile he placed at 3*s.* 6*d.* to 5*s.* The only difficulty in the way of development, beyond the economic one, is the difficulty and danger of flying under conditions of poor visibility. The economic range for airships is more than 1000 miles, whilst that of aeroplanes is rarely more than 300 miles, hence the two are complementary and should develop together.

In dealing with sea transport, Mr. Wall emphasised the need for scientific research, especially in metallurgy, but he stated that a very hopeful sign for future progress is to be found in the increasing number of scientific experiments on a large scale carried out by shipbuilders and engineers and sometimes by shipowners. "Experience may, and often does, precede the scientific treatment, but progress is much more rapid when science is used to guide experience."

The Future of the Imperial Institute.

A WHITE Paper (Cmd. 1997), issued on November 22, contains the report of the Committee appointed by the Secretary of State for the Colonies to inquire into the affairs of the Imperial Institute, consequent upon financial difficulties, and also the resolutions passed by the Imperial Economic Conference on considering that report. An article commenting upon the recently published report on the work of the Institute appeared in NATURE of November 10, p. 677.

The Committee considers that the collection and dissemination of information in regard to raw materials is the most important work carried out by the Imperial Institute at the present time. It recommends that the Imperial Institute should continue to function at South Kensington as a clearing-house of intelligence and information, equipped with laboratories for the preliminary analysis and investigation of raw materials, and maintaining sample rooms illustrative of Empire raw materials. The collections in the Public Exhibition Galleries, although recognised as possessing educational value, are not regarded as essential to the future work of the Institute, and it is recommended that the collections be discontinued, though the Committee is by no means unanimous on this point, as is shown by a note appended to the report. It is proposed, however, that a representative selection of Empire products should be made for the purpose of a travelling exhibition of an educational character, and that the organisation of travelling exhibitions of the staple products of the Colonies and Protectorates in appropriate trade centres should be considered.

The Committee proposes reforms in the management of the Institute, suggesting that it should be made responsible to the Department of Overseas Trade. After the completion of these reforms, the Committee recommends the amalgamation of the Imperial Mineral Resources Bureau and the Imperial Institute. The annual expenditure of the reformed Institute (including the Imperial Mineral Resources Bureau) is estimated at about 40,000*l.*, to be provided on a contributory basis. Failing the provision of this sum, which is regarded as a condition precedent to the Committee's recommendations, an alternative scheme is proposed to retain the essential functions of the present Institute, *i.e.* of an intelligence and information bureau.

The Committee expresses appreciation of the valuable services rendered by the Director, Prof. W. R. Dunstan, F.R.S., to the Institute and to the Empire during the long period of his connexion with the Institute, and pays a tribute to the work of the technical staff. Prof. Dunstan was appointed Director in 1903, when he had already been for eight years concerned with the work of the Institute.

The report was submitted by H.M. Government to the Imperial Economic Conference, with the proposal that the main scheme of the Committee should be adopted and the necessary funds guaranteed for a term of years. On the recommendation of a Committee appointed by the Conference, under the chairmanship of Lord Salisbury, the main scheme was adopted, subject to certain modifications not affecting the principles involved.

In the *Times* of November 23 it was announced that, in view of the changes in the constitution of the Imperial Institute which have been decided upon, Prof. W. R. Dunstan will resign the directorship of the Institute next month.

University and Educational Intelligence.

BIRMINGHAM.—Mr. Henry Barber, of Culham Court, Henley-on-Thames, who was formerly a solicitor in Birmingham, has given 20,000*l.* for the endowment of a chair of law in the University.

Mr. H. P. Dean has been appointed assistant lecturer in mechanical engineering, and Mr. M. C. Johnson demonstrator in physics.

It is hoped that Prof. F. C. Lea, who has recently resigned the chair of civil engineering on being appointed head of the Engineering Department of the University of Sheffield, will continue to discharge the duties attaching to the chair for the rest of the current session.

CAMBRIDGE.—The degree of Master of Arts, *honoris causa*, is to be conferred upon Mr. J. B. Buxton, professor of animal pathology.

Prof. T. B. Wood has been reappointed by the University as a Member of the Council of the National Institute of Agricultural Botany.

The Frazer lecture is to be delivered by the Rev. John Roscoe on "Immigrants and their Influence in the Lake Region of Central Africa."

A syndicate has been appointed to obtain plans and estimates for extending the School of Agriculture and constructing a building for the Animal Diseases Institute.

GLASGOW.—Prof. W. J. Goudie, James Watt professor of the theory and practice of heat engines, has given 500*l.* to found an "Agnes Rhind" bursary in memory of his mother, for a third-year student of mechanical engineering who has the best class-record in his subject.

Mr. A. Henderson Bishop and his son have offered to the University, for the new Zoological Museum, the great collection of Coleoptera and Lepidoptera made by his late father, Thomas G. Bishop, of Dalmore, Helensburgh. The collection is contained in 18 cabinets enclosing 700 separate boxes, and numbers some thirty or forty thousand specimens. All are beautifully mounted, labelled, systematically arranged, and in perfect condition. The University has had no difficulty in accepting the splendid gift, with the condition that it shall be accessible for consultation by qualified entomologists, whether they belong to the University or not.

The University Court has submitted for the approval of His Majesty in Council an ordinance establishing the new honours degree of B.Sc. in architecture. The course will extend over four years, and the necessary instruction will be furnished partly within the University, and partly in the School of Architecture, conducted under the joint direction of the Royal Technical College and the Glasgow School of Art.

The Court has also, under powers given by a recent Act of Parliament, approved an ordinance for the superannuation and pensioning, under the Federated System for Universities, of principals and professors hereafter appointed. Principals will retire at seventy and professors at sixty-five. Under the System, years of service as assistant or lecturer, in this or other Universities, may be counted as pensionable service by a professor.

LEEDS.—The Hull Education Committee has decided to make a grant of 800*l.* to the University for the financial year 1924–25.

The title of emeritus professor has been conferred upon Dr. Arthur Smithells, who recently retired from the chair of chemistry, on the grounds of intellectual distinction and of long and meritorious service to the University.

LONDON.—Mr. W. E. Le Gros Clark has been appointed as from Jan. 1, 1924, to the newly instituted readership in anatomy tenable at St. Bartholomew's Hospital Medical College. During 1919–20, Mr. Le Gros Clark was demonstrator in anatomy at St. Thomas's Hospital, and since 1920 has been Principal Medical Officer at Sarawak, Borneo. He has published papers entitled "Series of Ancient Eskimo Skulls," and "On the Pacchionian Bodies."

The following doctorates have been conferred: *D.Sc. in Embryology*, Miss Margaret Tribe, an internal student (University and King's Colleges) for a thesis entitled "The Development of the Hepatic Venous System and the Postcaval Vein in the Marsupialia"; *D.Sc.* (*Economics*), Mr. B. R. Ambedkar, an internal student (London School of Economics), for a thesis entitled "The Problem of the Rupee."

It was resolved that the Physiological Laboratory Library should be kept together as part of the University Library, and be developed in connexion therewith as a memorial to the late Prof. A. D. Waller.

Three free public lectures on "Some Chapters in the Recent Development of the Theory of Electrolytic Dissociation" will be given by Prof. J. N. Brönsted, of the University of Copenhagen, at University College, on December 10, 12, and 14, at 5.30 o'clock.

A course of five free public lectures on "The Influence of Environment on the Life of Bacteria" will be given by Mr. F. W. Twort, at the Royal College of Surgeons of England on December 11 13, 17, 18, and 19, at 4 o'clock.

THE use of mental alertness tests for prospective university and college students is strongly advocated by President W. D. Scott, of North-western University. All institutions of higher education should, he considers, have a "personal director" to perform "an educational function similar to that of the diagnostician in medicine. The giving of mental alertness tests will be as much a matter of the routine with such a director as is the use of the clinical thermometer by the diagnostician in medicine."

THE University College of South Wales and Monmouthshire, Cardiff, issued an appeal in December 1921 for the sum of 250,000*l.* for purposes exclusive of those connected with the development of the Medical School, and particularly with the view of the erection, equipment, and maintenance of laboratories for the Departments of Physics and Chemistry. For these purposes 50,000*l.* had been subscribed by Lord Glanely, and 10,574*l.* by other subscribers, making a total, with accrued interest (12,000*l.*), of 72,574*l.*, part of this sum having been received before the appeal in December 1921 was issued. At a luncheon given by Lord Plymouth on November 20, further gifts amounting to 56,700*l.* were announced, thus bringing the total sum realised by the appeal up to 129,274*l.* It is of interest to note that the foundations of the buildings are just being completed at a cost of approximately 15,000*l.*, and that the cost of the superstructure to accommodate these two departments, based on a recent estimate, is 144,000*l.*; this figure is, of course, exclusive of the cost of equipment and maintenance.

THE second annual report of the Education Statistics branch of the Dominion Bureau of Statistics of Canada gives the total number of university students in 1921–22, excluding preparatory, summer, and other short courses and correspondence courses, as 23,800. Included among these are: undergraduates in arts and pure science, 6859 men and 3872 women; graduates, 712 and 300; medical, 3134 and 154; engineering and applied science, 2513 and 3; music, 278 and 717; theology, 854 and 11. The teaching staffs numbered 3137, including 307 women. The total assets of the universities amounted to 67 million dollars, including endowments, 26 million, land and buildings, 27, and scientific equipment, 5 million. Incomes amounted to $9\frac{1}{2}$ million, and were derived from: investments, $1\frac{1}{2}$ million; government and municipal grants, $4\frac{1}{2}$ million; fees, 2 million; and other sources, $1\frac{1}{2}$ million.

EDUCATIONAL development and scientific research are not figuring largely in the election pledges of the several political parties and the speeches of their leaders, except those of the Labour party, and this party's promises are subject to considerable discount in view of the disproportion between the stupendous cost of carrying out its programme, including "the abolition of the slums," etc., and the resources that would be at the disposal of a Labour party government. This disproportion would necessitate the scrapping of a large part of the programme. The Liberal party manifesto contains on the subject of education only platitudes, but Mr. Asquith promised the Women's National Liberal Federation "smaller classes, provision of free places in secondary schools, State scholarships for universities, more adequate training for teachers," and "the encouragement and fuller development of adult education," while Lord Grey, when speaking on adult education on November 23, is reported to have said, "What was wanted was not State control but State assistance. For the small sum of 500,000*l.* they would get a better return than in any other way." It is part of the Conservative election policy to concentrate attention on the main issues of unemployment and protection, and the party leaders are accordingly saying little about education. Mr. Baldwin's speech of November 19 showed that he is alive to the supreme importance of the evils of juvenile unemployment, but does not suggest that he believes in retention in school as an appropriate remedy at the present time. In his speech at Reading on November 21 he referred to the importance of agricultural research and education as a permanent part of the life of the country, and remarked that the Government, recognising this, has given 1,000,000*l.* for promoting them.

Societies and Academies.

LONDON.

Royal Society, November 22.—F. **Simeon**: The carbon arc spectrum in the extreme ultra-violet—II. The spectrum of the carbon arc in vacuum extends as far in the extreme ultra-violet as that of the spark, with the exception of a very faint line at 360·5 Å, and about 25 lines have been added to the arc spectrum as already recorded. The L series of carbon can be excited by a potential of between 30 and 40 volts. A number of lines in the carbon spectrum are probably true "arc" lines. Providing the grating will give radiation in the short-wave region, the same technique suffices to photograph the spectrum from 1850 Å to 370 Å.—H. J. **Gough** and D. **Hanson**: The behaviour of metals subjected to repeated stresses. The effect of static and alternating stresses on the micro-structure of metals was examined, the main object of the research being to determine whether the crystalline structure of a metal can be affected when subjected to ranges of stress *less* than the limiting range of stress (fatigue range). With "Armco" iron, mild steel, and copper, crystalline "slip" occurs at ranges of stress considerably less than the fatigue range. It is suggested that metals can be "strain-hardened" under the action of alternating stresses, as well as under static stresses; fracture occurs, in a metal subjected to alternating stresses, when a certain limiting strain for the material is exceeded.—W. **Sucksmith** and L. F. **Bates**: On a null method of measuring the gyro-magnetic ratio. A new method is described of determining the gyro-magnetic ratio; as in the ordinary resonance method, the specimen, suspended vertically by a fine wire along the axis of a helix, is magnetised by an alternating current of the same frequency as the natural frequency of the system; but the resulting resonance amplitude is reduced to zero by a series of impulses timed to oppose those due to gyro-magnetic effect. As no measurement of magnetic moment, frequency, or damping is involved, a considerable gain in precision is obtained. The method is independent of time-lag in magnetisation, and so can be applied to Heusler alloys. The following mean values of the ratio obtained for iron, nickel and Heusler alloys were obtained: Iron 0·503; nickel 0·501; Heusler alloys 0·501.—J. H. **Shaxby**: Studies in Brownian movement.—II. The determination of Avogadro's number from observations on bacteria (cocci). A determination of Avogadro's number by measuring the displacements, due to their Brownian movements, of small spheres suspended in water was carried out with cocci. Their surfaces may be supposed to be "wetted" so that there is no slip between the water immediately adjacent and the spheres themselves, and the resistance which might arise from electrical sources depending on slip is avoided. The value of N thus found, from the large number of observations made on *Staphylococcus albus*, is $6{\cdot}08 \times 10^{23}$.—H. **Hartridge** and F. J. W. **Roughton**: The kinetics of Hæmoglobin.—II.—A. F. A. **Young**: The thermionic and photo-electric properties of the electro-positive metals.—O. F. T. **Roberts**: The theoretical scattering of smoke in a turbulent atmosphere.

Zoological Society, November 6.—Sir S. F. Harmer, vice-president, in the chair.—A. **Loveridge**: (1) East African birds (chiefly nesting-habits and endoparasites), collected 1920–1923. (2) East African snakes, collected 1918–1923. (3) East African tortoises, collected 1921–1923, with description of a new species of soft land-tortoise. (4) East African lizards, collected 1920–1923, with descriptions of two new races of *Agama lionotus* Blgr. (5) East African insects, collected 1915–1922.—I. G. S. **Montagu**: On some mammals from Jugo-Slavia.—I. G. S. **Montagu** and Miss Grace **Pickford**: The Guernsey Crocidura.—G. H. **Goldfinch**: Notes on the African crested rat (*Lophiomys imhausi*).—H. G. **Jackson**: A revision of the isopod genus Ligidium Brandt (Crustacea).—S. S. **Flower**: On additions to the snake fauna of Egypt.—S. **Hirst**: On some new or little-known species of Acari.—C. F. **Sonntag**: On the pelvic muscles and generative organs of the male chimpanzee.

Geological Society, November 7.—Prof. A. C. Seward, president, in the chair.—R. W. **Hooley**: On the skeleton of *Iguanodon atherfieldensis* sp. nov., from the Wealden shales of Atherfield (Isle of Wight). The nearly complete specimen was obtained in 1914. There is an essential similarity as regards the relationship of the bones of the skull to the American pre-dentate dinosaurs. Grooves on the premaxillæ prove that the tip of the snout was sheathed in horn. The quadrate bone articulated freely with the squamosal, and there was a fore-and-aft action of the mandible. The tongue must have been extremely narrow, with a broad tip, and prehensile. The neck was habitually flexed, the point of greatest arching being at the ninth cervical. All the pre-sacral vertebræ carry ribs. The sacrum comprises six fused vertebræ. The ossified elements of the left carpus were preserved. The integument was very thin and covered with small tubercles, interspersed with groups of large polygonal plates, as in Trachodon. The estimated length of the skeleton is 6·3 m. (about 21·6 feet). *I. atherfieldensis* is distinct from any known species, and the skull and bones are intermediate in form between that of *I. mantelli* and *I. bernissartensis*.—S. H. **Reynolds**: The igneous rocks of the Tortworth inlier. The igneous rocks occur in two bands, the upper of which is associated with calcareous tuffs containing Silurian fossils and is doubtless lava. The lower band appears to be intrusive. The rocks of the two bands have several features in common. The rocks of the lower band are characterised by the presence of pseudomorphs after olivine, and may be grouped as olivine-enstatite-basalts. Those of the upper band are devoid of olivine, and consist of pyroxene-andesite. They are characterised by the presence of highly corroded xenocrysts of quartz and felspar, and by the occurrence of variolitic and glassy patches in the ground-mass.

Linnean Society, November 15.—Dr. A. B. Rendle, president, in the chair.—E. J. **Salisbury**: The relation of earthworms to soil reaction. Natural undisturbed soils usually show a definite gradient with respect to organic material and acidity, both of which tend to attain a maximum at the surface. Analyses of worm casts show that these have a high organic content indicating their origin from the superficial and most acid layers. Comparison of the hydrogen ion concentration of worm casts and surface soil shows that acid soils tend to be rendered much less acid by passage through the worm. Markedly alkaline soils may similarly be rendered less alkaline. The former action may be attributed to the calciferous glands. The greatest frequency of worms is met with in soils with approximately neutral reaction.—Miss E. M. **Blackwell**: The flora of Solomon's Pools. Solomon's Pools lie about six miles south of Jerusalem, 2616 feet above sea level, in a valley, Wâdy Artâs, which runs east and west between low hills of red-brown ferruginous earth through which limestone bosses project. The pools, three in number, are obviously artificial. The middle and lowest pools have been

cleaned and partly repaired, and pumping plants erected. In July 1923 the uppermost pool had already dried up. The clear water of the pools supported a luxuriant growth of *Chara connivens* in the lowest and *C. contraria* and *C. fragilis* in the middle pool, forming almost a pure society. In the middle pool there was in addition an aquatic grass and a new filamentous algæ, desmids and diatoms. In the lowest, *Potamogeton flabellatus* var. *scoparius* was flowering and fruiting, almost rivalling the Chara for dominance. At the deeper end of the lower pool were tufts of *Riella helicophylla*, their spirally coiled thalli floating out into the water in loose rosettes at a considerable depth. Where the floor of the west side of the lowest pool was exposed on account of the slope, the drying mud was covered with bleached plants of Chara, and growing up through it *Typha latifolia*, *Scirpus maritimus*, *Heleocharis palustris*, and *Euphorbia aleppica*. The flora is similar to that of the "slacks" in the Lancashire sand-dunes. The waters in both cases have a high percentage of dissolved solids, especially chlorides and carbonates.—R. E. **Chapman**: The carbohydrate enzymes of certain Monocotyledons. The material used was the green foliage leaves of the snowdrop, the onion, and the leek, with a starch-forming plant, a common dock, for purposes of comparison. The leaves were air-dried, powdered, and added to dilute solutions of starch, dextrine, maltose, cane sugar, and amygdalin, using qualitative tests and changes in the rotation of polarised light for the detection of hydrolysis. Toluol was used as antiseptic and the solutions incubated at 39° C. The results indicated that of the five carbohydrate enzymes—amylase, dextrinase, maltase, invertase, and emulsin—maltase and emulsin were absent from the snowdrop, dextrinase from the onion, amylase from the leek, but all five were present in the dock. The formation of starch in the parenchyma cells of the three Monocotyledons is thus prevented, because the necessary set of enzymes is incomplete. In certain cases (*e.g.* Galanthus and Narcissus) starch is always present in the guard cells, and prolonged starvation in darkness does not cause the disappearance of this starch. In the snowdrop the adult leaf has starch in the guard cells together probably with diastase but not maltase, so that hydrolysis can proceed only to maltose, and the system, starch $\rightleftarrows$ maltose catalysed by diastase, may be part of the mechanism controlling the opening or closing of the stomata.

Royal Meteorological Society, November 21.—Dr. C. Chree, president, in the chair.—L. F. **Richardson**: Attempts to measure air temperature by shooting spheres upward. Whilst making observations of the upper wind by shooting polished steel spheres upwards in a direction slightly inclined from the vertical so that the wind caused the returning sphere to fall quite close to the gun, the time of absence of the sphere can afford a measure of a mean temperature of the air through which it has passed. The upper air temperature was measured from the mean of six shots with a standard error of 1° C. at sunrise in calms or light winds. On such occasions, there is often a layer of cold stagnant air near the ground, so that the temperature in the Stevenson screen is a poor guide to the temperature at 70 metres. Here the projectile may be useful.—S. N. **Sen**: On the distribution of air density over the globe. Thirteen charts of "isopycnics" or lines of equal air density are drawn depicting the density distribution at the various levels. The air density at the 8 km. level all over the globe is illustrated by the chart for that level. The air density is controlled by temperature up to a height of about 8 km. and by pressure above that level. The name "thermosphere" is proposed to denote the atmospheric shell in which temperature is the controlling factor, and "barosphere" that in which pressure is the controlling factor. On the average, when the temperature is rising in one hemisphere there is a diminution of air density in the thermosphere and an increase in the barosphere, and the effect of diminishing temperature in the other hemisphere is the reverse. These opposite thermometric tendencies create a mechanism for the automatic breaking down of the stratification of the free atmosphere. This mechanism, or the "convective cycle" which is postulated to be established between the North and South poles, also affords a means for the interchange of air between the two hemispheres.

PARIS.

Academy of Sciences, November 5.—M. Albin Haller in the chair.—The president announced the death of M. Arnaud de Gramont, member of the section of free Academicians.—G. **Ferrie**, R. **Jouaust**, and R. **Mesny**: The amplification of the current from photo-electric cells and its applications. The currents produced by photo-electric cells are very small, of the order of 10^{-10} amperes. These can be magnified by the use of a three-electrode lamp as a relay without inertia. A magnification of 1000 has been obtained with a lamp of the dimensions of an ordinary receiving lamp; with an emission lamp of 50 watts working under 1000 volts, an amplification of 10,000 was obtained. A more complicated method, based on the conversion of the photo-electric current into an alternating current and transforming up, is described: this permits of amplifications up to the order of 10^6.—J. **Costantin**: The Pleurotus of the blue thistle of the Vanoise.—L. **Maquenne**: The theory of chlorophyll synthesis. A discussion of the Boussingault-Bæyer theory of chlorophyll synthesis of the carbohydrates. An alternative hypothesis is put forward in which quadrivalent magnesium is assumed. Carbonic acid is assumed to be taken up by direct addition to the : N – Mg – N : groups; the assumption of the intermediate formation of formaldehyde is unnecessary.—Andre **Bloch**: Paratactic congruences and Dupin's cyclid.—M. **Angelesco**: The generating functions of Hermite polynomials.—Emile **Borel**: Remarks on the preceding communication.—J. **Wolff**: Non-measurable ensembles.—N. **Gunther**: A problem of hydrodynamics.—A. **Foch**: The dynamicable similitude of an aspiration tube and its model. A discussion of the application of aspiration tubes to turbines, with especial consideration to the formulæ governing the relations between models and the full-size turbine.—Louis **Breguet**: The calculation of the weight of combustible consumed by an aeroplane during ascent. The formulæ for the effective range of an aeroplane have been worked out on the assumption of horizontal flight. Modifications are introduced into the Rateau equation showing the variations in petrol consumption during ascent and descent.—C. **Chéneveau** and J. **Callame**: A micropalmer. A description, with diagram, of an instrument designed for measuring the thickness of thin sheets or plates of rubber or other plastic material, with an accuracy of 0·001 mm.—E. **Brylinski**. Michelson's experiment.—Mlle. Berthe **Perrette**: An arrangement of the electric arc in a vacuum allowing the spectra of metals to be obtained with very small quantities of material. The cathode is formed of tungsten (or tungsten-thorium) wire, and the anode of a tungsten plate in which a small cavity is drilled to hold the material. The cathode is raised to a high temperature by a current of 4 to 5 amperes from accumulators.

The voltage between anode and cathode is 110 volts, the whole working in a vacuum of about 0·002 mm. of mercury. The lines of the spectrum given by this apparatus are very fine and give high orders of interference, and less than 0·05 gm. of material can be taken.—N. **Perrokis**: Study on the stability, in the presence of water, of a certain number of binary mixtures. Two groups of pairs of miscible liquids were studied: ethyl alcohol with phenyl ether, benzene, *o*-cresol, phenol; benzene, with various alcohols. The figure determined was the quantity of water necessary to produce two layers when added to 100 gm. of the binary mixture. Some results are given in a diagram.—N. D. **Zelinsky**: The polymerisation of acetylene by contact.—B. Darder **Pericás**: The tectonic of the neighbourhood of Sineu and of Ping de Sant Onafre (Island of Majorca).—Jules **Wolff**: The conditions favourable or prejudicial to the germination of the seeds of orchids and to the development of the seedlings. The seeds of the orchid can be germinated aseptically in a rich medium, and in the absence of fungi. The seedling can then be planted out on mycelium, and symbiosis is established normally. The presence of the fungus at the commencement of the germination is not only unnecessary, but may prove injurious to the seedlings.—J. **Dauvergne** and Mlle. **Weil**: The culture of plants in a sterile liquid medium. A development of Mazé method, the seeds being supported on perforated aluminium plates.—C. **Fromageot**: Assimilation in the green cells and the structure of the protoplasm.—Lucien **Daniel** and Jean **Ripert**: Researches on the variations of chemical action in grafted plants.—A. **Maige**: The metabolism of the sugars in the cell and amylogenesis. It results from the experiments described that even in cells where amylogenesis requires only a very low concentration in sugar, the essential phenomena of cellular metabolism which assure the continuity of life and growth of the living material may be effected at still lower concentrations.—**Chavastelon** and J. **Luquet**: Contribution to the study of the edaphic conditions of the pastoral associations in the massif of Mont-Dore.—Emile F. **Terroine**, R. **Bonnet**, and P. H. **Joëssel**: The composition of seeds and yield of energy in germination.—Mme. L. **Randoin** and H. **Simonnet**: The influence of the nature and quantity of the glucides present in a ration deprived of factor B on the precocity of appearance of the accidents of polyneuritis in birds. In constructing an artificial diet for experiments on diet deficiency, it is very important to take into account the digestive utilisation of each of the food materials composing the diet. The experiments give some support to the idea that the magnitude of the factor B requirement is not absolute but is relative and in direct relation with the degree of utilisation of one or several elements of a ration, and, in particular, with the quantity of sugars assimilated.—Paul **Voukassovitch**: The biology of two parasitic Hymenoptera of Pyralis of the vine.—Marc **Bridel** and Jean **Charpentier**: The biochemical characterisation of galactose in a mixture containing galactose and arabinose. Galactose can be detected in the presence of arabinose, by the action of emulsin in 70 per cent. alcoholic solution. The β-ethylgalactoside can be obtained in the crystalline state, suitable for identification.—André **Lwoff**: A new free ciliated Infusorian, *Stephanopogon Mesnili*. Its taxonomic importance.—Mlle. M. **Gauthier**: The development of the egg and embryo of Cyathocephalus, a parasite of the trout.—Henri **Stassano**: The double rôle of the heating plates in apparatus for the sterilisation of liquids in continuous circulation.

Washington, D.C.

National Academy of Sciences (Proc., Vol. 9, No. 10, October).—L. B. **Loeb**: The mobilities of electrons in air. The mobilities of electrons in air at pressures of 41, 51·5, 60, 66·5, and 92 mm. of mercury were measured in an ion chamber. A constant field superposed on the actuating alternating field was used to neutralise the field produced by the accumulation of ions. Plotting mobility constant (mobility reduced to atmospheric pressure) against critical voltage (static voltmeter) minus retarding potential, curves are obtained showing breaks probably due to attachment of electrons to molecules. Expressions are given for the mobility constants for the distance separating the plates in the ion chamber (1·955 cm.).—P. W. **Bridgman**: The thermal conductivity of liquids. A radial flow apparatus with the liquid between two concentric metal cylinders was used. The inner cylinder was the source of heat, and conductivities were measured at 30° C. and 75° C., and at atmospheric pressure, 6000 kg./cm.^{2} and 12,000 kg./cm.^{2} pressures. Water and fourteen organic liquids were used. Conductivity decreases with rise of temperature, at atmospheric pressure, except for water. At constant temperature, it rises with increasing pressure; at 12,000 kg./cm.^{2}, the increase is from 1·5 to 2·7 fold, the more compressible liquids showing the greater increase. The absolute conductivities at 30° C. range from 0·000505 (methyl alcohol) to 0·000265 (ethyl iodide); for water the value given is 0·00144. A formula connecting the conductivity, gas constant, velocity of sound in the liquid, and the mean distance of separation of the centres of the molecules of the liquid, is derived. The high value for water is referred to its low compressibility and the closeness of the centres of its molecules.—E. S. **King**: (1) Photovisual magnitudes of one hundred bright stars. The Draper 8-inch refractor was used and Cramer Isochromatic Instantaneous plates with a yellow filter. All the plates were taken 1·25 cm. or more outside the focus. Results for A0 stars agree with the photometric magnitudes. In general, the photovisual colour index is greater than the visual or photometric index. (2) Revised magnitudes and colour indices of the planets (*v.* Nature, November 24, p. 769).—R. H. **Bowen**: The origin of secretory granules. Nassonov, working on Salamander glands, showed that early secretory granules are associated with the Golgi apparatus of cells and afterwards have caps or girdles of Golgi material. These results are confirmed. It is suggested that the acrosome of the animal sperm, which arises as a vesicle in close connexion with the Golgi apparatus, and from which the Golgi apparatus is finally separated, is a secretory granule applied to the head of the mature sperm, whence its substance may be released at fertilisation. Referred to other gland cells, the hypothesis suggests that there is direct relation between the Golgi cells and chemical synthesis, and in particular enzyme formation.—R. R. **Huestis**: The heredity of microscopic hair characters in Peromyscus. Two geographic races (coast- and desert-race) of two species of deer-mouse were used. Each coast-race differed from the corresponding desert-race in much the same way. It is concluded that the differences observed between contrasted races have been evolved in the wild state, and some at least are the effect of environment. The results indicate Mendelian inheritance of multiple factors.—C. G. **Abbot**: Preliminary note on the variation of the sun's visible features associated with variations of solar radiation (*v.* Nature, November 17, p. 738).

Official Publications Received.

Department of Commerce: Bureau of Standards. Scientific Papers of the Bureau of Standards, No. 475: Visibility of Radiant Energy. By K. S. Gibson and E. P. T. Tyndall. Pp. 131-191. 15 cents. Technologic Papers of the Bureau of Standards, No. 242: Detector for Water Vapor in Closed Pipes. By E. R. Weaver and P. G. Ledig. Pp. 637-644. 5 cents. (Washington: Government Printing Office.)

Department of the Interior: Bureau of Education. Bulletin, 1923, No. 45: Work of the Bureau of Education for the Natives of Alaska. By William Hamilton. Pp. 4. (Washington: Government Printing Office.) 5 cents.

G. van de Sande Bakhuyzen. Pp. 63. Deel 14, Stuk 2: Dessins de la voie lactée faites à Athènes par J. Fr. Julius Schmidt dans les années 1864-1876. Pp. 8+4 plates. (Haarlem: Joh. Enschede en Zonen.)

Marconi's Wireless Telegraph Company, Ltd. Report of the Directors and Statement of Accounts for the Year ended 31st December, 1922, to be presented at the Annual General Meeting of the Company, to be held at the Connaught Rooms, Great Queen Street, Kingsway, London, W.C.2, on Monday, the 3rd December, 1923, at 12 o'clock noon. Pp. 12. (London: Marconi House, Strand.)

Diary of Societies.

SATURDAY, DECEMBER 1.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 8.—F. R. S. Balfour: Trees and Flowers of the North-West Pacific Coast.

MONDAY, DECEMBER 3.

ROYAL INSTITUTION, at 5.—General Meeting.

SOCIETY OF ENGINEERS, INC. (at Geological Society), at 5.30.—J. W. Gordon: Railway Surveying by Photography.

ROYAL SOCIETY OF MEDICINE, at 5.30.—Dr. Strandberg: Treatment of Tuberculosis of the Nose and Throat by Finsen Light Baths: Results.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—C. M. R. Balbi and others: Discussion on Electrical Apparatus for the Deaf.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Dr. Dorothy Wrinch-Nicholson: Some Aspects of Scientific Method.

ROYAL SOCIETY OF ARTS, at 8.—Prof. A. F. Barker: Recent Progress in the Wool Industries (Cantor Lecture) (1).

INSTITUTION OF THE RUBBER INDUSTRY (London Section) (at Engineers' Club, Coventry Street), at 8.—Major V. Lefebure: Accelerators.

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—J. Allen Howe: The Use and Preservation of Building Stone.—J. J. Fox and T. W. Harrison: The Chemical Aspects of Building-Stone Decay.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Sir Charles Bell: A Year in Lhasa.

ROYAL SOCIETY OF MEDICINE (Tropical Diseases and Parasitology Section), at 8.30.—Sir Leonard Rogers and others: Discussion on Sprue and Cœliac Disease.

TUESDAY, DECEMBER 4.

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—J. H. Anderson: Spontaneous Ignition of Coal.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—H. Dennis Taylor: The Future of the Cinema; and Photography as an Extension of Vision. (Annual Traill-Taylor Memorial Lecture.)

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—H. Balfour: Observations on the Technology of the Nagas of Eastern Assam.

RÖNTGEN SOCIETY (at British Institute of Radiology, 32 Welbeck Street), at 8.15.—Dr. L. G. Heilbron: Modern Radiographical Technique.

WEDNESDAY, DECEMBER 5.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—D. J. Farquharson: The Geology of Southern Guernsey.—C. W. Osman: The Geology of the Northern Border of Dartmoor, between Whiddon Down and Butterdon Down.

ROYAL SOCIETY OF MEDICINE (Surgery Section), at 5.30.—Pathological and Clinical Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—L. B. Turner: The Relation between Damping and Speed in Wireless Reception.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS, INC. (at Engineers' Club), at 7.—A. J. Assheton: Vacuum Steam Heating.

ROYAL MICROSCOPICAL SOCIETY (Biological Section), at 7.30.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—H. Toms: Crystalline Bromides of Linseed Oil.—M. S. Salamon: The Plea for Standardisation.—H. T. S. Britton: Note on the Estimation of Chromium.—R. L. Andrew: The Colorimetric Estimation of Lead in Cream of Tartar.

ROYAL SOCIETY OF ARTS, at 8.—Dr. A. W. Hill: The Work of the Royal Botanic Gardens, Kew.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

THURSDAY, DECEMBER 6.

ROYAL SOCIETY, at 4.30.—E. G. T. Liddell and Sir Charles Sherrington: Recruitment Type of Reflexes.—G. S. Carter: The Structure and Movements of the Latero-Frontal Cilia of the Gills of Mytilus.—*To be read in title only*:—V. B. Wigglesworth and C. E. Woodrow: The Relation between the Phosphate in Blood and Urine.—J. B. S. Haldane, V. B. Wigglesworth, and C. E. Woodrow: (*a*) The Effect of Reaction Changes on Human Inorganic Metabolism; (*b*) The Effect of Reaction Changes on Human Carbohydrate and Oxygen Metabolism.—J. A. Campbell: Concerning the Influence of Atmospheric Conditions upon the Pulse Rate and "Oxygen-Debt" after Running.—J. Gray: The Mechanism of Ciliary Movement. IV. The Relation of Ciliary Activity to Oxygen Consumption.

ROYAL SOCIETY OF MEDICINE, at 5.30.—Sir Jagadis C. Bose: Assimilation and Circulation in Plants.

NEWCOMEN SOCIETY (Annual General Meeting) (in Room 13, Caxton Hall), at 5.30.—I. B. Hart: The Dynamics of Leonardo da Vinci.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—L. Brooks: The Beginnings of Geographical Teaching.

CHEMICAL SOCIETY, at 8.—C. K. Ingold: The Additive Formation of Four-membered rings. Part III. A System of Nomenclature for Heterocyclic Four-membered Rings and the Formation and Properties of some Derivatives of β-Methylenedi-imineoxide.—H. J. S. Sand and E. J. Weeks: The Dependence of Polarisation-Overvoltage on Hydroxyl and Hydrogen Ion Concentration. Part I. Polarisation-Overvoltage of an Antimony Cathode in Aqueous Alkaline Solution.—H. King: Stereoisomerism and Local Anæsthetic Action in the β-Eucaine Group. Resolution of β- and Iso-β-Eucaine.—A. Green: β-Alizarin. An Isomeric Form of Alizarin.—O. L. Brady and F. P. Dunn: The Isomerism of the Oximes. Part XV. The Supposed Fourth Benzildioxime.—W. E. Garner and F. C. Randall: The Alternation in the Heats of Crystallisation of the Normal Monobasic Fatty Acids.

FRIDAY, DECEMBER 7.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—W. Foster: The Archives of the Honourable East India Company (Sir George Birdwood Memorial Lecture).

ROYAL ASTRONOMICAL SOCIETY, at 5.—Geophysical Discussion: Gravity Deflections in Great Britain and the Geoid. Chairman, Col. E. M. Jack. Opener, Sir C. F. Close. Other speakers, H. L. P. Jolly, A. R. Hinks, Col. H. L. Crosthwait, Dr. J. W. Evans, and Capt. G. T. McCaw.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: The Life and Times of William Clift, First Conservator (Thomas Vicary Lecture).

PHILOLOGICAL SOCIETY (at University College), at 8.—C. R. Enock: Euphratean Origin of Man, Language, and Place-Names.

ROYAL SOCIETY OF MEDICINE (Surgery, Ophthalmology, Otology, Laryngology, Odontology, and Anæsthetics Sections), at 8.30.—Dr. P. Watson-Williams and others: Discussion on The Comparative Value of Cocaine Substitutes.

PUBLIC LECTURES.

SATURDAY, DECEMBER 1.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. N. Milligan: The Natural History of Dragons.

BIRKBECK COLLEGE, at 6.—Dr. F. H. Hayward: Celebration of The Geologist.

MONDAY, DECEMBER 3.

LONDON HOSPITAL MEDICAL COLLEGE, at 4.15.—Dr. Gordon Holmes: Some Symptoms of Cerebral Irritation (Schorstein Memorial Lecture).

TUESDAY, DECEMBER 4.

KING'S COLLEGE, at 5.30.—Miss Hilda D. Oakeley: The Roots of Early Greek Philosophy: (2) Scientific.

WEDNESDAY, DECEMBER 5.

UNIVERSITY COLLEGE, at 5.30.—W. C. B. Sayers: Library Classification in Modern Life.

THURSDAY, DECEMBER 6.

KING'S COLLEGE, at 5.30.—Dr. A. R. Pastor: Spain and Europe (League of Nations Union Lecture).

FRIDAY, DECEMBER 7.

UNIVERSITY COLLEGE, at 5.15.—Prof. Karl Pearson: Eugenics.

SATURDAY, DECEMBER 8.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. E. M. Delf: Sunlight and Life.

SATURDAY, DECEMBER 8, 1923.

Research Professorships.

THIS year's anniversary meeting of the Royal Society, an account of which is given elsewhere in the present issue of NATURE, was the first since Sir Alfred Yarrow made his munificent gift of 100,000*l.* to the Society in February last, "to mark my sense of the value of research to the community." The meeting was, therefore, appropriately devoted in the main to an account by the president, Sir Charles Sherrington, of the purposes to which this and other large benefactions are to be used. The essential aim of the Society is the creation of new knowledge by scientific inquiry, and the new professorships which have been founded through recent gifts will promote and facilitate this intention.

Lord Justice Warrington, in proposing the toast of the Royal Society at the anniversary dinner at the Hotel Victoria, drew a parallel between the proceedings in a court of law and those in a laboratory of science. In both cases evidence is elicited with the object of arriving at a correct judgment upon it, and endeavours are made by cross-examination to test the truth of the testimony given. The suggestion that it is much easier to get truthful response by appropriate stimulus in Nature than it is from human witnesses is, however, one to which scientific investigators may hesitate to subscribe. Nature can never be trusted to give a direct answer to a question if she can avoid it, and will deceive the inquirer if she can. Also, while the laws of civil life can be broken, there must be no exception to a law of Nature, which is simply a description of certain relationships expressed in words or in mathematical terms. When observations prove such a relationship to be incorrect, then the law has to be modified or abandoned to take the new facts into consideration. Moreover, while in civil law precedent is all-powerful, in science it counts, or should count, for nothing.

The motto of the Royal Society, *Nullius in verba*, adapted from Horace's *Nullius addictus iurare in verba magistra*—not bound to swear to the words of any master—is an expression of the revolt against authority which was in the ascendant when the Society was founded. Long before the reaction against the Aristotelian method and doctrine which Francis Bacon represented with such virulence and bitterness, Roger Bacon had claimed for himself and his contemporaries the liberty of independent inquiry. At the Renaissance, impatience with the constant appeal to the authority of Aristotle was widespread among all who were foremost in the revival either of science or of letters, and what Francis Bacon did in his "Novum Organum"

was to embody prevailing views and propound a new philosophy.

In his "New Atlantis," Bacon planned a palace of invention, a great temple of science, where the pursuit of natural knowledge in all its branches was to be organised on principles of the highest efficiency. His Solomon's House was regarded as a prophetic scheme of the Royal Society, and the story of it as a vision of the practical results to be anticipated from diligent and systematic study of Nature. By the establishment of research professorships the Society is directly creating a body of experimenters on this design, which was that originally conceived for it, in addition to being "the Store-House of Natural Philosophy."

When a research professor is already associated with a university or other teaching institution, the appointment will mean that the professor will be relieved of his lectures and other duties of instruction of students. The amount of time which this work and participation in administrative affairs demand differs in different centres, but in most cases it leaves little opportunity for sustained attention to research problems. Prof. Alfred Fowler, who has been appointed to one of the Yarrow research fellowships, is professor of astrophysics at the Imperial College of Science and Technology, London; and though he has not perhaps been so overwhelmed with instructional responsibilities as are many professors in provincial universities, yet much of his time has had to be given to them, and the time left for his experimental investigations has been correspondingly limited.

Prof. Fowler's main contributions to astronomical physics are described in Sir Charles Sherrington's presidential address. The modern phase of his work may be said to have begun in the year 1912, when he succeeded in obtaining, from a tube containing helium and hydrogen, certain series of lines, some of which had previously been observed only in the spectra of a few stars or had been predicted on theoretical grounds as forming part of the spectrum of hydrogen. Shortly afterwards, Bohr published his now famous theory of the origin of spectra, in the light of which the series detected by Fowler were seen to be due to helium, and with this discovery began the close association between the experimental work of Fowler and the theoretical work of Bohr which has led to such remarkable advances in recent years.

In the Bakerian Lecture of 1914, Fowler showed that the enhanced lines of the alkaline earth metals formed series precisely similar to those of the "arc" lines, except that the series constant had four times its normal value. According to Bohr's theory, this meant that the enhanced lines were produced by atoms which had lost one electron, and the generalisation at once followed that the atoms of any element which had lost one electron would yield series having 4N in place of the Rydberg constant, N. Carrying the process still further, Fowler has recently shown that the spectrum of silicon contains series characterised by a constant 16N, indicating the existence of radiating atoms which have lost three electrons.

A great deal of Prof. Fowler's time has been devoted to the training of research students, whose work testifies to the encouragement and help they have received from him. Curtis's determination of the Rydberg constant for hydrogen, and Catalan's remarkable paper on the spectrum of manganese, may be mentioned as two of many examples of work of this kind. It is a matter for regret that his new appointment entails the cessation of the very clear and interesting courses of lectures from which students of the Royal College of Science have benefited for more than twenty years, but there is no doubt that the gain to science resulting from his larger opportunities for research work will be immense.

Major Taylor has not occupied a professorial chair, but he is lecturer in mathematics at Trinity College, Cambridge, and will continue his work there as Prof. Fowler will at the Royal College of Science. The new professors may take part in instruction, or not, but no work of this kind is to be undertaken if it should prevent them from giving the best of their energies to research. The holders of the Yarrow research professorships are to devote their whole time to research in mathematical, physical, chemical, or engineering science. The professorships are similar to the Foulerton medical research professorship of 1400*l.* or more per annum, and may be compared with the Foulerton medical research studentship of 700*l.* per annum, the Sorby research fellowship of 600*l.* per annum, and the Beit memorial senior medical research fellowships of 600*l.* per annum. Particulars of these are given in the Yearbook of the Universities of the Empire (Appendix XXIV.). It may be of interest in connexion with these endowments to mention that there are a few similar foundations in the United States, notably the Heckscher Research Foundation, established in 1920 in Cornell University. "As research in America," said the founder, "suffers from the exhaustion of professors by teaching and other duties, it is my desire that professors and instructors . . . shall . . . for such periods of time as the university authorities may prescribe, be liberated partially or wholly from those duties," etc.; for the present the income is not to be used for permanent research professorships. Senator Vilas likewise bequeathed to the University of Wisconsin money for creating ten chairs of pure research without routine work, in which the salaries (10,000 dollars) would attract

men of worth. The experiences of Johns Hopkins and Clark Universities, both of which were intended to be institutions for original scientific research, have shown the great difficulties that stand in the way of establishing independently of the state a university which shall be exclusively a school of advanced studies.

In Canada, Queen's University of Kingston, Ontario, has a Chown science research chair (in physics or chemistry), which was recently vacated by Dr. A. L. Hughes on his acceptance of a chair of physics in the University of Washington, St. Louis; and in connexion with the University of Alberta two "research professors" have been employed under the direction of an Industrial Research Council, of which the Premier of the Province was chairman, their fields of investigation being fuels and road materials. In Australia, the University of Queensland has lately established a research professorship of medical psychology.

In deciding that for the present the income is not to be used for *permanent* research professorships, the Heckscher trustees may have been influenced by criticisms which have been directed against the Carnegie Institution of Washington on account of their heavy budget for permanent establishments, which seems not altogether consistent with the original idea of the founder—to discover exceptionally endowed men in various specialities and give them for the time being the broadest facilities for accomplishing more or less definite pieces of work. It is their immunity from the risk of becoming overweighted with fixed establishment charges that contributes so largely to the success of foundations like the Mellon Institute, where research is organised on a "job" or contract system, the problem being set by a person or firm interested in its solution, the scientific worker being found and engaged, *ad hoc*, by the Institute, and a "fellowship" being assigned for a definite period fixed with reference to the probable duration of the research; in many cases the fellow is promised a "bonus" (which has in some cases reached 10,000 dollars) or a percentage on the industrial exploitation of the process studied.

All these research foundations differ, however, from those now established by the Royal Society inasmuch as they are associated with particular institutions. In the Society's scheme, there is perfect freedom as to the place of research, and the main intention is to give an investigator of proved worth the means to continue his explorations of the field of Nature undisturbed by other duties, and with his eye always towards the light. We welcome the generous recognition thus given to research as a profession, and believe that the action described by Sir Charles Sherrington marks the beginning of an important epoch in the history of the Royal Society.

Electronic Theories for Chemists.

(1) *The Electron in Chemistry: being Five Lectures delivered at the Franklin Institute, Philadelphia.* By Sir J. J. Thomson. Pp. v+144. (Philadelphia: The Franklin Institute, 1923.) 1.75 dollars.

(2) *Valence, and the Structure of Atoms and Molecules.* By Prof. G. N. Lewis. (American Chemical Society Monograph Series.) Pp. 172. (New York: The Chemical Catalog Co., Inc., 1923.) 3 dollars.

(1) SIR JOSEPH THOMSON'S book contains the substance of five lectures which were delivered so recently as April of the present year. The reviewer believes that it was dedicated to chemists and has read it in that light, for in no other can he pretend to see.

As is well known, the author does not subscribe to all the newer physical doctrines and is hopeful of founding a theory of the atom with the aid of less revolutionary postulates. Starting from the conception of the atom as a massive, positively electrified centre surrounded by electrons, Sir Joseph Thomson begins by admitting that the properties of the atom require the introduction of some principle not recognised in the older physics. This principle he supposes to affect the law of force between the nucleus of the atom and the electrons in such a way that at a certain distance the force changes from attraction to repulsion. The introduction of a new term into the expression of the usual inverse square law gives the required result, albeit somewhat indifferently well, and the corresponding stability of various electrically neutral systems composed of electrons, apparently stationary, can be worked out. The now familiar octet emerges naturally enough from such considerations, but the origin of the pair of electrons which form the "shell" of the helium atom and the K layer of heavier elements is left obscure, nor is it at once evident why the octets of the inert gases are relatively so extremely stable.

If no more than an adumbration of the periodic system is to be seen in the somewhat tentative theory which the author here proposes, this fact should not be allowed to weigh too heavily against it, lest hereafter it may prove that other theories have sacrificed too much in order to retain a predetermined outward form.

In chapter ii. the combination of atoms by means of one, two, or more electrons is considered, and it is explained why lithium, beryllium, boron, and carbon are solids whilst oxygen, fluorine, and neon are gases, and why, for example, the study of the mode of scattering of polarised light by gases furnishes evidence that the molecule of oxygen is more elongated than that of, say, hydrogen. Careful readers, however, will note that nitrogen does not fit into the picture, and will

suspect that Sir Joseph Thomson has abandoned an earlier intention of assigning to the molecule of this element a configuration not unlike that of the atom of an inert gas.

The method of positive ray analysis, which originally we owe to the author's genius, has given many results which scarcely admit of misinterpretation, a virtue not always conspicuous in the conclusions derived from other methods of investigation of atoms and molecules. Chemists will therefore turn eagerly to those pages in which Sir Joseph Thomson explains how positive rays throw light upon the chemical properties of the elements.

Highly interesting and suggestive, too, are those sections of the work which treat of polar molecules and their importance in connexion with chemical reactivity, as, for example, the explosiveness of certain gas mixtures and the inertness of certain carefully dried systems such as those included in the classical experiments of H. B. Dixon and of H. B. Baker. These ideas on polarity are extended to explain electrolytic dissociation in solutions, the formation of the double layer, and the principle of the Armstrong hydroelectric machine, to mention only a few applications.

The conditions which give rise to the development of electrical polarity in a molecule are treated from an elementary point of view, and the principles are used to explain the varying acidness of hydroxylic compounds and substitution in hydrocarbons and their halogen derivatives.

Residual affinity, active molecules, Werner's co-ordination numbers, production of light during chemical change, magnetic characters of elements and compounds, and of oxygen in particular, are also considered. Nor does Sir Joseph Thomson omit discussion of Thiele's theory of conjugation and related questions; but the applications of his views to organic chemistry have undergone some modification since the book was written, as comparison with his recent contribution to the *Philosophical Magazine* will show.

The electronic theory of solids occupies the last chapter of the work, and as this involves the treatment of crystal structure, compressibilities of metals and other elements, surface tension, intermetallic compounds and mixed crystals, it will make a special appeal to chemists and metallurgists who can think in three dimensions, and there is much of interest for others.

The text is freely interspersed with mathematical symbols, but there is little that cannot be comprehended by those who have a knowledge of algebra and elementary physics. Chemists owe to Sir Joseph Thomson grateful thanks for a work which illuminates many of the dark corners of their science with the glow of his rich knowledge and experience.

(2) The current of orthodox opinion on electronic theories of valency has changed its course so often that the permanence of any one aspect of the subject cannot be assumed. Nevertheless, the adjective "ephemeral," which Prof. Lewis suggests in reference to his monograph as a whole, should properly be applied only to the latter half of the work. The earlier chapters, which deal with the pageant of discoveries and ideas which led up to the present position of our knowledge of the atom, could scarcely be bettered as an initiation to the subject, and are distinguished by an ingenious arrangement of the material and by the graphic way in which it is described.

Beginning with Dalton's conceptions of the discontinuity of matter, the author leads, by several converging paths in turn, to the ionic dissociation theory, to the discovery by J. J. Thomson of the electron, and to the electronic conception of the atom. The ideas of Abegg, Thomson, Kossel, and others in relation to the octet theory are explained, while an interesting reproduction of some of his own lecture notes of 1902 throws light on the embryology of the cubic atom.

Later in the book, Ramsay is credited with the first idea of electrons shared by two atoms (1908). Stark's conception of valency electrons attracting simultaneously the positive parts of two different atoms is given great prominence and illustrated with four diagrams. Parson and Kossel are not forgotten in this connexion, and the author generously makes out the best case for every possible claimant to a share in the development of the notion of co-valency.

The history of the Bohr atom is also expounded in the introductory chapters, and thus spectral series, radiant heat, specific heats at low temperatures, Planck's oscillators, the quantum theory, and Einstein's photoelectric equation come forward in turn for exposition, the significance of each being made clear. Bohr's theory of the hydrogen atom and some of its more striking applications to the theory of emission and X-ray spectra, ionisation and resonance potentials, are explained in a simple way.

Werner's theory of co-ordinated compounds, or at least that part of it now accepted as a permanently useful generalisation, might with advantage have been included in these earlier chapters, leaving its interpretation in terms of the electronic theories to be dealt with in the later and highly controversial sections of the work, where Prof. Lewis develops his own views with the aid of numerous applications both in organic and inorganic chemistry. Some of the electronic formulæ suggested are already well-known and provisionally accepted; others, including many which are novel, will be received with varying grades of satisfaction.

As was to be expected, the electron duplet is in this

book vested with an importance which eclipses that of the octet itself. The author dislikes odd numbers of electrons, and regards molecules such as that of the highly stable and colourless nitric oxide, with fifteen electrons, as obstructionists, like the single player and the three-ball match on the golf links. In this attitude he represents at present a considerable majority of physical chemists; but although this helps to keep speculation within bounds, there are nevertheless some who still feel that they derive advantage from practising in fields where these recalcitrant molecules appear as examples of reactive combinations and not as exceptions to any rule.

The author reconciles Bohr's theory with his own by assuming that the fixed position assigned by him to each electron in the atom represents the average position of the electron in its orbit. This interpretation, however, appears to the reviewer to be an arbitrary one which later on may prove untenable, and which necessarily brings into prominence the magnetic phenomena associated with the movement of the electron. However that may be, the device obviously clears the way for a classification of the elements based on Bohr's system, but always, in the hands of Prof. Lewis, with full acknowledgment to the sources of inspiration.

Where Sir Joseph Thomson relies mainly on forces of the electrostatic type, Prof. Lewis holds that "such forces are responsible neither for the fundamental arrangement of the electrons within the molecules nor for the bonds which hold the atoms together." In the present work, consequently, magnetic moments assume directive or causative functions corresponding with those attributed to electrical moments in the preceding work; it naturally follows that ionisation and numerous reactions which "verge on the ionic type" become not merely limiting cases, but, like molecules containing an odd number of electrons, definite exceptions to the system.

Considerable space is devoted to co-ordination, bivalent hydrogen, ionisation, and strengths of acids and bases. There is much here which is suggestive; but when, for example, Prof. Lewis (p. 107) quotes an opinion that "an aqueous solution of hydrochloric acid would have the properties of a weak acid if it were not for the formation of this hydronium chloride," he is not helpful, for this applies only to the conductivity of the solution and not to its "acidness."

A number of problems of special interest to the organic chemist are touched on, including conjugation, partial valencies, and tautomerism. Huggins's theory (1922) of the electronic structure of benzene, which closely resembles that suggested independently by R. Robinson, in a discussion at the Chemical Society early in the same year, is cautiously commended.

The last chapter, which deals very broadly with the discontinuity of physico-chemical processes, photochemical reactions, colour, and with the future of the quantum theory, displays the prepossessing features of the early sections of the work, which is eminently readable throughout.

The printers and publishers have ably supported the authors of these two works in producing attractive monographs. There appear to be very few errors or omissions. In Sir Joseph Thomson's book, on p. 41, line 26, for "electrons" read "atoms," and on p. 135, line 14 from the bottom, for "proposition" read "proportion"; in Prof. Lewis's book, two dots have inadvertently been omitted from the formula for butadiene on p. 91.

A. L.

Bruce of the *Scotia*.

A Naturalist at the Poles: the Life, Work, and Voyages of Dr. W. S. Bruce, the Polar Explorer. By Dr. R. N. Rudmose Brown. With Five Chapters by W. G. Burn Murdoch. Pp. 316 + 25 plates + 3 maps. (London: Seeley, Service and Co., Ltd., 1923.) 25*s*. net.

MR. RUDYARD KIPLING'S recent rectorial address on "Independence" gave general expression to the problem of those who in thought or action set themselves against the domination of "the Tribe," and here in the Life of Dr. W. S. Bruce we have an example of the career of one who did so. From this point of view, it might be wished that Dr. Rudmose Brown had been led to estimate in how far the "iron ration" on which Bruce relied was fitted to sustain him in his efforts to attain his ideals by his own exertions. Such a life, analysed with full knowledge of temperament, equipment, ambitions, and achievements, might bring enlightenment, help, and warning to others who are setting out on a scientific career. Yet the author was perhaps wiser not to make his biography a critical estimate of character. He has given an honest account of the work of a strenuous life in that spirit of sympathetic friendliness which Bruce inspired in all who knew him. From the facts set out in the narrative portion, read in the light of the two fine concluding chapters, "Ambitions and Dreams" and "The Man and his Work," the reader will not find it difficult to build up for himself an appreciation of the naturalist-explorer who differed in so many ways from the popular conception of a polar leader.

Bruce, when he first came to Edinburgh as a youth of seventeen, was a gentle, pathetic, lovable fellow full of vague visions and fine ideals, and no one suspected

that his shy, compliant nature was capable of holding on with the soft and flexible tenacity of a Chiton to any scheme on which his heart was set. Love of natural history was his dominant characteristic, and it drew him to the field and seashore rather than to the class-room. He completed no course of formal study and took no degree, remaining to the end an observer, collector, and organiser rather than a systematic or specialised man of science.

In a fascinating group of four introductory chapters and one of "Further Recollections," his old friend and companion, Mr. W. G. Burn Murdoch, reveals Bruce's early environment in Edinburgh, where he responded both to the magical stimulus of Prof. Patrick Geddes in science and to the emotional Celtic patriotism then pervading the University Hall where he lived. These chapters also describe the voyage on the *Balaena* to the Weddell Sea in 1892–3, when the spell of the polar regions fell on a mind which never after escaped its influence. After an account of the part Bruce played in the Jackson-Harmsworth Expedition to Franz Josef Land and in other private Arctic voyages, Dr. Rudmose Brown deals, with fuller knowledge than any one else possesses, with the origin, progress, and results of the Scottish National Antarctic Expedition to the Weddell Sea in 1902–4.

The solid results of the voyage of the *Scotia* entitle Bruce to a high place as an Antarctic explorer, though at the time he was rather overshadowed by the fame of the *Discovery*. The inception of the *Scotia* Expedition was his own, the funds for it were contributed by friends in response to his personal appeal; the plan of the cruise and the work done were original, dictated not by any external authority but by his own foresight and the chances which presented themselves in that region of unexpected obstacles and opportunities. How he looked on his assistants is shown by one of the too rare extracts from Bruce's diary on the *Scotia* (p. 148):

"I would like them to regard the ship as their university, as their *alma mater* in the highest possible sense, where they will be able to study the phenomena of Nature, without bias, from Nature itself; and learn that they, as well as their fellows, have many short-comings. I am here as leader rather than commander, in order to guide the work of others, so that the aggregate may be of the greatest possible value to science and the world."

Bruce's pertinacity secured the finest series of deep-sea soundings ever made in the far south, and numerous hauls of the dredge, trawl, and fish-traps in deeper Antarctic waters than any other expedition has investigated. The discovery of Coats Land was scarcely noticed by the public, for though it was a geographical result of the first order, Bruce's indifference to non-scientific opinion led him to make little of it in comparison with his oceanographical work, which interested the newspaper reader very little. The most permanent outcome of the *Scotia* Expedition is the meteorological station established on Laurie Island (61° S.), which, after being organised and kept up for a year by Mr. R. C. Mossman, was taken over and maintained by the Argentine Government.

Though his later years were to some extent clouded by a sense of grievance with the tardy and inadequate assistance rendered by his own Government, Bruce continued to carry on by himself work which would have taxed the resources of a well-endowed scientific institution, but he escaped at frequent intervals to solace himself in Spitsbergen solitudes. He created the Scottish Oceanographical Laboratory, he classified and distributed the abundant collections of the *Scotia*, and made considerable way with the publication of the scientific results of the expedition. Of his struggles in this effort Dr. Rudmose Brown says (p. 252):

"Bruce strained his own scanty means to breaking-point to keep the publications going. The proceeds of lectures, articles and sale of bird skins and eggs were all devoted to the same cause. He had a hard struggle to keep his laboratory open and meet the printing accounts, yet he insisted that all the results should be adequately dealt with and fully illustrated. The one contingency he resisted was the abandonment of his laboratory and his publications. Poverty he was ready to face and did face: only his most intimate friends at the time knew of his struggles. Through all those days he never lost hope. . . . But all his schemes were for the advancement of science; his own interests counted not at all."

Bruce had no expensive tastes or impulses, and only cared for money to enable him to carry on his work: to this his personal life was entirely subordinated. In the end he attained to recognition as the best authority in Great Britain on practical oceanography and polar natural history; all the more is it deplorable that his oceanographical laboratory was broken up in his lifetime, and the collections, in gathering which he had spent his life, dispersed, albeit within the bounds of his beloved Scotland.

Hugh Robert Mill.

Mendelian Inheritance and Eugenics.

Heredity and Eugenics. By Prof. R. Ruggles Gates. Pp. xiii + 288. (London: Constable and Co., Ltd., 1923.) 21*s*. net.

In the space of some 250 pages of well-produced matter, Prof. Gates has devoted himself to an examination of the known facts of human inheritance, with special reference to Mendelian inheritance. According to the preface, a compelling interest in

eugenics and a conviction that statesmen and law-makers alike have failed to realise how fully any intelligent attempt to improve the conditions and qualities of the human race must be founded on a knowledge of the manner in which qualities arise, are inherited, maintained or lost, have driven the author to glean from many sources. Thus he has been able to assemble in the present volume a crowded record of observations on the physical and mental characters of man, the results of the blending of races, the problems of population, and other aspects of eugenics, the main practice of which appears to be the production in the human frame of ready remedies for the evils of our social systems.

A general list of works bearing more or less directly on the infant subject of eugenics, and a bibliography of papers which have largely contributed to the matter of the text, complete the volume, and provide both ample reference for the general reader who would probe more deeply into recorded facts and opinions, and proof of the lively interest which has grown within the last two decades in Nature's laws which make or mar man's prospects from birth.

To maintain a well-born race is a natural aspiration involving no necessarily clear conception of the acme of human development of qualities either physical or mental; for although we cling to a vague ideal of a healthy mind in a healthy body and define more or less clearly the standards whereby we judge our fellow-creatures, there is no guarantee from the long pages of descent that the standards of human well-being for which we strive have kept in motion and in strength the main stream of human life.

It is well to realise how temporary are our aims, and that, in the practice of eugenics, our purposes are moulded more by our social systems than by a wide knowledge of whence man came and how, and of whither he is going and why, in the inexorable drifts of countless generations. To render better the span of life for our descendants is indeed a noble aim, the realisation of which must be based on a study of great tribal trends rather than on the application by one social cast to another of a knowledge of chromosomes, sex-linked inheritance, or the incidence of feeble-mindedness and colour-blindness. For man has come down the ages for good or ill by paths which neither a knowledge of inheritance nor a man-formed scheme of eugenics could have controlled effectively, and so he will go, despite our best endeavours, by the ceaseless drive of world-forces which eugenic practice can never mould to our will.

Much space is devoted in the text of the present volume to such topics as stature, eye-colour, hair-distribution, brachydactyly, and cataract, and to the occurrence of feeble-mindedness among the destitute, musical aptitude, and the limits within which characters of a parent persist in the offspring. But on the vital questions which are ever before us of the origin and meaning of any single character which declares itself in a life-span with a fate to be sealed in descent, there is silence. It is well that this should be fully realised, for it marks much of the current literature on eugenics, and stamps it as a speculation in futures of which we know nothing for lack of knowledge of the past. For Mendelian inheritance, on which eugenic practice so fully rests in its quest for the betterment of the human race, is little more than an elaborate distributing agency which deals in complex characters of unknown origin for which the future is obscure.

The book is well written and adequately illustrated: it will serve admirably as a guide to those who seek an honest statement of the present position of the principles on which the practice of eugenics is being built to-day.

J. McL. T.

Our Bookshelf.

Ultraviolet Radiation: its Properties, Production, Measurement, and Applications. By M. Luckiesh. Pp. xi+258+12 plates. (London: Crosby Lockwood and Son, 1923.) 21*s.* net.

WHEN Scheele in 1777 projected the visible spectrum upon silver chloride, he was on the verge of discovering ultraviolet radiation, but it escaped his attention. Ritter in 1801 noted the effect on silver chloride of what proved to be this new type of radiation. This was the starting-point of a series of discoveries of photo-chemical effects made in the early part of the nineteenth century. The limit of transparency of ordinary glass is in general at about 340 millimicrons. Quartz crystals were found to be transparent as far as 185 millimicrons. Instruments employing quartz made it possible to extend the ultraviolet spectrum greatly, and by using fluorite Schumann extended the explored region from 200 to 120 millimicrons. Lyman placed the light source in an exhausted spectrograph chamber, and by employing a reflection grating was able to extend the known spectrum to about 50 millimicrons. Recently, Millikan has spanned the gap between these short ultraviolet rays and X-rays.

A detailed account of the experimental work that has been done on the subject of ultraviolet radiation is provided in a recent work by Mr. M. Luckiesh of the Nela research laboratories. The author states that his aim is to present authentic data of such scope as to be useful to those who are interested in the subject. Theory has purposely been subordinated to experimental facts because the latter are not affected by the inevitable changes in theory. The result of his labours is to furnish a storehouse of information which will be of service to the chemist, the physicist, the engineer, the biologist, the ophthalmologist, and the physician, for to each this form of energy is of practical value.

After a short introduction and an account of the

ultraviolet light in solar radiation, the subject of transparency of gases, liquids, solids and, in particular, glasses, is discussed in detail. Then follow important chapters on the reflection and production of ultraviolet radiation, in which the many sources now available are described and compared. After describing the detection and measurement of the rays, the author discusses their effect upon living matter and various photochemical actions. Although the reader would have been grateful in some places for a more critical discussion, he must feel that he is indebted to the writer for the large number of investigations described and for the many references.

The Savile Club, 1868–1923. Pp. vii + 206. (Privately printed for the Committee of the Club, 1923.)

This book will not only be welcomed by members of the Savile Club generally, but will also be a source of interest and pleasure to all such "strangers" as may come to read the anonymous author's "round unvarnished tale" of the birth and growth of the club, which has well striven to retain the original characters impressed upon it by the principles laid down by its founders. The founders' desire was, in brief, to establish a club consisting of a "mixture of men of different professions and opinions" by "a careful process of election." The eminently readable and racy story of the Savile's progress that occupies seventy pages of this history, in conjunction with the interesting chronological list of members and committees given in the rest of the work, supplies good evidence that these principles have not been forgotten.

A careful study of the whole of this work, as regards both matter and manner, and especially the apt quotation in the preface from the *Spectator* (No. 34, April 9, 1711), suggest to the present writer a probable clue to its author's identity. Such an author must necessarily be a Savilian of very long standing, and intimately acquainted with many fellow-members. He must, further, have had the habit of going to the club very frequently, and be endowed with mighty memory for details. Added to all this, he must be a genuine devotee to the club's principles and traditions. It is not possible to find in the whole list of members any one but Sir Herbert Stephen who possesses this infinite variety of qualifications. This hypothesis concerning the authorship withstands the application of a crucial test—the spirit and style of this admirably composed record.

Readers of Nature may well take special interest in this book, which shows that the Savile Club has numbered among its younger members a large proportion of those who have become the most distinguished men of science in Great Britain and the world at large.

Electro-Chemistry related to Engineering. By W. R. Cooper. ("A Treatise of Electro-Chemistry," edited by Bertram Blount.) Pp. xiv + 136. (London, Bombay and Sydney: Constable and Co., Ltd., 1923.) 12*s.* 6*d.* net.

Every electrical engineer will admit that the science of electro-chemistry is of vital importance to his industry. All the copper he uses is refined exclusively by electro-deposition, and all the aluminium is produced electro-chemically. The electric refining of steel is now widely used, and so also is the electric production of ferro-alloys. These alloys have enabled wonderful results to be obtained in the construction of aircraft. Supply engineers have to be very careful not to let electricity leak from their mains, as the resulting "vagabond" currents corrode water- and gas-pipes. It is therefore advisable that they should know to what extent their stray currents produce this corrosion, and whether they will corrode reinforced concrete or not. We were particularly interested in the chapter on electrical precipitation of dust, smoke, and fume, and its commercial applications. Unfortunately the costs vary greatly with circumstances, so no general figures can be given; but we think that if the laws regulating the emission of smoke into the atmosphere were made a little more stringent, manufacturers would soon find it more economical to prevent it electrically. The chapter on electro-culture gives excellently and very briefly the present state of the art. Mr. Cooper's knowledge is acquired at first hand. In the final chapter he discusses the relative importance of cheap power and cheap freights. In some countries the cheap power available is more than counterbalanced by the high cost of transport. To scientific workers, and more especially to electricians, this book will prove useful.

In Witch-Bound Africa: an Account of the Primitive Kaonde Tribe and their Beliefs. By F. H. Melland. Pp. 316 + 24 plates. (London: Seeley, Service and Co., Ltd., 1923.) 21*s.* net.

While anthropologists frequently maintain the necessity for insight and sympathy in the administration of the affairs of backward races, it is not often that concrete examples of the peculiar psychology of primitive man are put to the layman so convincingly as some of the instances which Mr. Melland has singled out in this book. As an official of some twenty-two years' standing, he is in a position to speak with authority. From this point of view his book can be recommended heartily to every one interested in the government of our backward races.

On the scientific side, Mr. Melland's account of the Ba-Kaonde of Northern Rhodesia is equally important. The Ba-Kaonde consist of three elements, to which, however, the author gives a common name as a matter of convenience. He is of the opinion that they are offshoots of the Batuba. Some of their customs suggest an affinity with Central rather than South Africa. There is, for example, practically no "bride-price," but the husband stays with the bride's people for a period of from three to ten years, and his children belong to them. As the title of this book suggests, Mr. Melland is much impressed by the importance of witchcraft in the life of the people.

The Cultivation of Sugar Cane in Java: an Elementary Treatise on the Agriculture of the Sugar Cane in Java, and more especially on its Cultivation on the Krian Sugar Estate. By R. A. Quintus. Pp. xii + 164 + 38 plates. (London: Norman Rodger, 1923.) 12*s.* net.

The position occupied by Java as a cane-sugar producing country, and the care bestowed on the cultivation of the crop, ensures a welcome to a book in English dealing with the agricultural methods employed on an important estate in eastern Java. This volume,

written by the manager of the Krian estate, is virtually a text-book of sugar-planting under the conditions obtaining in Java. In addition to its utility as a practical guide, it should prove of interest from the point of view of comparative agriculture, since, in Java, local circumstances call for an intensive form of cultivation which does not obtain in all sugar-growing countries. The fundamental principles of sugar cultivation, however, are the same in all producing regions, and they are clearly set out by the author. There are two sections of the book. The first part, which is introductory, deals with cultural conditions in Java, and affords a discussion on soils, manuring, and the botany of the sugar-cane; while part two furnishes a practical account of the cultural methods adopted on the Krian estate, including operations down to the harvesting and transport of the cane, and deals also with certain aspects of estate administration. The book is excellently illustrated with photographs and coloured plates.

The Theory of Experimental Electricity. By W. C. Dampier Whetham. (Cambridge Physical Series.) Third edition. Pp. xi+349. (Cambridge: At the University Press, 1923.) 12*s.* 6*d.* net.

To students with a limited knowledge of mathematics who desire a sound theoretical basis on which to build we can heartily recommend this book. The author writes in a most interesting and convincing way, and gives an excellent preliminary introduction to the latest electrical theories, as well as a clear account of the apparatus and methods used in an electrical laboratory. He points out that according to the electron theory, matter is an electric manifestation, and so the mass of a body must be explicable as electric inertia. The electric inertia of a magnetic field can be represented as due to the motion of electric tubes of force in the luminiferous ether. In this way electric inertia is in its turn "explained" as "mechanical inertia" of the hypothetical substance invented to enable our minds to form a rational picture of other physical phenomena. The author points out that, in a certain sense, simplification is thus attained. All natural phenomena are referred to the properties of the ether. Nevertheless, the mystery is but changed. We may have explained matter in terms of ether, but how are we to explain ether? The book closes with this question unanswered.

Statistical Method. By Prof. Truman L. Kelley. (Text-book Series.) Pp. xi+390. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1923.) 18*s.* net.

This volume by an educationist should be of great service to those who use statistical methods in any field, since it provides a summary of nearly all, if not all, the methods which have been proposed for measuring relationship. This seems likely to be its chief use, but it includes also a discussion of frequency distributions and of Pearson's set of curves, with chapters on index-numbers and other special applications. The study begins with data already collected, but the introductory chapters outline the principles of tabulation and graphical representation. Although problems are suggested in several chapters, the book can scarcely be regarded as a text-book for beginners, being very condensed in many parts, with few worked examples, but rather is a critical survey. In the treatment of correlation much use is made of a symbol for $\sqrt{1-r^2}$ as "coefficient of alienation." Appendices supply a list of symbols used, a bibliography—which is not up-to-date as regards editions of books—and an extended table of deviates of the normal curve. The index is small but useful.

Eastern England: some Aspects of its Geography, with Special Reference to Economic Significance. By John Bygott. Pp. xv+358. (London: G. Routledge and Sons, Ltd., 1923.) 6*s.* net.

In this book the author has attempted with a large measure of success to make a geographical study of agricultural England, devoting his attention to East Anglia and Lincolnshire. The study is comprehensive and thoroughly geographical. In no aspect of the subject does Mr. Bygott lose touch with the effects of location, relief, soil, and climate, and he considers the region in the past as well as the present. The volume rises far above the rank of the ordinary text-book as a serious contribution to the regional geography of the British Isles. There is a little overlapping in places; occasionally condensation would not be amiss; and it might facilitate the use of the book if some of the statistical matter was arranged in tabular form; but these are all minor points, and do not materially detract from a useful volume. The numerous sketch-maps are not the strongest part of the book.

R. N. R. B.

The First Days of Man: as Narrated quite simply for Young Readers. By F. A. Kummer. (The Earth's Story, 1.) Pp. 293. (London: Hodder and Stoughton, Ltd., 1923.) 7*s.* 6*d.* net.

Although this little book does not call for extended notice, it is worth mention as a type of educational work which is more common in the United States than in Great Britain. After a preliminary chapter dealing with cosmic evolution, it gives the main outline of the development of civilisation up to the end of the Stone Age in a logical order and an attractive form suitable for quite young children. In the whole it keeps fairly closely to accepted fact and theory, while avoiding the more formal methods usually adopted in the elementary introductions to the results of archæological study which have hitherto been offered to the British public.

An Introduction to Mining Science: a Theoretical and Practical Textbook for Mining Students. By J. B. Coppock and G. A. Lodge. (Longmans' Technical Handicraft Series.) Second edition. Pp. xi+252. (London: Longmans, Green and Co., 1923.) 4*s.*

This book provides a sound and interesting course in elementary science, from the point of view of the needs of miners. It is clearly written, and is well printed and illustrated. The experiments are carefully described, although it is questionable whether a large class should prepare small specimens of nitroglycerine, and then pour them down the sinks, as directed (p. 186). In the experiment on p. 120, a bit of "compo" tubing is less likely to do damage than glass. The technical matters are well explained, and the book will be useful.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Polarisation of Double Bonds.

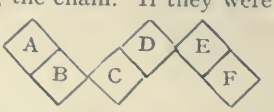
PROFS. LAPWORTH AND ROBINSON in a letter under the above title in NATURE of November 17, p. 722, raise some objections to a theory which I published in the *Philosophical Magazine* in September. The first of these objections is to the difference which I make between the action of an external electric field on singly- and doubly-bonded atoms. It seems to me that such a difference must exist. For, suppose that there is a double bond between two carbon atoms $C_2=C_1$, the octets of electrons round C_1 and C_2 have four electrons in common situated between C_1 and C_2. If an external electric field acts on the molecule, tending to make electrons move from left to right, some of the electrons held in common may be so far displaced from C_2 and towards C_1 that they can no longer be regarded as shared with C_2. If two of these are displaced far enough for this to happen, the octet round C_1 will be intact and C_1 will be saturated, while the octet round C_2 will be reduced to a sextet, so that C_2 will be unsaturated and chemically active; there are still two electrons left between C_1 and C_2 to form a single bond binding C_1 and C_2 together. If there were originally only a single bond between C_2-C_1, the octets round C_1 and C_2 have only two electrons in common; if one of these moves so far towards C_1 that it can no longer be regarded as completing the octet round C_2, so as to make this atom unsaturated and active, there will only be one electron left between C_1 and C_2 to bind them together. We should expect that they would easily come apart and form oppositely charged ions. Thus in this case neither of the carbon atoms would become active chemically while in combination.

Profs. Lapworth and Robinson object also that the effect of electrostatic induction would only be manifest at the beginning and end of a chain, that there would be no poles in intermediate positions. It is, however, only when the chain is entirely uniform that the evidences of polarity would be restricted to its ends. To take a very crude illustration: if we have a number of cubes of soft iron and place them face to face so as to form a uniform bar ABCDEF,

A	B	C	D	E	F

then if this were placed in a magnetic field where the force is parallel to the bar, the poles would be at or near the ends. If, however, they were arranged in diamond fashion,

there would be a series of consecutive poles at equal intervals along the chain. If they were arranged like



there would again be consecutive poles, but the intervals would be different. With regard to the objection that my theory involves Kekulé's structure for the benzene ring, I used this structure in my paper because it was the simplest and most definite. But unless all the carbon atoms in the ring are supposed to be the same in all respects, almost any theory would, I think, lead to analogous results.

Again, Profs. Lapworth and Robinson say that, according to the theory given in my paper, when vinyl chloride is acted upon by hydrochloric acid the result should be ClH_2C-CH_2Cl and not, as I say, $H_3C-CHCl_2$. I cannot agree with this at all. The effect of substituting Cl for H is on the theory to produce an electric field which attracts negative ions. This, it is true, will extend to the carbon atom in vinyl chloride which is not chlorinated, and make it more likely to attract a chlorine atom than it was before the chlorine was introduced. But when another Cl atom is introduced into the molecule the carbon atom to which it goes is determined not by the absolute value of the attraction in one part of the field but by the difference in the attraction. The Cl atom will go to the part of the field where the attraction is greatest, and this will be the part of the field nearest to the chlorine atom which is the origin of the attraction, so that the new chlorine atom will go to the carbon atom which is in this part of the field; that is, it will go to the carbon atom already chlorinated. J. J. THOMSON.

Trinity Lodge, Cambridge,
November 19.

Experiments on Ciona and Alytes.

IN NATURE of November 3, page 653, Mr. H. Munro Fox announces that he did not succeed in repeating my results in his Ciona experiments in Roscoff: amputated siphons regained only their normal length. Mr. Fox supposes that the extra growth in length of the siphons in my experiments was produced by extravagant feeding, and not by the regenerative activities of the animals.

Before Mr. Fox publishes the full account of his work, which he promises, I beg him to note the following facts, namely:

(1) The two principal cultures (operated and control) of my Ciona were placed at the same time and at the same stage of development, with the same provision of food, in two precisely similar aquaria, which stood beside each other. The dimensions of these aquaria were $300 \times 170 \times 100$ centimetres. I did not undertake a quantitative estimation of the number of micro-organisms present; but the food available was, so far as I could see, rather on the scanty than on the abundant side.

All the specimens in the control culture possessed short siphons, and therefore the influence of food on the length of siphon is excluded.

(2) I am not the first and only observer who has noted the "super-regeneration" of the siphons after they have been cut off several times. Mingazzini [1] asserts that siphons amputated three or four times at intervals of a month became longer after each regeneration. Mingazzini was able in this way to produce artificially the local variety, "macrosiphonica," found in the Gulf of Naples. I fully anticipated that the decisive experiment on regeneration and inheritance in Ciona would encounter violent contradiction. On that account I took care to construct this critical experiment out of experiments which had already been made by other investigators. That this was possible in the case of Ciona was one of the reasons which led me to choose this species. Indeed, I have had a predecessor (E. Schulz) also on the question of the regeneration of the "Keimplasma" out of somatic material, though his experiments were made not on Ciona but on another

[1] "Sulla regenerazione nei Tunicata," Bolletino Soc. Nat. Napoli, Series I., year 5, 1891. (An abstract of this paper appeared in the Naples *Zoologischer Jahresbericht* for 1891 under the head "Tunicata.")

Ascidian (Clavellina). The only originality which I claim is the combination of *well-known* experiments and their application to the solution of a problem of inheritance.

Barfurth,[2] after he had discovered (at that time in his laboratory at Dorpat) that the limbs of frog-larvæ had the power of regeneration, laid stress on the superiority of one positive result as against any number of negative results. "Even if only Dorpat tadpoles regenerated their limbs, nevertheless his result would be established." I make the same claim for Ciona, "even if only Ciona from Naples and Trieste grow long siphons." Finally, have perhaps only southern populations this power?

I make use of this opportunity to refer also to NATURE of September 14, in which Dr. W. Bateson writes again on the subject of Alytes. The type specimens of my experiments are in the Museum of Experimental Development attached to the Biological Institute of Vienna, and are the property of the Museum. I communicated Dr. Bateson's proposal to the directorate, and added, as my own opinion, that I was not in favour of exposing the critical specimen of Alytes with nuptial pads to the dangers of a second journey, only because Dr. Bateson had neglected the opportunity of examining it when he was able to do so. Nevertheless, I did not oppose a veto to the directorate sending the specimen if they wished to do so.

I was formerly very generous in lending type-specimens, but I have unfortunately had very unfavourable experiences in so doing. PAUL KAMMERER.

Vienna, November 10.

Problems of Hydrone and Water: the Origin of Electricity in Thunderstorms.

As one of my younger sons remarked to me some time ago—it is impossible, in these days, to get up a scrap! I challenge the current explanation—we cannot yet call it a *theory*, but, again, in these days, no one has care of words, every one calls his pet notion a theory—of the origin of the electricity let loose in thunderstorms, raising thereby an entirely fundamental issue. Yet no one dare face the problem. In these days, we have no regard for fundaments; our care is only for the chimney-pots; we devote ourselves to polishing these, forgetting that often the foundation of the house is yet to be built. I privately challenge the Sage of Salisbury, who formerly took some interest in electrical phenomena and lightning conductors and deigned to consort with us weak chemical vessels; his reply is proof that he has not seized my point and is "up above the world so high" that he cares only to contemplate electrons in transcendental garb, not in that of the vulgar raindrop. Big as he is, he has wrapped himself up snugly within the atom and won't consider what happens between at'ems—when they are molecules and interact.

I am sorry if I have depressed Dr. Simpson (NATURE, Oct. 27, p. 620). I well know that he bases his conclusions upon the experiments he has made. Unfortunately, from the sad experience of fifty years, I know that the results of experiments are often to be interpreted in opposite and equally plausible ways. Lenard and Dr. Simpson, so far as I am able to judge, have made experiments on very similar lines; the conclusions at which they arrive are different, however; rain, too, is sometimes negative, sometimes positive. I ask that exact stock may be taken of the work, and that we may know precisely what it is that has been measured. The feeling is upon me that the circuits dealt with were not so simple as is supposed.

We chemists are in grave difficulty. Physicists seem not only unwilling but also unable to grasp the spirit of our work; we are, therefore, forced to dabble in their field and naturally feel far from safe in dealing with electrical problems—though some of us have no hesitation in pronouncing on the electrical in'ards of the atom. If the physicists had sympathy with us, they would long since have tutored us and not allowed us to talk the nonsense we have indulged in, all these years, on the subject of ionic suicide in solution.

I am really posing a problem far deeper than that considered by Dr. Simpson. Whether energy be let loose in the division of big raindrops or when small ones unite matters relatively little to me—what I first want to know is whether, in such a liquid circuit, the energy would appear otherwise than as heat; whether, in fact, electrical energy can get loose from an electrodeless liquid circuit. This seems to me to be one of the fundamental problems to be solved in connexion with chemical change in solutions. The fire is a far more potent display of energy than a rain shower, yet we have no evidence of electricity being stormily loosed from it, however strong the draught up the chimney. I would beg for a Roland from Sir Oliver in this connexion: if he cannot meet me, I would ask some other Knight Physical to make his proclamation on the issue I have stated or, in some way, confound my inconvenient, if not improper, curiosity concerning an ordinary but always entrancing phenomenon. As to an external source, ultra-violet radiation must be doing something in the upper atmosphere. HENRY E. ARMSTRONG.

The Gorilla's Foot.

SINCE I have examined and sketched the feet of one or two dead gorillas in the Zoological Society's Gardens, may I be permitted to say that no one acquainted with the foot of this ape can dissent from Sir Ray Lankester's condemnation (NATURE, November 24, p. 758) of the photograph of the cast of the foot of the Kivu specimen published by Mr. Akeley? The photograph successfully conceals the fundamental resemblance, so far as mobility is concerned, between the hallux of the gorilla and that of monkeys, and suggests a resemblance, which does not exist, between the hallux of this ape and of man. It is, therefore, entirely misleading; but it is quite in keeping with Mr. Akeley's statement that the big toe in the gorilla "has grown away from the thumb, which is useful in climbing, towards the big toe, useful for walking" (*World's Work*, October 1922, p. 377).

Without any reflection being cast on Mr. Akeley's *bona fides*, that statement may be dismissed as incorrect, and as attesting the author's unfamiliarity with the structure of the gorilla's foot. Admittedly the hallux of the gorilla, like that of any monkey, can be stretched forwards so as to lie in contact with the adjoining edge of the next toe; but it cannot take up that position without forming a long and deep integumental crease on the sole of the foot. To the failure of Mr. Akeley's cast to reproduce this crease, showing the mobility of the hallux, must be mainly assigned the fictitiously human appearance of his photograph of the gorilla's foot. It is to be hoped that the duplicate cast will not be exhibited in the Natural History Museum without a label clearly explaining this misleading defect. R. I. POCOCK.

November 26.

NOTE.—While this letter was in the press, I saw at the Natural History Museum the duplicate cast above referred to. It shows quite clearly the deep crease mentioned; and the deceptive photograph would have revealed it, if proper attention had been paid to the direction of the light.

November 29.

Colour Vision and Colour Vision Theory.

In his letter on this subject which appeared in NATURE of September 29, p. 473, Dr. Edridge-Green apparently promised to deal with my explanations when these were given. In reply I selected two in which the full reasoning had been given, and I invited him to implement his undertaking. In his letter in NATURE of November 10, p. 687, he apparently declines to do so, and passes his burden on to the reader.

In none of his letters has Dr. Edridge-Green attempted to discuss my proofs, or indications of the proofs; but on the contrary he has in each letter merely made fresh assertions of other cases in which he presumes similarly that the trichromatic theory is incompetent. Nevertheless, ignoring the absence of discussion on his part, I took up each fresh assertion as it came, and dealt with it as with those which preceded. In his present letter he repeats the process, bringing forward three new cases. Since, in one of these, he deals with a statement of mine ("Colour Vision," p. 151), I shall, as before, discuss these new examples also, though that procedure cannot be continued indefinitely.

He seems to agree that my explanation of the absence of shortening of the spectrum at the red end after fatigue by yellow light is sound if the presumption made be true. But he asserts that the presumption is inconsistent with the work of König, Abney, and others. The presumption is that all three sensations are stimulated by visible light of any wave-length. Now Dr. Edridge-Green is wrong in asserting that this presumption is inconsistent with the *work* of König, Abney, and the others. It is certainly inconsistent with the *presumption* made alternatively by these investigators, which implied that the red sensation alone was stimulated by light near the red end of the spectrum. But the *work* never proved the correctness of that presumption, which, like the other, was quite a legitimate one nevertheless. For all conclusions regarding colour mixture, obtainable by one set of fundamentals, are necessarily obtainable by any other set linearly related thereto. The only type of work, by which discrimination between two otherwise suitable sets of fundamentals is possible, is work which deals with phenomena related to the sensations by a non-linear law. That condition was apparently unknown to Abney, and so he adopted the not necessarily true view that his selected fundamentals were absolute. They are certainly very convenient for observational work.

Dr. Edridge-Green then says that my explanation does not explain why there *is* shortening of the red end of the spectrum after fatigue by *red* light. Now that is an entirely separate point to which my explanation was not directed. But the trichromatic explanation thereof is quite simple and straightforward. The theory never asserts that lights of two different wave-lengths (yellow and red lights in the present case) will necessarily produce the same fatigue effects in any given region of the spectrum. The law of fatigue is not yet known, but the fatigue parameters used in the trichromatic theory are adequate fully to express it whenever they are formulated as functions of the various conditions which can affect fatigue. It is the absence of recognition of these and similar features of the moulding of the trichromatic theory which has led Dr. Edridge-Green into the erroneous statements unfortunately made by him so frequently regarding the powers of the theory.

Dr. Edridge-Green next raises another new point in saying that I do not "explain Shelford Bidwell's crucial experiment, namely, that his red borders are not seen with spectral yellow light but are seen with a mixed yellow made up of red and green matching it." Now Bidwell's experiment is in no sense crucial. The trichromatic theory has no *a priori* expectation that a pure yellow light and a mixed yellow light shall have the same effect with regard to border colours any more than it has with regard to fatigue. That is entirely dependent on the *nature* of the actions and interactions which are involved, a question on which the theory makes no fixed foregoing pronouncement. It is a matter for physical and physiological investigation. When that inquiry is settled, the theory will incorporate the result as an aid to the formulation of the parameters in terms of known quantities, just as in the case of fatigue discussed above. The theorist welcomes Bidwell's observations, and he is willing to give a similar welcome to those made by Dr. Edridge-Green.

The third and last new case is in the same position. Dr. Edridge-Green cites the gradual disappearance of the positive after-image of a spectrum, which proceeds successively from the red to the violet end. He says that the trichromatic theory states that the positive effect of the red sensation disappears before that of the green. The statement applies if we adopt (say) Abney's fundamentals, but might require modification otherwise. Yet that is not of any essential importance. But he proceeds to say that, "in an absolutely dark room, if pure spectral yellow light be thrown on a white screen and a flicker apparatus rotated slowly in front of it, the yellow will not change its hue; on the trichromatic theory it should become green. The results are quite different when stray light is allowed to fall on the screen as well." Now, while the trichromatic theorist will welcome any such verified data, he cannot admit any compulsion towards the expectation that the colour should become green. The conditions of the retinal illumination are entirely different in the two cases. So the results of the observations can only furnish information regarding the manner of variation of the decay parameters and of the threshold values as functions of the illumination and its duration and its quality, of the length of the rest interval, and also of the areal distribution of the illumination.

I am glad that Dr. Edridge-Green has brought forward these three examples, for they are typical of many cases in which the views of writers on the subject have been adversely affected by the stereotyping of ideas which, while being appropriate enough to the strong restrictions properly imposed in the earlier stages of the theoretical development, have long since been removed. W. PEDDIE.

Late Fertilisation and Sex-Ratio in Trout.

MRSIC[1] has shown that in rainbow trout late fertilisation—*i.e.* the retention of ova within the body of the female after they are fully ripe—results, as it does in frogs (Hertwig,[2] Kuschakewitsch[3]) in an increased percentage of males in the offspring. This is due (as also in frogs—Hertwig[4]) to the transformation into males of some of the young animals which had started to develop as females. The only difference between the frog and the trout is that, whereas in the former case the short period of 4 days' delay will cause *all* females to become transformed

[1] Mrsic, 1923, *Arch. Entw. Mech.*, 98. 129.
[2] Hertwig, R., 1912, *Biol. Centralbl.* 32.
[3] Kuschakewitsch, 1910, "Festschr. f. R. Hertwig," 1910.
[4] Hertwig, R., Sitz. Bayr. Ak. Wiss., 1921.

into males, in the trout a much longer period, in fact the utmost which the female parent will stand —21 days' delay—will only raise the proportion of males to about 67 per cent.

Working with the brown trout with shorter (4-14 days') periods of delay, I have obtained results of the same kind but not so marked.[5]

It was thought that it would be interesting to try the effects of delay outside the body. Accordingly, on December 13, 1922, all the ova of a large female brown trout were stripped into a basin. One portion (lot A) were fertilised immediately. The rest of the eggs were left in the basin, in the small amount of fluid which comes away with them, but without the addition of any water, although in a moist atmosphere. A second lot (B) was fertilised 2 days later, and a third and final lot (C) after a total delay of 4 days. The sperm of the same male was used for all three fertilisations.

The surviving young trout were preserved in October 1923. All which had died after hatching were also preserved, and all but 4 of these could be sexed.

The results may be tabulated as follows :

Lot.	Total ova fertilised.	Died before hatching.		Died after hatching.			Killed Oct. 1923.		Total sexed.		
		% of ova.	No.	% of hatched.	No.	% ♂.	No.	% ♂.	No.	% ♂.	P.E.
A	351	10·3	36	26·7	84	48·7	231	51·1	315	50·5	±1·90
B	286	55·2	158	64·1	82 (78 sexed)	48·7	46	47·8	124	48·4	±3·03
C	208	65·4	136	56·9	41	36·6	31	58·1	72	45·8	±3·52
Total	845	39·1	330	40·2	207 (203 sexed)	46·3	308	51·3	511	49·3	±1·49

None of the variation shown by these male percentages is statistically significant. For example, the difference between the ♂ percentages of A and B (totals sexed) is 2·1, with a P.E. of ±3·39 ; and that between those of A and C is 4·7±4·06. Even that between those for "C, died after hatching" and "C, killed Oct. 1923" is only 21·5±7·84, and must therefore be treated as an error of random sampling. Thus the treatment has *no effect* upon the sex-ratio.

The mortality rate, on the other hand, is markedly affected by the treatment. This is especially notable in the death-rate before hatching ; but even after hatching, although the controls show the abnormally large death-rate for the first ten months of 26·7 per cent. (due to an exceptionally bad attack of fungus-disease), that for the treated ova is more than twice as great. Mrsic (*loc. cit.*) found that over-ripeness within the body of the female exerted a deleterious effect upon the young fish, as had been previously shown for frogs by Witschi.[6] But in neither case was the mortality nearly so great as in these experiments. The increased mortality was thus merely something incidental to any abnormal treatment ; but the two treatments, of delay inside and delay outside the body, exert quite different effects in other respects upon the unfertilised ova.

The sex-ratio of adult (2- and 3-year old) trout, both brown and rainbow, reared in captivity is, I am informed by Mr. Stevens, Manager of the Midlands Fishery at Nailsworth, close to 66 per cent. ♂♂ in his experience. What brings about this marked increase in the number of males is not known (in all recorded experiments the sex-ratio of young fish 6-10 months old is close to 1 : 1). Differential elimination of females after attaining maturity would appear to be the only method by which it could come about, but the reason for this remains obscure.

I should like to take this opportunity of expressing my thanks to Mr. Stevens, without whose interest and help I could not have carried out the work. The expenses were defrayed out of a grant from the Royal Society.

JULIAN S. HUXLEY.

New College, Oxford.

P.S.—I have just heard from Mr. Rowland Hazard, the owner of one of the largest trout hatcheries in the United States, that the sex-ratio of adult fish in his experience varies considerably from year to year. This year it has been about 58 per cent. ♂♂ in 40,000 fish, but in most years the excess of males is less.

Is the Pentose of the Nucleotides formed under the Action of Insulin ?

We have read with interest the letter from Mr. C. Berkeley in NATURE of November 17, p. 724. Referring to the substance found in animal tissues after insulin, which gives the α-naphthol reaction, but is without reducing action on copper salts, he suggests that our failure to find reducing power after hydrolysis by acids may be due to a pentose constituent going over to furfural and being lost by volatilisation.

There are reasons which make it unlikely that this is the case. We find that on boiling a solution of the substance in the presence of 8 per cent. hydrochloric acid for three hours, there is no measurable change in the optical properties of the solution. This does not exclude the possibility of loss of pentose sugar owing to conversion to furfurol, since the optical properties of the residue may have been altered, with the result that no change would be observed. On the other hand, the substance gives little indication that it contains a pentose. The modification of the α-naphthol test in which strong hydrochloric acid is used in place of sulphuric would be likely to indicate the presence of pentoses, by a rapid appearance of a purple colour.

Using this test, a positive reaction is obtained only shortly after the sugar has been extracted from the tissue, and then only faintly. The substance is dried with difficulty at room temperature *in vacuo* over sulphuric acid. At the end of this period the α-naphthol reaction (using sulphuric acid) is given with diminished intensity, and in the course of weeks it may disappear entirely. The α-naphthol test is extremely sensitive, and since many proteins and their derivatives give a positive reaction, it is perhaps necessary to emphasise that the intensity of the colour given by the substance in question, as well as the method of extraction employed, point to the substance being of a true carbohydrate nature. Indications have been obtained that the substance is present in normal tissues.

Dudley and Marrian (*Biochem. Jour.* 17, p. 435, 1923) have shown that glycogen disappears almost entirely from the liver and muscles after insulin convulsions. The fact that the blood sugar of animals in convulsions may be restored to the normal level, and the animals be recovered, by injection of such substances as adrenalin or pituitrin, without injection of glucose, suggests that the carbohydrate reserves of the body have been converted into some form other than glycogen. That the Islets of Langerhans tissue contain unusually large amounts of pentose compounds is of great interest ; but this

fact need not lead to the conclusion that the function of insulin is to convert the sugar reserves of the body into pentose derivatives.

Fixation of Human Embryological and Cytological Material.

IT is known that it is very difficult to obtain well-preserved human material. Few medical men realise that five or ten minutes after the tissue has been removed, or after death, plasmolytic changes supervene, and in the fixed and stained sections the chromosomes have clumped badly, and the delicate lipoid cytoplasmic organellæ have become abnormal, or completely macerated. Recently, I have been studying certain human material, and find that nearly every type of histological preparation can be made from two fixing fluids as follows: one of the surgeon's assistants is given two bottles, one of Da Fano's cobalt nitrate formalin fluid, and one of Regaud's formalin-bichromate fluid. Pieces of tissue as large as the thumb may be thrown into these bottles, and afterwards cut into smaller pieces when they have been brought to the laboratory. It is better to change into new fluid at once, especially if the organ is very vascular, and the fixing fluid mixed with blood.

For human material I find that fixation overnight in the Da Fano fluid gives the best results. Next morning some of the pieces are taken through as usual for Da Fano's method ("Microtomists' Vade-mecum," p. 437), but other pieces are washed in distilled water for ten or fifteen minutes and transferred some to 2 per cent. OsO_4, others to Champy's fluid (chromeosmium). The OsO_4 pieces are used for the Sjövall method (*ibid.* p. 331). From this batch of material, originally fixed in Da Fano, one gets sections which generally show the inner Golgi apparatus (Da Fano and Sjövall), the mitochondria (chromeosmium and sometimes Sjövall), neutral fat and lipoids (chromeosmium), and general nuclear structures and mitochondria (Da Fano fixation, staining in iron hæmatoxylin).

The other batch of material, fixed in Regaud's formol-bichromate, is partly carried through for the Regaud-Bensley-Cowdry method (*ibid.* p. 324), but other pieces of tissue are taken through Schridde (*ibid.* p. 325). These methods give the mitochondria (Regaud), mitochondria and fat (Schridde), and such sections stain nicely in safranin—light green, and in Mann's methyl blue eosin. For secretion and excretion granules, zymogen, yolk, fat, Golgi apparatus, and mitochondria, these two batches of material will give complete results.

For chromosomes, a batch of material in some Bouin formula (*ibid.* p. 306) is recommended.

Linnean Nomenclature.

IN the admirable review of Dr. Daydon Jackson's "Linnæus" (NATURE, November 17) there is one paragraph (last on p. 715) from which I am not sure that I extract all the meaning. This may be because I am a systematic zoologist and not a botanist; but I did begin my work on those lines with the study of Linné's "Philosophia botanica." That book taught me that the *nomen triviale* was no entity, merely a part of the *nomen specificum*, which consists of the *nomen genericum* qualified by the *nomen triviale*. Thus, "man" being the genus, "a good man" is the species; but "good" cannot stand apart from "man," for it is relative to "man" alone. Now take your good man and make him an admiral; he may be a bad admiral. Is that what the reviewer means? Does he imply that, if a species be rightly transferred to another genus, the *nomen triviale* is open to change? If this be his meaning, then it seems to ignore the distinction between a mere name and an epithet. When Jane Smith marries John Brown, she becomes (by custom) Jane Brown. She may thereby even change her nationality, but she remains Jane, and that is how we identify her, although "Jane" by itself is meaningless.

What then, some of us are asking, are the "philosophical positions" from which we have retreated; what are the "sound scientific principles" we have abandoned?

F. A. BATHER.

I REGRET to learn that one of my remarks has proved obscure to zoologists. A note by Linnæus that *nomen specificum sine generico est quasi pistillum sine campana* is accompanied by a cross reference to the denominational canon *nomen specificum sine generico est quasi campana sine pistillo*. The generalisation of the exemplar lends emphasis to the axiom embedded in the canon. That axiom was almost universally accepted by botanists in Great Britain until 1905, when representatives of their science, in international congress assembled, decided by a majority vote that the two portions of a *nomen specificum* may receive differential treatment. I am satisfied that, in reaching this conclusion, the botanists who constituted the majority when that vote was taken abandoned sound scientific principles and retreated from a philosophical position secured by Linnæus for botany. It may be that zoologists regard as justifiable the botanical practice which ignores the axiom accepted here until 1905; if so, there is no more to be said. But, that further misunderstanding be avoided, I may explain that I accept the principle of government by majority: whatever be the merit in civic life of conscientious objection and passive resistance, I regard both as unsuitable methods in descriptive science. This does not deprive me of the right, when dealing with the teaching of Linnæus, to express my conviction that the practical application of a particular Linnean canon which prevailed before 1905 was sound, and that the alternative practice, which obtains in botany to-day, is less satisfactory. I may add that I have not had in mind any of the methods in use in the denomination of individuals, but the teaching of an English naturalist, contemporary with Linnæus, in respect of analogous reasoning.

THE REVIEWER.

Bessemer Steel.

IN a review in the issue of NATURE of November 17, p. 716, of the second volume of Roscoe and Schorlemmer's "Treatise on Chemistry," the following sentences occur:—"The revisers have been perhaps a little too careful in retaining old matter in the text. The full details which are still given of the Leblanc soda process and of the Bessemer process for steel are really of historical interest only now that the last Leblanc plant and Bessemer converter have been shut down."

I have consulted the Statistical Bulletin of the National Federation of Iron and Steel Manufacturers, which gives the official figures of steel production in Great Britain at the present time, and I find that in

September 1923, 37,000 tons were manufactured by the acid, and 9000 tons by the basic Bessemer process. Very large quantities of basic Bessemer steel are being made in Germany and Belgium at the present time.

So far, therefore, as the above quotation relates to the Bessemer process, it is entirely inaccurate and the revisers are quite justified in giving details. The funeral of the Bessemer process has frequently been predicted, but it has never taken place.

H. C. H. CARPENTER.

Royal School of Mines,
South Kensington, London, S.W.7,
November 19.

PROF. CARPENTER is evidently right, and I am glad that he has corrected my mistake in reference to the Bessemer converter,—the statement as to the Leblanc process was, I believe, correct. It would be of interest, however, if Prof. Carpenter could give the date of construction of the last new Bessemer plant erected in Great Britain for steel manufacture. If new plants are not being constructed, the view that the Bessemer process for steel is really "of historical interest only," would not be altogether unjustified, since this process would then rank, like the hansom cab, as one of the products of the Victorian age, of which the usefulness is likely to diminish rather than to increase in the twentieth century.

THE REVIEWER.

The Spectra of Fifth Group Metals.

WE have photographed the absorption spectrum of bismuth and also the spectrum of the thermionic discharge at potentials ranging between 4 and 60 volts. Several stages in the excitation of the arc spectrum, and at least two classes of spark lines, have been recognised; 64 arc lines have been classified. The spectrum of the neutral atom is characterised by wide doublets, and most of the energy-levels so far identified are of p-type.

Electrical measurements of the arcing potential and potentials of inelastic impact were made by two of the authors and the late Dr. Oswald Rognley in 1918. They found inelastic collisions at intervals of $2\cdot0 \pm 0\cdot2$ volts and ionisation at $8\cdot0 \pm 0\cdot5$ volts. The interpretation is as follows:

The first resonance potential, 2·0 volts, represents the mean of the excitation voltages for several weak spectral lines of the type $mp - np'$. At 4·0 volts, we obtain the strong *raies ultimes*, λλ 3067 and 4722 Å.U. Excitation stages above 5 volts are difficult to separate. The first spark spectrum appears near 14 volts.

The absorption spectrum at 800°–1000° C. shows lines due to the atom, and prominent bands which have not been described previously. A group of seventeen bands lies between 2874 and 2672 Å.U., while a second group extends from 2205 Å.U. toward shorter wave lengths. At lower temperatures the bands disappear though the lines still may be recognised. They lie at 3067, 2276, 2230, 2228, and 1954 Å.U., and all originate on the lowest energy-level of the atom. No absorption lines arising from other levels were observed, even at a temperature of 1050° C.

Practically all the arc lines of arsenic between 3119 and 2000 Å.U. can be classified by means of constant differences found by Kayser and Runge (*Ann. d. Physik*, v. 52, 1894). We have discovered a few additional classifications. This spectrum is remarkable in that it possesses no lines in the visible region. There is a range of 38,000 cm.$^{-1}$ and another of 32,000 cm.$^{-1}$ in which no energy levels have been found. If there are energy levels in these regions, they can probably be detected only by the discovery of new lines, or the utilisation of lines at present listed in the spark spectrum. The potential of inelastic impact, 4·7 volts, given by Foote, Rognley, and Mohler (*Phys. Rev.*, 13, 59, 1919) corresponds to the mean of the wave numbers of the *raies ultimes*. The classification of the spectrum shows that the ionisation potential must be at least 10·6 volts, while the experimental value is 11·5 volts.

Mesozoic Insects of Queensland.

LEST the reference in NATURE of July 7, p. 20, to Queensland Geological Survey Publication, No. 273, may lead readers to think that the account of the Coleoptera is the first published work on the insects from the six-inch seam containing insect remains at Ipswich, I would point out that a series of papers dealing with these insects has already been published by Dr. R. J. Tillyard (Queensland Geol. Survey, Pub. 253, 1916; and "Mesozoic Insects of Queensland," Nos. 1 to 9, Proc. Linn. Soc. N.S.W., 1917 to 1922).

A. B. WALKOM,
Secretary.

Linnean Society of New South Wales,
Sydney, October 2.

[The paragraph to which Dr. Walkom refers was intended to direct attention to a particular piece of work, and no attempt was made to mention earlier publications on the same subject, though the contributor was familiar with them.—EDITOR, NATURE.]

Hafnium or Jargonium.

THE recent discovery of hafnium in minerals containing zirconium serves to remind us of the discovery of jargonium by Sorby in 1869 (*Chem. News*, vol. 20). He found that many zircons contained as much as 10 per cent. of the new element. The two closely-related elements, zirconium and jargonium, could be most readily distinguished by spectroscopic methods. Sorby and Forbes found that there was such a marked difference in the solubilities of the chlorides in strong hydrochloric acid, that it was possible to make a qualitative separation. Three years later Cochran investigated this subject and suggested that zirconia and jargonia were identical. My object in bringing this matter before readers of NATURE is to suggest that the work of Sorby may possibly entitle him to rank as the discoverer of the new element of atomic number 72, and that jargonium may have priority over hafnium and celtium.

Solid Solutions and Inter-Metallic Compounds.

By Dr. WALTER ROSENHAIN, F.R.S.

METALLURGICAL research during the past twenty years has been largely devoted to the study of alloys, and as one result we now possess a series of more or less complicated equilibrium diagrams representing the constitution of most of the binary and of some of the ternary systems. While, on one hand, increasing accuracy of methods has rendered these diagrams far more complex than was at first supposed, a careful examination of those which are most thoroughly established suggests that, widely as they vary among themselves, there are certain regularities which point to some common fundamental principle which, if once grasped, would exhibit these varied diagrams as parts of an intelligible whole. Fortunately, at the time when this great mass of disconnected knowledge lies awaiting synthetic treatment, the results of X-ray analysis applied to the study of the inner structure of crystals have become available. As the result of an endeavour to apply these results to the explanation of the behaviour of alloys systems, the writer has arrived at a theory which, on a simple basis, promises to afford an easy explanation of many, if not of all, of the properties of alloys, and to afford a much deeper insight into the nature of solid solutions and of inter-metallic compounds, and through them to throw new light on the nature of inter-atomic relationships.

The theory in question has been fully stated in two recent papers, and need only be briefly summarised here.[1] A metallic solid solution is an aggregate of crystals which, when in equilibrium, are homogeneous in composition, so that both the solvent metal and the solute metal are present in the same proportions in all the crystals. The present theory of the constitution of such crystals is based on three fundamental principles, the first of which has now received considerable experimental verification, while the other two appear to follow almost unavoidably. The first is that a solid-solution crystal is built up of the two kinds of atoms, those of the solvent and of the solute, upon a single space-lattice which is, substantially, that of the solvent, so that the atoms of the solute may be regarded as being simply substituted for an equal number of atoms of the solvent on the "parent" lattice. Measurements of the lattice-constants of certain groups of solid-solution alloys and comparison of the results with the measured densities of the alloys have strongly confirmed this view. The evidence already obtained indicates that this is the inner structure of practically all inter-metallic solid solutions, but some room for doubt may still exist in regard to certain metalloids, such as carbon or phosphorus.

Next, in a crystal built up in this manner of two kinds of atoms upon a single, simple space-lattice, the inference can scarcely be avoided that a certain degree of distortion of the lattice must result. The nature of this distortion must depend upon the character of the two kinds of atoms concerned; there may be either expansion or contraction of the parent lattice, and this may be either mainly local or mainly general. The degree and nature of this distortion will depend upon the extent to which the solute atom differs from the solvent, and also upon the general character of the solvent lattice, but these are details which need not be considered here. We may pass on to the third fundamental conception—that the extent to which any given space-lattice can be distorted, and particularly expanded, is strictly limited—that there is, in fact, for each pair of atoms a limiting distance beyond which the bond between them—whatever its nature—ceases to act. This rule of a limiting maximum lattice constant or parameter leads to a series of interesting inferences. Thus, a uniform undistorted lattice of a pure substance will be uniformly expanded by heat until the limiting parameter is attained; at this point the atoms throughout the lattice will lose their power of cohesion and the crystal melts. In a solid solution crystal, the lattice may be locally expanded by the presence of solute atoms; under thermal expansion those expanded regions of the lattice will reach the limiting parameter at a temperature where the less expanded portions of the lattice are still well below the limiting value; the result will be commencement of fusion in those regions of the crystals richest in solute and the formation of a liquid richer in solute than the remaining solid. This consideration explains why, in solid solutions, we generally find a melting range instead of a single melting point. Where the solute atoms cause expansion of the lattice the melting temperatures will be depressed by successive additions of solute. On the other hand, where the presence of the solute atoms causes a contraction of the solvent lattice, there will be a rise of melting point and the first liquid to be formed on fusion is richer in solute than the residual solid. These latter inferences have been strikingly verified in such cases as those of solid solutions formed by the addition of palladium to silver or of nickel to copper.

A considerable number of further inferences can be drawn from the three fundamental principles of the present theory of the inner structure of solid solutions—for example, the striking inverse relationship which is found to hold between the solubility of one metal in another and its hardening effect upon it, and the relationship between the hardness, high melting point, and high elastic modulus of a metal on one side and its power of forming solid solutions on the other. The theory has even made it possible to suggest an explanation of the properties of metals and alloys in regard to electrical conductivity. Whatever the true mechanism of electric conduction, there can be no doubt that it is associated with the movement of electrons through the metal; it is now suggested that where the atoms lie on perfectly straight lines on the space-lattice the movement of electrons is entirely unhindered and the metal in that state should exhibit super-conductivity. This can only be fully realised very near the absolute zero, since at higher tempera-

[1] "Solid Solutions," Second Annual Lecture of the Inst. of Metals Division, American Inst. Mining Engineers, New York, Feb. 1923; and "The Inner Structure of Alloys," Thirteenth May Lecture to the Inst. of Metals, London, May, 1923. Journ. Inst. Metals, 1923, ii.

tures the thermal agitation of the atoms disturbs their perfect alignment even in a pure metal. Since it is sufficient for one line or at most a few lines of atoms to be perfectly straight at any given instance—since such a single line would conduct infinitely well—super-conductivity must set in at a temperature slightly above and not only at actual absolute zero. In a solid solution crystal, however, the atoms can never attain perfect alignment, owing to the lattice-distortion, and consequently the electrical conductivity of a solid solution will always be relatively very low, and even at absolute zero, real super-conductivity cannot occur. Further, since the solid-solution lattice is considerably distorted to begin with, the disturbing effect of thermal agitation will be relatively much less than in a pure metal; in certain circumstances, indeed, thermal expansion may partially relieve the distortion —in those cases, in fact, where solid solubility increases with rising temperature. Consequently, in solid solution alloys the temperature coefficient of electrical conductivity will be much lower than in pure metals, while in some special cases it may even become negative. The theory, as comparison of these inferences with well-known facts at once indicates, offers at all events a good qualitative explanation, and at a later stage even quantitative prediction of electrical properties should be possible. The difficulty here, and indeed throughout the theory, in arriving at numerical results lies in the fact that while the average distorting—*i.e.* expanding or contracting effect of dissolved atoms on a lattice—can be measured with considerable ease and accuracy by the aid of X-ray spectrometry, the maximum local distortion cannot as yet be determined directly. When this difficulty has been overcome, considerable further progress should become possible.

We may now briefly consider inter-metallic compounds. These are known to metallurgists from the occurrence of certain kinds of singular points on equilibrium diagrams and from characteristic features of micro-structure and of physical properties, but there are a number of alloys in which the existence of definite compounds has hitherto been regarded as doubtful. Again, the results of X-ray analysis, combined with the indications of the above theory, prove helpful. Very typical of inter-metallic compounds is the body $CuAl_2$ found in copper-aluminium alloys. It is a hard, brittle body, tending to crystallise in well-formed long needles. Its atomic structure has been determined by Dr. Owen and Mr. Preston at the National Physical Laboratory. The lattice-structure is shown in the accompanying diagram (Fig. 1). The most striking feature is that certain pairs of aluminium atoms approach one another within a range, centre to centre, of only 2·42 Ångström units. In an aluminium crystal the lattice-constant is 4·85 Å and the closest approach is 2·86 Å, and it would be quite impossible, by the application of external pressure, for example, to force the atoms so closely together as they are placed in the compound. The inference, which is justified by comparison with the known lattice structures of other chemical compounds, is that the very much closer approach of atoms in this manner is a characteristic, if not *the* characteristic, feature of chemical combination as distinct from the "cohesion bonding" which occurs in the building up of a crystal. It would seem, in the present case, that the copper atom which is combined with the two aluminium atoms has taken away or absorbed something from the aluminium atoms which now allows them to come much closer together. This may well be the absorption of certain exterior electrons by the copper atom; whatever the detailed mechanism may be, it is probably the essence of chemical combination, and furnishes us at once with a definite criterion for distinguishing between solid solutions and compounds. At first sight one might perhaps expect that intermediate classes of structure should be found, in which the inter-atomic distances might be only slightly less than in the typical solid solutions. If our current views of the structure of the atom in "shells" or layers of electrons is correct, however, this should not be the case; we should find either substances in which there is nothing more than "cohesion bonding" without closer approach of the atoms, or bodies in which the atoms are drawn closer by a definite step.

There is a further distinction which can be inferred from the present theory. In a body of the solid solution type, atoms of one kind are readily replaceable by atoms of the other; in a compound, on the other hand, it would be difficult to conceive of any atom being replaced by an atom of the other constituent. In the $CuAl_2$ structure, for example, it is scarcely possible that any of the aluminium atoms could be replaced by a copper atom. This very definite inference is verified by reference to the equilibrium diagrams of alloy systems in which typical well-defined compounds are to be found—these bodies never exhibit any appreciable amount of dissolving power for their constituents. If we may extend this view to those cases which, metallurgically, are still regarded as doubtful, it will at once serve to classify them into compounds and solid solutions respectively. A well-known group of alloys of this kind is the copper-zinc alloys (brasses), which exhibit a series of solid solutions generally called the alpha, beta, and gamma phases. These are micrographically distinct, and vary widely in many of their properties, and it has been thought that each was based upon a definite chemical compound possessing a wide range of dissolving power for copper and zinc.

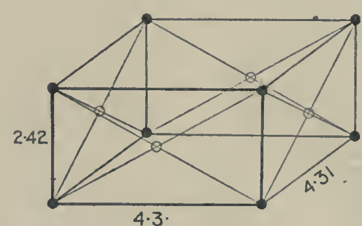

Fig. 1.—Lattice structure of $CuAl_2$.
● Cu. ○ Al.

In one of the papers mentioned above (May lecture) the writer suggested that these bodies need not be, and probably were not, based on definite compounds, but that they would probably be found to be based upon what might be termed allotrope lattices of copper. In the case of iron and nickel, for example, it is known

that the presence of a sufficient proportion of nickel will maintain the iron in the face-centred cubic lattice of the gamma phase at a temperature at which, in the absence of nickel, the iron would have reverted to the body-centred cube of the alpha phase. Presumably the iron remains in the gamma condition because in that condition it can retain a larger proportion of nickel atoms on the lattice, and because this arrangement involves less potential energy than any alternative. In the same way it was thought that the usual face-centred cubic lattice of copper might, when in the presence of more zinc atoms than can be carried on that lattice without undue distortion, be transformed into another lattice—still essentially a lattice of copper—but capable of carrying a larger number of zinc atoms, and that at a still higher concentration of zinc a further modification of the lattice might occur. Each successive modification would, in such a case, be expected to show an increasing approximation to the hexagonal lattice of zinc itself. Actual determinations of the lattices of the beta and gamma phases of the copper-zinc system, made by Owen and Preston in consequence of this suggestion, have completely verified it. The two phases show no compound lattice, but a modified copper lattice.

Another point of some interest in the distinction between solid solutions and compounds may be briefly considered. A good deal of consideration has been given by Tammann [2] to the chemical properties of solid solutions, Tammann's work being based on the idea of a substitution structure, but without reference to lattice distortion. If this principle is applied, however, an interesting conclusion may be drawn, to which attention was first directed by Mr. Preston, in regard to what may be termed "symmetrical" solid solutions. In any alloy system forming a continuous series of solid solutions between two metals, alloys must occur in which the two kinds of atoms are present in some simple ratio such as one to one, two to one, three to one, etc. According to the particular nature of the lattice system in each case, some of these simple ratios will allow the atoms to arrange themselves in a perfectly symmetrical manner. Such perfectly symmetrical atomic arrangement, however, is not likely to be attained or approached except in specially favourable circumstances. Very gradual cooling from fusion and a considerable rate of diffusion are essentials, but there is the further condition that the symmetrical arrangement in question should be a simple one. Thus in any lattice, an arrangement in which alternate layers or planes of atoms consist each exclusively of one kind of atom would seem to be such a simple arrangement. In the face-centred cubic lattice a one-to-one ratio allows of such an arrangement, all the atoms at the cube corners and those at the centres of two opposite faces being occupied by one kind of atom and the remaining four face-centres by the second kind of atom. In such a lattice, another simple symmetrical arrangement, but one less easily formed by the process of diffusion required by the present theory, is that in which all the face-centres are occupied by one kind of atom and all the cube corners by the other, this implying an atomic ratio of three to one.

The special interest which attaches to such perfectly symmetrical arrangements is that, if fully attained, there will be in such a lattice a perfectly uniform atomic spacing. The consequence must be, if the present theory is correct, a single melting-point and relatively low hardness and electrical resistivity. In some alloy systems, this state of affairs is so closely approached that it becomes plainly visible on the equilibrium diagram as experimentally determined, and the presence of a compound at the simple atomic ratio in question has sometimes been inferred—wrongly, according to the present view. In other systems, where diffusion is slow and uniform geometrical arrangement, therefore, is practically unattainable, the ideal condition is never reached experimentally, but the "solidus" curve shows an inflexion towards the "liquidus" in the neighbourhood of the "symmetrical" composition—in several examples near the one-to-one ratio of atomic concentration. In some alloy systems two such inflexions, corresponding approximately to two such ratios, have been observed. Although these inflexions have become increasingly definite in the best-determined diagrams, so that they could not be ascribed to experimental error, no explanation has as yet been offered. The fact that these details are only to be seen clearly in recent diagrams, prepared by methods of extremely slow cooling of the alloys, tallies well with the requirements of our theory.

Inferences from the substitution and lattice-distortion theory could be pursued at much greater length; so far, no failure of such an inference, when tested by means either of older well-established fact or by special experiments, has yet been found. There is thus some hope that a small but real step has been taken towards the better understanding of the nature of alloys, and particularly of solid solutions and intermetallic compounds.

Weather Influences in the British Isles.

By C. E. P. Brooks.

THE sun is the only source of terrestrial weather in the sense that the difference between the amount of solar radiation received in different latitudes is the driving force of the atmospheric circulation. The complexity of the earth's surface combined with its rotation about an axis introduces corresponding complexities into this circulation, but H. H. Clayton considers that "if there were no variation in solar radiation the atmospheric motions would establish a stable system with exchanges of air between equator and pole and between ocean and land, in which the only variations would be daily and annual changes set in operation by the relative motions of earth and sun; the existing changes we call weather have their origin chiefly, if not entirely, in the variation of solar radiation." It has been found that some parts of the

earth, especially the tropics, respond readily to these solar variations, while in other parts the solar variation is almost completely masked by secondary modifications. Hence we may classify weather influences into two classes: solar, in which the influence of solar variation is directly recognisable, and terrestrial, depending on causes which at first sight are entirely due to the influence of the land, sea, or atmosphere. These two classes shade into each other, with no definite line between them.

The weather of the British Isles, apart from seasonal temperature changes, is almost entirely terrestrial in its control, being dependent on the distribution of pressure over the North Atlantic and Arctic Oceans and the continent of Europe. This distribution is constantly changing, and we experience a succession of "depressions" and "highs" which pass across or near these islands, bringing our notoriously variable weather. Careful examination of a series of daily weather charts shows, however, that the most rapid changes are generally only in details, the main features of the pressure distribution changing comparatively slowly, and four main types of weather have long been recognised. These are named after the cardinal points whence blow the winds characteristic of the type—southerly, westerly, northerly, and easterly.

In the southerly type, pressure is high over Europe and low over the North Atlantic. Depressions are continually appearing over the ocean, but their centres fail to reach the British Isles, so that we are situated between a depression to the west and an anticyclone to the east, a condition which brings southerly winds and warm weather. The amount of rainfall depends on whether the high or the low pressure predominates over the British Isles; it decreases from west to east. In the westerly type, pressure is high in the south and low in the north, and depressions appear from the Atlantic and pass rapidly eastward, generally along a track somewhat to the north of Scotland. This type brings fresh westerly winds; spells of a day or two of very fine weather alternate with spells with more or less rain, the actual amount being least when the storm tracks lie farthest north. If in addition to high pressure to the south an anticyclone develops over Iceland, with a trough of low pressure between, the depressions pass directly across the British Isles and very rainy weather is experienced, sometimes with destructive gales. On the other hand, when the southern anticyclone extends so far north as to include Great Britain, very fine weather is experienced, which, if prolonged, as in 1921, may give rise to a serious drought. A moderate development of the westerly type forms about seventy per cent. of our weather.

The northerly and easterly types are more or less reversals of the southerly and westerly types; the easterly type proverbially brings us our most unpleasant weather. These weather types may persist for periods varying from a few days to weeks, and unfortunately there is generally little means of knowing, when a type first becomes established, how long it is likely to continue. Some cases are more favourable, notably the formation of a large anticyclone centred directly over the British Isles. In such a case a long spell of fair weather is very probable, and when this distribution was established on September 26, 1921, a long-range forecast of fair weather for the next fortnight over eastern and central England was issued by the Meteorological Office, and was justified by results. The original division of weather into four types has been extended by the critical analysis of long series of daily weather charts, the most recent classification being that made by E. Gold,[1] and much material is now available for statistical study.

An understanding of British weather depends on an understanding of the causes which lead to the establishment and modification of weather types. We may carry the study a step further by referring to the conflict between "polar" and "equatorial" air, envisaged by the Norwegian meteorologists in their researches on cyclones; but a better insight into ultimate causes is given by the older conception of "centres of action," according to which the dominant factors in the pressure distribution are three: the area of low pressure which is generally found in the neighbourhood of Iceland or southern Greenland, and is termed the Icelandic minimum; the area of high pressure which occupies the eastern Atlantic near and south of the Azores, termed the Azores anticyclone; and in winter, the area of high pressure which is centred in Siberia and extends in a west-south-westerly direction towards the Azores anticyclone.

If we could forecast the position and intensity of these three centres of action during any month, we should be well on the road to true long-range weather forecasting. That is not yet the case, but a certain amount of information has been gleaned which encourages further research. The Siberian winter anticyclone appears definitely to be due to the extreme "continentality" with its low temperatures and hindrance to the outflow of air; it is, in fact, a "pool" of cold air. Such a continental anticyclone itself intensifies the cold of winter, and once formed is difficult to dislodge. There is nothing more favourable to the establishment of anticyclonic conditions than a covering of snow, and an extensive snowfall over northern or eastern Europe early in the winter may cause a persistent westerly extension of the Siberian anticyclone, influencing the weather of the British Isles for several months.

The other two centres of action are still more important, and they are intimately connected with each other. When pressure is high at the Azores it is generally low near Iceland, and vice versa; when the Azores anticyclone advances northward the Icelandic minimum generally does likewise, but there are exceptions to both these rules. There have been cases, notably February 1895, when the distinction between the anticyclone and the depression was wiped out, and for a whole month pressure was higher at Iceland than at the Azores. The existence of these two centres of action is connected in some way, not yet fully understood, with the general circulation of the atmosphere, but there can be no question that the details of their position and intensity are modified by local effects, and especially by variations of sea temperature, and in the case of the Icelandic minimum by the presence or absence of floating ice, and we

[1] London, Air Ministry, Meteorological Office. Geophysical Memoirs, No. 16. Aids to forecasting: types of pressure distribution, with notes and tables for the fourteen years, 1905–1918. By E. Gold. London, 1920.

have to broaden our survey to include these two factors.

The primary facts about the circulation of the waters of the North Atlantic Ocean are familiar to most people, and for our purpose can be generalised into two processes. First, a great mass of warm surface water is driven westwards near the equator by the Trade winds, ultimately being deflected northward by the coast of America and forming the Gulf Stream; secondly, this warm water is spread out south-east of Newfoundland, and is driven eastward by the prevailing winds towards the European coast. Consequently, any increase in the strength of the Trade winds should be followed after a considerable interval by a rise in the temperature of the sea north of Scotland. This has very little direct influence on the temperature of these islands, but it intensifies the Icelandic minimum and draws it south-eastward, causing low pressure and much cyclonic activity in the North Sea, with strong south-westerly winds over Holland, Germany, and Denmark, and northerly winds over Iceland. Thus, P. H. Gallé[2] found that when ships' observations showed an increased strength of the Trades during spring and summer, the following winter was warm over Holland and Germany, but cold over Iceland and Greenland. This refers to observations over the whole Trade belt. Unfortunately, direct observations of the strength of the North-east Trade are difficult to obtain, but we may employ instead the mean pressure at the Azores, which may be taken as a measure of the development of the North Atlantic anticyclone, with which the Trade wind is associated. The interval between the occurrence of high pressure at the Azores and of low pressure near the Faroes is about a year, which is the average time required for the completion of the oceanic circulation between these points.

The influence of floating ice on the pressure distribution is equally marked. The great ice-factory of the northern hemisphere is the Arctic Ocean north of the Eurasian coast, and delivery is effected by a current which sets from near Spitsbergen down the east coast of Greenland and round Cape Farewell. Each spring this current carries great masses of sea-ice, and in some years with strong north-westerly winds much of this ice is carried to the coasts of Iceland. From 1901 to 1919 there were 43 months during which ice lay off Iceland for more than five consecutive days, and in the majority of these months pressure in Iceland was more than 2 mb. above normal. The mean deviation of pressure from normal during the whole of the ice-days (to the number of 701) was +6·7 mb. Since there is no reason to suppose that the high pressure brings the ice, this result indicates conclusively that the ice and the cold surface water associated with it are effective in raising the pressure over Iceland and producing a northerly type of weather in the British Islands.

W. Weise[3] has recently made a further step. The ice takes about 4½ years to travel from the Arctic Ocean north of Siberia, where it is formed, to the East Greenland current, and he found that low temperature at Obdorsk and Turuchansk in autumn is followed after this interval by a large amount of ice east of Greenland, and vice versa. Thus an important factor in our spring weather is determined by conditions 4½ years previously in the north of Siberia.

The influences which control British weather are many and diverse, and it is not wonderful that the small fluctuations of the solar constant elicit no obvious response. Yet they can sometimes be traced; for example, at times of increased solar radiation (and many sunspots) the tracks of depressions appear to be on the average rather further south than with diminished radiation (and few sunspots). From 2 to 4½ years after sunspot maxima the Azores anticyclone tends to spread northward in summer over Spain and the Bay of Biscay, or even over the British Isles, giving conditions favourable to drought. Various other solar effects have been suggested in British weather, but none are definite enough for use in forecasting. The same conclusion must apply to "weather cycles." The search for the golden cycle in weather is curiously similar in its history to the search for the philosopher's stone—it has not been found, and we are more and more compelled to the belief that it does not exist; but in the search for it much information of value in other respects has been acquired. Periodicities in weather there undoubtedly are, but they are usually either so small in amplitude as to be of academic interest only, or they show baffling changes of phase and amplitude. Even the classical "Brückner cycle" of 35 years is only recognisable when we add the rainfall of ten consecutive years together, and its absolute uselessness for forecasting is shown by the position of the dry year 1921—one year before a maximum. The standard deviation from normal of a month's rainfall in London is about sixty per cent., while the variation attributable to the Brückner cycle is less than three per cent. A similar criticism applies to Sir William Beveridge's periodicities in the price of wheat.

Ocean currents and floating ice are thus the most important factors in British weather. Given a foresight of these two elements, we could make a reasonable guess at the general type of weather likely to prevail, though not the changes from day to day. Both ocean currents and ice are themselves also subject to modification by pressure distribution, and consequently we have a chain of cause and effect connecting a succession of months or seasons. We know the normal oceanic circulation and the normal pressure distribution. If in a given month we knew also the deviation of pressure from the normal distribution, we should be able to infer the abnormalities which will be produced in the oceanic circulation and hence to calculate the pressure deviations for the following month. If the process were sufficiently well understood we could carry our calculations forward long enough to give useful forecasts; at present the subject has scarcely reached even the experimental stage. A large statistical basis is necessary, and it is only within the last few years that this has begun to be supplied by the *Réseau Mondial*,[4] a compilation of monthly means of pressure, temperature, and rainfall over the globe.

Obituary.

MR. T. PRIDGIN TEALE, F.R.S.

In the death on November 13, at the age of eighty-two, of Mr. T. Pridgin Teale, medicine and sanitary science have lost a leader, and society has lost a very interesting man. For some generations the Teales had been medical practitioners in Leeds, and Mr. Pridgin Teale's father—of the same name—had likewise a very large consulting practice in surgery in and beyond the county of Yorkshire. The family were in part of Huguenot descent (Pridgin = Prujean), and to this strain no doubt Pridgin Teale owed much of his social charm and vivacity.

Of Pridgin Teale's eminence as a surgeon there is no need to speak; for the particulars of his professional work our readers will look to the medical journals; it is our place to speak of his work as a man of science, and especially as a reformer in sanitary practice and in economy of fuel. For twenty years he was president of the North-Eastern Branch of the Sanitary Inspectors' Association, and to that body he delivered many addresses full of that vigour and acute practical intelligence so characteristic of him. He was as ardent in teaching and persuasion as he was ingenious in suggestion and contrivance. In his well-known fire-grate constructions it is interesting to know that Mr. Teale was in intimate association, on the æsthetic side, with Mr. de Morgan. Since the days of Mr. Teale's most active life many changes have passed over sanitary science, but among the earnest and inventive pioneers in these subjects, Pridgin Teale's name will scarcely be forgotten.

To his friends Pridgin Teale was one of the most attractive of men. Absolutely sincere, unselfish, blithe, and enthusiastic, he was one of the most charming of companions and the most loyal and generous of friends.

C. A.

BRIGADIER-GENERAL G. E. PEREIRA.

The death, at the age of fifty-eight, of Brigadier-General G. E. Pereira is a severe loss to Asiatic geography, owing to the wide range of his Chinese travels. He served at home in the Grenadier Guards until 1899, when he was sent on special service to China and was attached to the Chinese regiment in the British Protectorate of Wei-hai-Wei. He accompanied the Japanese army in Manchuria in 1904, and was military attaché at Peking from 1905–10.

General Pereira made good use of the intimate knowledge of the Chinese and fluent mastery of the language acquired during these services, in long journeys in China and Chinese Turkestan. His best known expedition was his walk overland in 1921 from Peking to India across Tibet and through Lhasa. In this journey he obtained much valuable information, especially accurate heights of some of the passes in eastern Tibet. In 1922 he started on what was intended to be his last expedition, and crossed from Bhamo in Burma by the chief road through south-western China to the Yangtze at Sui-fu. He descended the Yangtze by boat, and visited the island of Hainan in connexion with his ethnographic studies. He returned up the Yangtze to Yunnan-fu, whence in company with Dr. Thompson he set out for south-eastern Tibet in the hope of reaching Amnemachin, which is thought to be the highest peak in the Kwen-lun Mountains, near the upper bend of the Hwang Ho. He had seen this mountain in 1921, and his descriptions led to the report that it might be the highest mountain in the world. Considering, however, its geographical relations, General Pereira's own estimate of 25,000 ft. is probably more correct. The two travellers reached A-tun-tze last August, and letters from Pereira were full of enthusiasm and hope for a successful journey to the Kuen-Luns. He reached Yakalo, the French mission station, well known as the residence of the Abbé Desgodins, by the Salt Mines on the Mekong. His last letters were dated there on September 15, and his fatal illness was probably on the borders of autonomous Tibet.

General Pereira had published but little, and those interested in Chinese geography hoped that he would devote his leisure to a general account of his extensive travels. He was an enthusiastic adherent of the traditional view that the Himalaya end in Assam, and some of his last letters from A-tun-tze re-stated his views on that problem. Amongst his scientific contributions was obtaining for the Natural History Museum its second Chinese skin of the Panda, one of those interesting animals living in southern China the affinities of which are American.

MR. W. H. DUDLEY LE SOUËF.

The October issue of the *Victorian Naturalist* contains an appreciation of the life and work of Mr. W. H. Dudley Le Souëf, Director of the Melbourne Zoological Gardens, who died on September 6, at the age of sixty-six. Mr. Le Souëf was a prominent member of the Field Naturalists' Club of Victoria, and his extensive travels over the Australian continent studying the habits of or collecting native animals, birds, etc., provided material for numerous papers which he contributed to the Club. In most of these the main interest centred on the birds, but other branches of natural history were not neglected. He compiled a list of Victorian reptiles published in the *Victorian Naturalist* of 1884, and was the author, with Mr. A. H. S. Lucas, of two standard works, "The Animals of Australia," and "The Birds of Australia." In another volume, "Wild Life in Australia," he brought together the accounts of his many expeditions which had appeared from time to time in the *Victorian Naturalist* and the *Emu*, the organ of the Australasian Ornithologists' Union, of which he was one of the founders. His interest in Australian ethnology led him to take part also in expeditions to King Island, the Kent Group, and to Albatross Island. Mr. Le Souëf was an enthusiastic student of Nature, who was always willing to bring natural history before an audience, generally illustrating his lectures by lantern slides from his own photographs. For many years he was Assistant Director of the Melbourne Zoological Gardens, and in 1902 he was made Director, in succession to his father. Under his care the Gardens have become the most important collection oi animals in Australia.

Current Topics and Events.

The satisfaction that has been expressed with the recommendation that the Imperial Institute should be maintained at South Kensington is accompanied with a still wider regret that the collections are to be abolished to make room for the War Museum. The Committee which has made these recommendations appears to regard the collections as of use only as trade samples and accepts the view that those at the offices of the Australian agencies in the Strand are more useful. The Imperial Institute collections, however, are much wider in their scope. The Imperial Conference urged the need of extended teaching of the geography of the Empire, and the Imperial Institute collections are unique as an illustration of the life, resources, and scenery of every country within the Empire. It is the only collection in Great Britain which can be compared with the geographical museums of Germany. The Institute is naturally of less value to the great Dominions, which can afford well-equipped research departments and show rooms in the centre of London, than it is to the smaller colonies and dependencies. Hence Australia in pre-War times contributed to the Institute only 500*l*. per annum against 1000*l*. given by Ceylon. The smaller dependencies, and especially those in the tropics, are in increasing need of the help that may be given by an Imperial co-operative organisation. Emphatic testimony to the educational value of the galleries is quoted in the minority report, in which New Zealand offers an increased subsidy if they be maintained. The collections are also condemned on the ground that they are only of value to people in London, a drawback shared by all national metropolitan institutions. The leasing of the galleries is recommended as a means of raising 8000*l*. per annum for the general revenues of the Institute. For this amount costly collections made and presented by governments and individuals are to be scrapped, and a building largely raised by private subscriptions, and the site given by the Commissioners of the 1851 Exhibition for an Imperial scientific institution, are to be handed over to a War Museum. Mr. H. M. Lidderdale, Secretary to the executive council, has been appointed Acting Director pending the re-organisation of the Institute.

The *Times* in its issue for November 28 publishes a very interesting photograph showing the eggs of a deinosaur against their natural background; in fact, they can scarcely be said to have been removed from the beds in which they were so happily preserved. The discovery, made by Mr. Roy Chapman Andrews when exploring a desert region in Mongolia for the American Museum of Natural History, has excited much interest among naturalists, and it is now authoritatively announced that surplus specimens, after complete examination and description, will be disposed of for about 400*l*. apiece. This price cannot be regarded as excessive, and the sum realised will be used towards defraying the expenses of the expedition. When placed on exhibition in a public museum, the egg should certainly be accompanied by a copy of the photograph utilised by the *Times*, showing its companions practically *in situ*. By that time, the scientific report on the occurrence will be available, and will no doubt contain all necessary illustrative material. The relationship of the deinosauria to the crocodiles and to the birds makes the discovery of their eggs not in itself surprising; but the fact that one egg at least contains an embryo furnishes hope for the revelation of new links in the chain of reptilian descent. Public interest should now be still further attracted to the fine collection of deinosaurian remains in the Natural History galleries of the British Museum at South Kensington, and to the admirable guide recently issued in connexion with them (see NATURE, April 29, 1922, p. 561). We can already conceive a wall-painting in the American Museum of Natural History, depicting the Gobi region in Mesozoic times, with a maternal deinosaur affectionately bringing up its young.

Among the scientific bequests of the late Hon. N. C. Rothschild, whose death was referred to in NATURE of November 10, p. 697, those relating to the distinguished naturalist's great collection of Siphonaptera, or fleas, are of special interest not only to entomologists, but also to students of insect-borne disease. Including as it does some 40,000 specimens of fleas in alcohol, and 3550 microscope slides, representing in all about 600 species, the collection must prove of priceless value to all who in future years desire to investigate questions connected with the epidemiology of bubonic plague, and its transmission by various species of fleas. Although actually presented to the Trustees of the British Museum in 1913, the collection was, by arrangement, allowed to remain temporarily in the possession of its founder; and even now a further period will elapse before the specimens, which occupy eight large cabinets, are finally installed at South Kensington. During the interval, the catalogue of the collection, which will include an illustrated description of every species represented in it, will be completed by Dr. K. Jordan, the value of whose work on Siphonaptera, as collaborator with the late Mr. Rothschild, has obtained world-wide recognition. To provide for the permanent maintenance of the collection, Mr. Rothschild has left to the Trustees of the British Museum 10,000*l*. upon trust, in order that the income thereof may be utilised to pay the salary of a qualified custodian. In the testator's will, the request is made that Mr. F. J. Cox, his assistant, should be employed in the latter capacity. Mr. Cox is known to possess a wide knowledge of Siphonaptera, and it was by him that, at the instance and expense of Mr. Rothschild, the small collection of fleas already belonging to the Museum was catalogued and arranged some years ago.

It is rumoured, but we hope without foundation, that a suggestion has been made to the Albanian Government that exclusive rights of excavating in Albania should be assigned to French archæologists, with possession of a considerable proportion of the finds. Although no one would wish to question the

right of the Albanian Government to make such arrangements as it thinks best for the investigation and preservation of the antiquities of that country, such a course as is proposed cannot, on the face of it, be considered in the best interests of science. It is not intended to cast any reflection upon the ability or disinterestedness of the archæologists of France or any other country; but scientific investigation should be free from the trammels of nationality. The position in the Balkans is already one of some difficulty, as recent legislation in Greece has restricted the number of excavations which will be permitted to the Schools of Archæology beyond those already in being, while in Serbia concessions for excavation are not to be granted at all to foreigners. In view of the great importance of the whole Balkan area for archæological studies, any further restriction, such as this proposal to confine excavation in Albania to scientific workers of one nationality only, would be peculiarly unfortunate.

A NECESSARY consequence of any increased interest in, and consideration of, science and scientific workers by the general public will be an examination of the part that science has played in producing the bad, as well as the good, features of modern civilisation. It is natural that the advance of science in penetrating the mysteries of the universe, or its essential part in promoting the development of material resources and making possible mechanical production of commodities necessary for peace or war, should be a satisfactory subject of contemplation to the scientific worker. But the public will not only ask about the responsibility of men of science for the development of fertilisers or of poison gases, but also what they think is the relation between the present possible level of productivity and the present destitution in every civilised state. Prof. F. Soddy anticipated such questions as these in his "Cartesian Economics" lectures, and he developed them in a lecture entitled "The Inversion of Science," given at the Guild House, Eccleston Square, on Thursday, November 29. He pointed out the strange coincidence of the perfection by James Watt in 1774 of the steam engine which was to revolutionise all the methods and possibilities of production, and the elaboration in 1776 by Adam Smith in "The Wealth of Nations" of a system of economics founded on the conditions prevailing in the pre-scientific stage of society, which has nevertheless continued to be applied, with the result of an almost unlimited capacity for production that cannot be exercised because of a completely erroneous standard of values. Prof. Soddy held that wealth must cease to be reckoned by any artificial standard, whether of gold or of the arbitrary judgment of financial magnates, and be calculated on the actual or potential production of the necessities of life.

DURING the War many unsuccessful experiments were tried to bring to a stop from a distance motor cars or aeroplanes. According to an announcement in *La Liberté*, a French engineer has given practical proof of an invention that enables him to stop the motors of an aeroplane or a motor car at a distance of about 50 yards. It is quite possible that the emission of very strong Hertzian waves might interrupt the proper functioning of magnetos at this distance, but we cannot infer that it would be equally simple to stop the motor of an aeroplane in full flight at a distance of a few miles. In any event the problem of protecting the magnetos of the motors from interference by suitably screening them would be an easy one.

THE transmission of a broadcast programme across the Atlantic by the British Broadcasting Company in the early hours of November 26 was a fairly successful one. From 3 to 3.45 A.M. the B.B.C. sent out a concert from London on its normal wave length and power. This was broadcasted again simultaneously by the other British stations, each on its own wave length. All the stations, with the exception of Birmingham, Manchester, and Aberdeen, were clearly heard in America. During the winter months transatlantic telephony and broadcasting is generally successful during night-time. During the early hours of November 27, American stations broadcasted. Several of them were heard in different places in Great Britain, but the atmospherics unfortunately were very much in evidence and so the experiments could not be regarded as successful. On December 22 the Radio Society of Great Britain will make experiments, in conjunction with American amateurs, between 1 and 3 A.M. The G.P.O. has given permission to some amateur stations to increase their normal power (10 watts) to 1000 watts for these tests.

WE regret to note an announcement in the December issue of *Discovery* that this number is to be the last to appear. All who are interested in the spread of a knowledge and appreciation of the results of scientific investigation among the general public will regret the disappearance of this publication. Since it was founded in 1920, *Discovery* has consistently maintained a high standard of scientific accuracy, and has placed before its readers in clear and non-technical language a large number of articles, necessarily varying considerably in merit, which were selected with the express intention of keeping readers abreast of the latest movements of thought in the scientific world. It was started under favourable auspices at a time when the events of the War had impressed upon the public mind the value of scientific research from a practical point of view. Its committee of management consisted of representatives of the most important of the scientific and learned societies, and amongst its contributors it has numbered some of the most prominent of the scientific men of the day. Yet notwithstanding these facts, and notwithstanding a wide appreciation of its merits as a popular scientific publication, it has failed through lack of public support.

IT was stated in our issue of December 1, p. 803, that the Science Collections from the Western Galleries of the Science Museum, South Kensington, had been removed to three unfinished galleries of the new Science Museum building, and that one of these galleries has now been thrown open to the

public. In this are the following exhibits: *Astronomy*: Sundials, astrolabes, and similar instruments, transit instruments, equatorials, astronomical photographs, telescopes, original apparatus and instruments made or used by the Herschels. *Surveying*: Instruments illustrating the development of the theodolite and level, including Ramsden's three-feet theodolite. *Meteorology*: Almost the whole section as previously exhibited, with a recent acquisition—a plaster cast of an early Korean rain-gauge. *Chemistry*: Historical apparatus and specimens, including apparatus of Faraday and Graham; Hartley's original spectrograph; replica of Priestley's original oxygen apparatus; models of chemical works. *Optics*: Microscopes, telescopes, spectacles, polariscopes, early moving-picture devices. *Sound*: Early talking machines, including Edison's original phonograph; instruments used in sound-ranging. *Botany*: Models of flowers. About eighty per cent. of the Science Collections will be in storage until more space becomes available.

IT is announced in the *Times* that 13,000,000 francs (more than 160,000*l.*) was collected for the benefit of French scientific laboratories on the occasion of "Pasteur Day."

DR. F. W. WILLWAY, J.P., Newfoundland, provides an interesting running comment on the film production "Nanook of the North" at the Polytechnic Hall, London. His talk, based upon personal experience, takes the place of the customary captions and makes more real this untouched and unrehearsed picture story of the actual life of the Eskimos on the west side of Ungava. The musical accompaniment to the closing scene, an Arctic blizzard, enhances the effect so strongly that the impression of desolate brutality lasts long after the vision ceases. Mr. Flaherty's picture is assuredly one to see.

RECENT additions to the National Portrait Gallery include the portraits of three former fellows of the Royal Society, namely:—Sir George Howard Darwin, K.C.B. (1845-1912); Sir Henry Charles Englefield, Bt. (1752–1822); and Mr. Philip Metcalfe (1735–1818).

THE Huxley medal of the Royal Anthropological Institute for the year 1923 has been awarded by the Council to Dr. E. Sidney Hartland, the well-known authority on folklore and the author of "Primitive Paternity" and other pioneer works on social anthropology. Unfortunately, the state of Dr. Hartland's health in the earlier part of the year has precluded him from preparing the Huxley memorial lecture, which it is usual for the recipient to deliver on the occasion of the presentation of the medal. The Huxley medal for the year 1924 has been awarded to Dr. Henri Verneau, of Paris, by whom the Huxley memorial lecture for 1924 will be delivered in November next.

MR. JOSEPH BARCROFT has been elected Fullerian professor of physiology at the Royal Institution in succession to Sir Arthur Keith. M. le Duc de Broglie, Dr. C. L. Guillaume, and Profs. Debye, Einstein, Groth and von Laue have been elected honorary members of the Institution.

THE British and Foreign Sailors' Society, Incorporated, The Passmore Edwards Sailors' Palace, 680 Commercial Road, London, E14, supplies Christmas parcels regularly to more than 600 lighthouses and lightships; in addition it maintains 650 ships' libraries afloat, and parcels of literature and magazines are regularly placed by the Society on outgoing ships. Gifts of literature, books, magazines, etc., would be welcomed at the Society's headquarters.

THE following officers and committee of the University of Durham Philosophical Society for the Session 1923–24 have been elected: *President*: Rt. Hon. Earl of Durham; *Vice-Presidents*: Hon. Sir Chas. A. Parsons, Sir Theo. Morison, Dr. T. H. Havelock, Dr. H. Stroud, Prof. H. Louis, and Mr. W. Hall; *Committee*: Commander C. J. Hawkes, Dr. H. V. A. Briscoe, Dr. G. R. Goldsbrough, Dr. J. A. Smythe, Mr. S. H. Collins, and Mr. Rhys Thomas; *Editor*: Dr. G. W. Todd; *Librarian*: Dr. F. Bradshaw; *Secretaries*: Mr. J. W. Bullerwell and Mr. B. Millard Griffiths. The second edition of the "Dr. Theodore Merz" Memorial Number of the Proceedings is now in the Press.

AT a meeting held in June last, it was decided to establish a memorial to the late Prof. A. D. Waller and Mrs. Waller in the form of a fund for scientific research to be administered by the Council of the London (Royal Free Hospital) School of Medicine for Women (NATURE, June 16, p. 818). Prof. Waller was also lecturer in physiology at St. Mary's Hospital Medical School for nineteen years, and it is now proposed to establish an additional memorial in the form of a research room, to be known as the Waller Research Laboratory, in connexion with the Physiological Department. A large and distinguished committee of British and foreign scientific workers has been formed to carry out the memorial schemes. Subscriptions marked accordingly if they are intended for the St. Mary's Hospital Medical School memorial, should be sent to the hon. treasurer of the fund, Prof. J. Mellanby, St. Thomas's Hospital Medical School, London, S.E.1.

MR. W. H. HOFFERT has been appointed by the Council of the University of Leeds to be research chemist to the Joint Research Committee of the National Benzole Association and the University in succession to Prof. E. C. Williams, who resigned his appointment on September 30, on his election to the Ramsay memorial chair of chemical engineering in the University of London. Mr. Hoffert took a first class at Oxford in 1914, in the final honour school of natural science (chemistry), and was also awarded a research scholarship at Jesus College. In 1919 he was appointed to a research fellowship of the Salters' Institute of industrial chemistry. More recently, he has worked as research chemist to a Lancashire firm engaged in the coal tar industry, and has also had experience at H. M. Fuel Research Station, Greenwich. Mr. Hoffert will work in the Department of Coal Gas and Fuel Industries of the University of Leeds, under the supervision of Prof. J. W. Cobb, particularly in connexion with the possibilities of increasing the home supplies of motor spirit from coal.

Prof. A. Smithells resigned in June last the chair of chemistry in the University of Leeds, which he had held with much distinction since, in 1886, he was appointed in the old Yorkshire College. His part in promoting the foundation of the University of Leeds, in bringing technological studies into relation with other work of the University, in furthering chemistry and its technical applications, and in linking up the University with the community it serves, is well worthy of commemoration, and a committee has been appointed to raise funds for this purpose. With the money obtained it is proposed to have a portrait of Prof. Smithells painted for presentation to the University, and to establish in his name, and by his advice, a fellowship or scholarship within the University—two means by which his connexion with the University will be handed down to posterity. Subscriptions, made payable to the treasurer of the Smithells Fund, should be forwarded to Mr. A. G. Lupton, Beechwood, Roundhay, Leeds.

Mr. Paul C. Standley, associate curator of plants in the National Museum, Smithsonian Institution, has left Washington for Panama, where he will make investigations of the plant life of the Canal zone and its immediate vicinity. This work, undertaken in co-operation with the Department of Agriculture, has for its object the preparation of a descriptive and illustrated account of the plants occurring in the region. Botanical exploration of the Isthmus of Panama was begun about 1790 by Luis Née, a Frenchman, who accompanied the famous navigator Malaspina on his voyage around the world. A very extensive collection also was obtained by the Smithsonian Biological Survey of the Panama Canal Zone in 1910–11, and more recent collectors have forwarded to the National Museum noteworthy collections, so that at the present time more than 2000 species of plants are known from the region. From a botanical point of view the Isthmus has not been thoroughly explored, however, and it is probable that further work there will increase this number by 50 per cent. Panama is particularly rich in palms, and has a good representation of orchids and ferns. After spending about two months in Panama, Mr. Standley will go to Costa Rica to make further collections of plants.

In the course of his presidential address to the Institution of Civil Engineers delivered on November 6, Sir Charles Langbridge Morgan had a good deal to say in encouragement of the numerous young men seeking to enter the civil engineering profession, often with an equipment of scientific knowledge and general education which would have been regarded as exceptional in his own early days. Sir Charles traced the development of transportation in Greater London during the past fifty years, and gave a number of interesting tables relating to local railways, suburban sections of main-line railways, tramways, omnibuses, etc.; these carried a total of 1,036,806,934 passengers in 1900 and 3,125,321,122 in 1920. From the developments which have taken place, and others projected, Sir Charles refuses to believe that the profession of civil engineering has entered upon a permanent decline. No one can deny that there is reason for temporary discouragement of young men who are at present confronted with extraordinary difficulty in obtaining work. If the older members were to shut their eyes to the seriousness of the position of junior members of the profession, they would be failing in their duty. It is the part of such bodies as the Institution of Civil Engineers to do all that can be done by organisation, encouragement, and co-operation to hasten that recovery of the whole profession to which all look forward.

A guide, with code and instructions, relative to wireless weather telegraphy in Great Britain and the countries of Europe and North Africa, has recently been issued by the Meteorological Office of the Air Ministry (M.O. 252, H.M.S.O. 2*s*. 6*d*. net). The details of the meteorological messages transmitted by the several countries are arranged on a uniform plan. Times of sending are explained and the meanings of the symbols used, so that any one having the suitable equipment can receive both reports and forecasts. The issue of particulars of the messages from different countries is brought up to date, and amending notices will be issued as required from time to time. Purchasers of this new edition of the guide will be informed when fresh notices are issued if they notify the Director of the Meteorological Office that they desire to receive the information. Use can be made of messages transmitted to the Meteorological Office by the aid of which the daily weather reports and forecasts are prepared for the Press and the general public. In addition to this a "general inference" is issued at 9.15 A.M. and 8 P.M. based on observations taken at numerous local and foreign stations as well as over the Atlantic. An example is given of the "general inference," and it is stated that "the first transmission of this report is made at ten words a minute for the benefit of amateurs." The message is in plain language, and can be readily understood by others than meteorologists. The general inference is in effect a picture in words from which a general survey of the prevailing and controlling weather conditions can be obtained.

The annual reports of the Smithsonian Institution of Washington contain not only full statements of the activities of the Institution during the year, but also a large general appendix which consists of a miscellaneous collection of memoirs covering a wide range of subjects. This appendix forms fully three-quarters of the volume for 1921, which has recently been issued, and it provides a valuable collection of noteworthy scientific papers issued during the year. Many of the items are original and by American workers, while others are translations and reprints. Among the latter are: "Cosmogeny and Stellar Evolution," by Mr. J. H. Jeans, from Nature of June 30 and July 7, 1921; and "The Age of the Earth," by Lord Raleigh, Prof. W. J. Sollas, Prof. J. W. Gregory, and Dr. Harold Jeffreys, from Nature of October 27, 1921. The translations included are: "The Diameters of the Stars," by A. Danjon, from *L'Astronomie* of November and December 1921; "The Historic

Development of the Evolutionary Idea," by Branislav Petronievics, which is a translation of the first chapter of Petronievics' work, "L'Évolution universelle"; "The Heredity of Acquired Characters," by Prof. L. Cuénot, from the *Revue Générale des Sciences* of October 15, 1921; "The Indian in Literature," by Herman F. C. ten Kate, from papers published in the Dutch magazines *De Gids* (1919) and *De West-Indische Gids* (1920); and "The Alimentary Education of Children," by Prof. Marcel Labbé, from the *Revue scientifique* of September 10, 1921.

THE Christmas lectures at the Royal Institution, which are to be delivered this year by Sir William Bragg, will be published afterwards in book form by Messrs. G. Bell and Sons, Ltd., under the title, "Concerning the Nature of Things."

WE have received from Messrs. Ogilvy and Co., 18 Bloomsbury Sq., W.C.1, the British agents, new editions of Leitz catalogues of microscopes and dissecting microscopes and magnifiers. Microscopes, objectives, magnifiers, and other apparatus of all types are listed, and the purchaser has a wide choice as regards both elaboration and price. In addition, some interesting and instructive details are given of the general properties of objectives and eyepieces and of their classification.

MESSRS. C. BAKER, of 244 High Holborn, London, W.C.1, have recently issued a new classified list of second-hand scientific instruments (No. 79) which they have for disposal. The catalogue contains a large assortment of apparatus, and particularly of microscopes, telescopes, and their accessories. Among the astronomical telescopes (refractors) are a 12 in. equatorial and a 7¼ in., both by Cooke, and an 8 in. by Grubb. A wireless department has been established by Messrs. Baker, and a list of the apparatus available, all of which is new, has been added to the catalogue of second-hand instruments.

IN the Year-book of the Royal Society of Tropical Medicine and Hygiene, Session 1923-24, recently issued, an account with illustrations is given of the Chalmers and Manson memorial medals of the Society. The former, founded by a donation from Mrs. Chalmers, is in memory of Dr. Albert J. Chalmers; the latter, by a surplus of a portrait fund, is in memory of Sir Patrick Manson. The Chalmers medal is awarded biennially, and this year has been presented to M. E. Roubaud, of the Pasteur Institute, Paris. The Manson medal is awarded triennially, and has been presented to Sir David Bruce.

THE Cambridge Philosophical Society is to publish, through the Cambridge University Press, as separate supplements to the Proceedings, translations of Dr. Niels Bohr's present series of papers "On the Application of the Quantum Theory to Atomic Structure," Part I. of which has already appeared in the *Zeitschrift für Physik*, vol. xiii. (1923). The translation of Part I. will be closely followed by a similar translation of Part II., which it is hoped will appear simultaneously with the German version. Part I. will deal with the fundamental postulates of the quantum theory, and Part II. with the theory of series spectra.

ERRATA.—In our issue of November 10, p. 704, in the Research Item on the Early Proboscideans, for "Schlasser" read "Schlosser"; December 1, p. 806, in the Research Item on the Cheiropterygium in Amphibia, line 3 from end, for "its first 'i'" read "its first 'e.'"

Our Astronomical Column.

THE DECEMBER METEOR SHOWER.—Mr. W. F. Denning writes: "This annual display of meteors may be expected on the night of Wednesday, December 12, when it will probably reach its maximum intensity. The shower is visible, though it supplies very few meteors, during the first week of December, and the radiant point appears to be a moving one like that of the August Perseids. As the moon will be absent from the evening sky during the early part of December this year, it will be possible to watch the oncoming and development of the shower if we get sufficiently clear weather. The position of the radiant on Dec. 1 will be about $98° + 34°$; on Dec. 5, $104° + 33°$; on Dec. 10, $110° + 33°$; and Dec. 15, $116° + 32°$.

"Occasionally, the shower proves a rich one and supplies about 40 or 50 meteors per hour; but the most abundant displays are usually witnessed in the morning hours, as the radiant is then at a greater altitude than in the earlier part of the night. In 1920, on Dec. 12, the shower returned with considerable strength, though it does not appear to have been well observed, in consequence of unfavourable weather.

"The individual meteors of this stream are moderately swift and short, and as they do not often leave streaks or trains they are rather difficult to record accurately. The radiant point is therefore not often determined as correctly as that of the Perseids or Leonids."

COMPANION TO OMICRON CETI.—The interesting variable Omicron or Mira Ceti has been found by Prof. R. G. Aitken (Harv. Coll. Obs. Bull. No. 792) to have a close companion, at distance 1·01″, position angle 132·3°. The companion was bluish in colour, and on October 19 was fully half a magnitude fainter than the variable. The tardy discovery of a companion to such a well-scrutinised star is remarkable, and suggests that the distance may be increasing. It will doubtless be carefully followed in the hope of obtaining an orbit, which would determine the mass of Mira. It is possible, however, that the pair is an optical, not a physical, double.

PROPOSED OBSERVATORY IN NEW ZEALAND.—The Bulletin of the New Zealand Astronomical Society announces that the University of Yale has offered a large telescope for astronomical observation in New Zealand, provided a good site can be found, the conditions of seeing to be tested with a telescope of 6 or 7 in. aperture, in a similar manner to the tests made before setting up the Victoria telescope in British Columbia. The New Zealand Government has been approached to grant funds for this examination, and has given a hopeful reply. The difficulty appears to be to combine good seeing with convenient access. Most of the towns are near the coast, and the seeing is poor. Various sites are suggested by amateur astronomers, and it is greatly to be hoped that the scheme may go through.

Research Items.

The Causal Organism of Braxy in Sheep.—There has been much dispute regarding the essential symptoms and the causal organism of braxy. What may be called the old school considered the disease to be due to an anaerobic, motile, spore-bearing bacillus, giving rise to an inflammatory condition of the fourth stomach. But the latest review of our present state of knowledge, by Dr. J. P. McGowan (*Centralbl. f. Bakteriol., Parasit., und Infektionskr.*, Jena, Bd. 91, 1923), shows that, in face of the criticism of continental workers and of the author himself, this view must be abandoned, for feeding or inoculation with the alleged causal organism fails to produce braxy. It would also appear that the symptoms usually considered to be those of braxy are in reality very rapid post-mortem putrefactive changes. Examination of very fresh carcases shows the abundant presence in pure culture of *Bacillus bipolaris septicus ovium*, inoculation with which reproduced the disease; and this would indicate that braxy is a hyperacute form of hæmorrhagic septicæmia. Sheep are predisposed to attack under conditions of lowered resistance, often dependent upon climatic factors, such as the presence of a large quantity of frosted grass in the food, or exposure to severe day and night fluctuations of temperature. Sheep which are feeding poorly seldom suffer from the disease, and to this fact the author attributes the success of the well-known pig-dung drench and of the "vaccines" prepared from non-causal bacilli, since both treatments throw the sheep seriously out of condition.

Insulin.—The chemisty of insulin is described in an article by Mr. Norman Evers in the *Chemical Age* for November 3. So far back as 1885 Mering and Minkowski noticed that complete extirpation of pancreas from dogs was followed within a few days by diabetic symptoms similar to those observed in human beings. Lepine suggested that the pancreas gave some secretion which controlled carbohydrate metabolism, and this view gained ground. Schafer suggested the name "insuline" for the secretion produced by certain groups of small cells in the pancreas. Many attempts were made to prepare an extract of the pancreas which on injection would reduce the blood sugar of a diabetic patient, but it was left for Drs. Banting and Best, working under Prof. J. J. R. Macleod at Toronto University, to crown these efforts with success. Mr. Evers describes the original method of extraction in some detail, and considers the subsequent improvements; he also treats of the purification, chemical properties, and of the other sources of the substance. Apparently, for the present, ox and pig pancreas are the only available economic sources. It will be recalled that an article by Prof. J. J. R. Macleod describing the action of insulin appeared in Nature of October 27, p. 625.

Tropical American Ascomycetes.—Among the Ascomycetes of Tropical America are several puzzling forms of Discomycetes, which in habit recall rather the Basidiomycetous genus, Auricularia. Just before his death the late Prof. Durand had revised a number of these forms, and his findings have been published by Dr. Roland Thaxter, with some notes and two plates of figures added. The long-established genus, Midotis Fr., is now clearly characterised for the first time, whilst some other curious species, including some previously grouped under Cordierites Mont, are now placed in a newly formed genus, Ionomidotis Durand. Seven species of this new genus are described, and a key supplied for their identification.

Control of Disease in the Palmyra Palm.—Something of the problem involved in carrying out remedial methods in phytopathology is to be seen in the report by W. McRae, appearing in the Memoirs of the Department of Agriculture in India, volume 12, No. 11, July 1923. In 1905 Dr. E. J. Butler identified *Phytophthora palmivora*, Butl., as the cause of the serious disease of the Palmyra palm, *Borassus flabellifer* Linn., occurring in the Madras Presidency. This palm is of great importance to the native community both for its fruit and for its use as the source of a fermentable liquid used in the preparation of toddy. For the latter purpose the leaves at the apex of the shoot are cut. Older leaves are sometimes cut also for use either as fuel or as a source of fibre. Control of the disease has involved the cutting, removal, and burning of the green tips of diseased trees and then, as experience showed it possible, the removal of outer diseased leaves from less severely affected trees, which then frequently recovered from the disease. The author concludes that, during the fifteen years in which the control operations which he reviews have been in progress, some three-quarters of a million palms have been saved, and he affirms definitely that the disease has been reduced from a grave menace in 1908 to a controlled problem at the present time. The operations, carried out by native workers under the supervision of a special staff recruited from the Revenue Branch of the District Administration, are estimated to have cost 20,000*l*. for the period 1916–1921. Until the application of the Pest Act, everything had to be done with the acquiescence and co-operation of the villagers, the result being so careful an attention to propaganda and education in the reasons for remedial measures that during the first two years' operation of the compulsory clauses contained in the Pest Act only one prosecution has proved necessary.

The Theory of Isostasy.—At the meeting of the Royal Geographical Society on November 12, two papers discussing the theory of isostasy from very divergent angles were presented. The briefer one, "Doubts and Suggestions on Terrestrial Isostasy," by Captain Alberto Alessio, is critical of Hayford's method of treating Pratt's hypothesis: his assertion that the field of force of gravity, being observed only at a limited number of points, can be produced in an infinite variety of ways by appropriate distributions of density may be assented to; but he brings forward no arguments of sufficient weight to explain away the value of Hayford's simple general hypothesis as to the distribution of density under mountain or oceanic regions, as a means of accounting for variations in the gravitational field. The second paper, on "Abnormal Densities in the Earth's Crust disclosed by Analysis of Geodetic Data," is by Prof. W. Bowie, of the United States Coast and Geodetic Survey, who has continued Hayford's isostatic researches. It is a valuable and interesting résumé of the present state of the theory, indicating both its many successes and the extent to which it is to be regarded as a simplification—for purposes of preliminary analysis and computation—of the probable real facts. The anomalies or differences of the observed gravity data from the values calculated by Hayford's method are shown to be much less than those from the values calculated by Bouguer's method, in which no account is taken of the isostatic compensation. It is also shown that the Bouguer anomalies increase rapidly for elevated stations, while the "isostatic" anomalies show a purely normal accidental distribution. Even so, a considerable class

of cases in which the isostatic anomalies suggest decided departures from isostatic equilibrium can be reasonably accounted for by what may be regarded as a second approximation to the facts; the simple Hayfordian theory is that the compensating excess or defect of density is distributed uniformly throughout a column of a certain depth, independent of locality. Prof. Bowie has shown that in many cases there is geological evidence for the existence of heavier or lighter rocks (as the case may be) nearer the surface, and that these are capable of accounting for many of the anomalies referred to, without supposing the isostatic compensation to be incomplete.

CARBONISATION OF COAL.—The Fuel Research Board has issued a report (Technical Paper No. 8) on "The Steaming of Wigan Arley Coal in Vertical Gas Retorts" (H.M.S.O., 9*d.* net). It sets out the results which were obtained when this particular coal was carbonised with gradually increasing quantities of steam in the Glover-West vertical retorts of the Fuel Research Board's experimental station at Greenwich. The coal is one largely used for gas-making in Lancashire, and the tests on it were carried out "at the request of the Preston Gas Company, the Wigan Coal and Iron Company, Ltd., and Messrs. West's Gas Improvement Company, Ltd., these firms combining to bear the cost of 300 tons of coal for the purpose." A large amount of detail as to the results obtained finds its place in the text of the report, and particularly in tables given at the end, from which it is plain that an attempt has been made to secure as much information as possible during the tests for the guidance of gas engineers who may be thinking of using this coal. It is interesting to note that some data have been acquired for the fuel consumption, as reported thus: "The amount of heat required per ton for the carbonisation of this coal, including the sensible heat in the products, varied from 13·0 therms with 5 per cent. steam to 18·25 therms with 20 per cent. steam. The intermediate points were not obtainable owing to the amount of heat which was taken up by the setting when only three retorts were in use being unknown."

TEMPERATURE-MEASURING INSTRUMENTS.—A useful booklet of 71 pages has been issued by the Cambridge and Paul Instrument Company, in which a concise account is given of the various temperature-measuring instruments made by this firm. A perusal of its contents shows that the number of useful devices applicable to the measurement of temperature is continually increasing, so that the user has now a much wider choice than heretofore. Descriptions are given of dial and index thermometers, the latter being provided with an electric alarm attachment for ringing a bell when the temperature differs from that at which it is desired to work. With both these types continuous records may be taken on charts by means of a moving pen. In connexion with platinum resistance thermometers, direct-reading indicators for any assigned range are provided, in which the movements of the pointer depend upon the extent to which a Wheatstone bridge is thrown out of balance by the varying resistance of the platinum at different temperatures. Thermo-electric pyrometers, with base-metal and rare-metal couples and suitable indicators and recorders, are described; a form used for measuring surface temperatures, and methods of cold-junction control, being of special interest. Amongst radiation and optical pyrometers, a description is given of a recent pattern of the disappearing filament type, capable of reading to 2100° C. A new feature is the introduction of devices for the automatic control of temperatures, either of gas or electric furnaces or tanks of liquids. Control is effected from the indicator by means of a relay, which comes into action when the required temperature is reached, and operates a mechanism which regulates the supply from the source of heat. The instruments described under this head represent a distinct advance in temperature-measuring appliances.

"FISHING" IN OIL-WELL DRILLING.—Fishing is a term employed by the driller to cover a multitude of different operations connected with the drilling of oil-wells, but it is invariably synonymous with trouble of some kind or other, and always calls for the greatest skill and ingenuity on the part of the operators concerned. Technically speaking, the processes of side-tracking of tools, casing, or similar obstruction, frequently necessary in emergency, also come within the purview of "fishing jobs." The recovery of lost or "stuck" tools, runaway tools, broken ropes or rods, lost or broken casing, the removal of "frozen" pipe or other obstacle impeding the drilling of the well—these are some of the many kinds of trouble experienced by the driller. Fishing methods differ with the type of drilling system in vogue, with the efficiency of the drilling crew, and to a large extent according to the country in which the oil-field is situated. It should be borne in mind that operations of this character are usually lengthy, tedious, and expensive, since while they are being carried out the well certainly cannot be earning any money; consequently producers are becoming more and more alive to the necessity for reducing fishing operations to the absolute minimum, by the employment of the most skilful drillers, equipped with the most up-to-date tools and devices for achieving the desired results. Drilling is becoming more and more of a science, less of routine manual labour; it is therefore valuable to have the advantage of a paper such as Mr. Albert Millar's, read on November 13 before the Institute of Petroleum Technologists, dealing with the Galician-Canadian pole tool fishing methods, which provided a natural sequel to his previous paper on the same system of drilling for petroleum.

MERCURY AS A WORKING SUBSTANCE FOR BINARY FLUID TURBINES.—The possibilities of the use of mercury in this connexion were discussed in a paper read by Mr. William J. Kearton before the Institution of Mechanical Engineers on November 16. No fluid exists which possesses the ideal conditions for a single fluid turbine; hence the use of two fluids—one having a high boiling-point to be used in a high-temperature turbine, and the other with a low boiling-point to be used in a low-temperature turbine. Mercury may be used for the first fluid and steam for the second. It is stated that an experimental mercury-vapour turbine has been built in the United States by the General Electric Company to the designs of Mr. Emmett, and that a second turbine has recently been put into operation. There does not appear to be any published information on the subject in Great Britain. A considerable amount of experimental work has been done by chemists and physicists on the properties of mercury, but all the data required for a complete study of the problem are not at hand. A large amount of research work, particularly in connexion with the determination of latent heats at high temperatures, remains to be done. A considerable part of Mr. Kearton's paper is taken up with a discussion of the properties of mercury, and the results obtained by many workers are reviewed. The author has calculated tables giving the relation of temperature, vapour pressure, sensible heat, latent heat, total heat, entropies of the liquid, of evaporation, and of the mercury vapour; these tables appear in the paper, and are supplemented by diagrams showing the properties graphically.

The Royal Society Anniversary Meeting.

INSTITUTION OF RESEARCH PROFESSORSHIPS.

AT the anniversary meeting of the Royal Society held on November 30, the report of the Council was presented and the president, Sir Charles Sherrington, delivered his address. The report of the Council refers mainly to the chief benefactions made to the Society for the promotion of scientific investigation. These are the gift of 100,000*l*. made by Sir Alfred Yarrow in February last, a bequest of 50,000*l*. by Dr. Ludwig Mond, which came to the Society through the death of Mrs. Mond in May last, 500*l*. a year for at least five years from the Worshipful Company of Armourers and Brasiers, the Foulerton gift of 20,000*l*. and the bequest by Miss L. A. Foulerton of the residue of her estate, and the Messel bequest of four-fifths of the residuary estate. The income from the present investments of the four funds available for the endowment of scientific research is approximately as follows: Foulerton gift, 1000*l*.; Foulerton bequest, 4050*l*.; Messel fund, 1575*l*.; and Yarrow fund, 5450*l*. No income has so far been received from the Mond fund, but, according to the terms of the will, it is anticipated that there will be an annual income of about 2500*l*.

Upon the receipt of Sir Alfred Yarrow's gift, a committee was appointed by the Council to consider and make recommendations as to the general use and administration of the Foulerton, Messel, Yarrow, and Mond funds. Following a recommendation of this Committee, the Council resolved that in the first place the remaining sums of 250*l*. to be paid in respect of the yet unpublished volumes of the Royal Society Catalogue of Scientific Papers be paid out of the income of the Mond fund, and that after this the deficit of the Royal Society's publication fund should be met each year by contributions from the Messel fund and from the Mond fund, these contributions being made in so far as convenient in proportion to the total incomes of these two funds. It was further resolved on the recommendation of this Committee that the chief remaining part of the income from the various funds be used in the endowment of certain Royal Society professorships, these to be awarded to men only of proved ability for independent research; and regulations have been adopted both for the endowment of these professorships and for the endowment of scientific research in other ways out of the residue of the various funds. Detailed regulations for the administration of these four funds and for the appointment to and tenure of Royal Society research professorships have been adopted by the Council, and a separate Committee has been appointed to make recommendations as to the administration of the Yarrow fund.

Mr. G. I. Taylor, fellow and lecturer in mathematics, Trinity College, Cambridge.

YARROW RESEARCH PROFESSORS OF THE ROYAL SOCIETY.

Sir Charles Sherrington devoted his address almost entirely to an account of the institution of these research professorships and the policy adopted by the Society in regard to this means of securing the advancement of natural knowledge. It is felt that professorships endowed in the way described, so as to be mobile both as regards the University at which they are held and the subject of research, are of enormously greater value than professorships or fellowships tied for all time to a particular university and a particular subject.

The portions of the president's address referring to the use of these endowments, and to the work of this year's medallists, are printed below in a slightly abridged form.

SIR CHARLES SHERRINGTON'S PRESIDENTIAL ADDRESS.

At the anniversary meeting it cannot be out of place to iterate the main object of the Society's foundation—" the improvement of Natural Know-

ledge," by discovery, and as a never-failing means to that end, the furthering of research. A reference made to it at last year's anniversary dealt particularly with the funds at the disposal of the Society for assisting that great purpose. To-day, in reviewing, however briefly, the events of the past year, the Society recalls with lively gratitude the noble gift received from one of its fellows, Sir Alfred Yarrow. It is a gift specially directed towards this same essential aim of the Society's existence. The terms of Sir Alfred's letter accompanying the donation were no less generous and public-spirited than the gift itself. The letter stressed "that the money be used to aid scientific workers by adequate payment and by the supply of apparatus or other facilities, rather than to erect costly buildings."

The receipt of this splendid gift was followed at no long interval by the accruing to the Society of the valuable bequest from its past fellow, the late Dr. Ludwig Mond. The accession of these funds to the means at the Society's disposal for advancing research has enabled, and suggested, systemisation of its provision for that end. Consideration was undertaken of some adjusted scheme whereby the disbursements the Society could hope to make for the furthering of research should keep suitably in sight the whole ambit of the Society's purview of natural knowledge, thus making for advance over a wide scientific front. For such a plan the Foulerton, Messel, Yarrow and Mond funds, to mention them in their historical sequence, taken in conjunction and following the wishes of their individual donors, lend themselves well. The scope of destination of these funds extends from physics, chemistry, and engineering, on one hand, through biology, to, on the other hand, "Medicine and such sciences as are connected with the discovery of the causes of disease and the relief of human suffering." The mere scant enumeration of the circle of the natural sciences suffices to show them as a band of brothers, and seeing them as such is to remember their call is for research, and not even solely for science's sake itself, but for that of humanity as well.

In addition to the question of the breadth of field there remained that also of the particular form which help for research might take in order to be best effective in whatever field rendered. The consideration given to this has been very full and careful. It will be recalled that from the Donation fund and from some other funds of smaller amount, and also through the Committee administering the annual Government grant, the Society is able annually to make disbursements helpful for apparatus and material in response to applications in regard to particular items of research. Moreover, the Society has of research studentships five in addition to the Sorby fellowship. All and each of these have rendered and are rendering valuable aid to scientific research in their several respective ways. Broadly taken, their destination is to workers of promise in the earlier period of their career; and such workers are thus provided with opportunity for proving the powers of their promise. This year, in addition to the above, a generous and public-spirited step taken by the Worshipful Company of Armourers and Brasiers enables the Society to participate responsibly in the management of yet another endowment of somewhat similar scope.

Bearing in mind this relatively satisfactory provision already existent for these needs and recognising, further, the far-reaching outside provision available from Governmental and a number of public and private beneficiary sources, to meet requirements of a similar kind, the opinion arrived at after thorough consideration has been that a form of help specially called for, and specially likely to be effective in advancing discovery, would lie in the creation of greater opportunity for fully experienced investigators of already proven first-rate capacity in research. It is felt that increase of opportunity afforded to such investigators is likely to attain, with a prospect of comparative certainty, its recompense in the achievements such investigators will accomplish.

To open up facilities for this class of investigator would seem particularly the province of the Society, and one in which its help could pursue required directions with especially whole-hearted conviction, because the Society, in virtue of its own organisation, has special opportunity for cognisance of the powers and scientific circumstances of representatives of this class of investigator. Over an ample field, and at many points in that field, the Society lives in contact with their endeavours, conversant with work they have already done and often with work they are, in fact, prosecuting, and could prosecute more fully had they increased opportunity for so doing. The desirability for encouragement of research from the Society to take this kind of shape seems enhanced by circumstances of the present time, including as this present time does the likelihood of an immediate future which will be one of anxiety for finding ways and means. In institutions, university or other, for the most part such investigators occupy positions to which their opportunities for research attach rather as a secondary adjunct to calls of other nature upon their strength and time. Under an institution's financial stress the demand made by it upon members of its staff who have multifold duties other than research, is likely to be increased in directions away from research. This is a situation of hardship to the investigator and of detriment and mischance to the due advance of science itself.

Institutions, whether university or other, which are seats of learning, show themselves, in instance after instance, desirous for their personnel to prosecute research, but also, in instance after instance, embarrassed to secure to them adequate time for doing so. Yet the research activity of these men—or, for that matter, women—is a main source of that improvement of natural knowledge which it is the Society's great business to promote. A spring of indispensable supply for the production of new knowledge is thus stemmed or curtailed. Therefore, it is felt that the Society, by securing, in co-operation with this or that particular institution, ample freedom of time for a distinguished member of the personnel there to prosecute research undividedly, may extend a form of help toward the advance of discovery particularly desirable and welcome. It is felt that by so doing the Society can gear most usefully its own motive help into the general existent running machinery for the production of new scientific knowledge. The hope is, and the belief is, that its action may thus provide exactly a something which other institutions might have special difficulty in providing. The action it is taking marks a course which, although entered upon tentatively and to be judged finally by experience, is yet inaugurated with the foundation of three research professorships of the Society. The regulations for these appointments have been drawn up with intention to give the professors the utmost freedom to carry out research in the way dictated by their individual attainment, temperament, and inclination. The Council has not thought fit to insist that the professors either shall teach or shall not teach; the sole restriction laid down is that to research shall their main energies be devoted.

At the anniversary meeting last year I had the pleasure of referring to the appointment, then literally scarcely more than one hour old, of Prof. Starling as Foulerton professor. This year has seen him Harveian Orator of the Royal College of Physicians and, as regards the Society, entered fully upon the actual

activities of the Foulerton professorship. Now at this present anniversary, the pleasurable privilege falls to me of announcing the appointments of Prof. A. Fowler and Mr. G. I. Taylor to the Yarrow professorships. I may be allowed here a brief reference to their work. I follow the alphabetical order of their names. Prof. Fowler is known the world over as a spectroscopist whose researches have been of the greatest value to astronomy, to physics, and to chemistry. Entering on science first as a pupil of, and then as an assistant to, Sir Norman Lockyer, his earlier researches were, at that provenance made natural, astrophysical in kind, although the special technique which he developed was a technique of methods purely laboratory. He achieved extraordinary success in identifying lines observed in stellar spectra with lines which he was able to reproduce in the laboratory; he was able thus to assign the lines to their chemical origin. For example, the origin of the bands which dominated the spectra of what were then described as stars of Secchi's third class had been a mystery for many years. Fowler was able to show that they were due to titanium oxide. He accounted for many of the bands in the sun-spot spectrum by showing that they belonged to magnesium hydride. Again, he made an interesting study of the spectra of comets. The spectrum of the head had been observed by Donati in 1864 and had been fully studied by Huggins and others. It remained for Prof. Fowler to make a study of the tail spectrum of comets. He noticed first that the observed spectrum coincided with one which had been obtained in the laboratory arising from an impurity in low-pressure hydrogen. Finally, after much effort and laborious work, this spectrum was found to originate in carbon monoxide.

While these are perhaps some of the more striking of Prof. Fowler's successes in the region of astrophysics, he has also done a great deal of highly useful work in adding to our knowledge of the spectra of known terrestrial substances. Special mention may perhaps be made of his study of the spectrum of scandium, which proved to be important both in solar prominences and in sun-spots; of magnesium, in which he discovered new series of spectral lines; of strontium, in which he added several lines to the already known triple series; and of the active modification of nitrogen discovered by the present Lord Rayleigh.

At the time that these investigations were carried out, there was no reason to suppose an immediate future of practical importance for the results obtained, but with the advent of Bohr's theory of atomic structure, they have been found to provide exactly the material required for full discussion of the new theories of atomic structure, and for the acquisition of new positive knowledge as to the details of atomic mechanism. Perhaps his success of most striking general appeal has been his direct experimental proof that the so-called ζ-Puppis series of hydrogen originate from helium and not from hydrogen at all. This result incidentally provided a striking confirmation of Bohr's theory of the origin of spectra.

In this field of research Prof. Fowler stands unrivalled. Recently he has been examining the changes which take place in the spectra of elements as one electron after another is removed; the results obtained are of fundamental importance. His last paper, on the "Spectrum of Trebly Ionised Silicon," will still be fresh in the minds of many of our fellows.

Branches of physical science other than those benefiting by Prof. Fowler's work have formed the field of research of the Society's other Yarrow professor, Mr. G. I. Taylor, namely, mathematics, engineering, and geophysics. Mr. Taylor started his scientific life as an applied mathematician, and the Society is still fortunate in receiving from him frequent mathematical papers on hydrodynamical themes. Before the advent of Mr. Taylor to this field, it was almost a foregone conclusion that the results of mathematical research in a large part of hydrodynamics would not be confirmed by experiments; Mr. Taylor has opened an era in which experiments and analysis give confirmatory results. From abstract hydrodynamics he was led to research in practical problems of geophysics and meteorology. He has a distinguished record in aeronautical science, dating from the time when, acting as Meteorological Adviser to the Air Force, he was led to study the motions of the air, the causes and effects of eddies and the complicated phenomena to which these give rise. The application of much of his work to problems connected with aircraft is very direct. As the result of mathematical calculations he designed a parachute possessing many advantages in practice; quite recently he has published an important theoretical investigation as to the manner in which the forces on a model aeroplane in a wind-channel are affected by the eddies set up at the channel's mouth. Some contributions by him have proved of high value to the theory of the propeller. He has taken a leading part in the development of a theory which goes far to account for the forces of an aeroplane in terms of the circulation round it, and the series of trailing vortices shed from its wings.

Mr. Taylor has been equally successful in the application of mathematics to engineering problems. In collaboration with Mr. A. A. Griffiths, he was the first to utilise the fact that the equations which determine the torsion of an elastic bar are identical with those representing the displacement of a thin membrane stretched over a hole of suitable shape when slightly distorted by uniform pressure. By micrometric measurements of the distortion of such a membrane, he was able to deduce the torsion stresses inside a bar of specified cross-section, a procedure having practical applications of the greatest importance.

In the last Bakerian lecture delivered before the Society, Mr. Taylor, in conjunction with Miss Elam, studied the strains in a single crystal of aluminium when stretched to breaking point, using a most ingenious combination of micrometric measurements and X-ray analysis. In this way he was able to trace the internal motions in the crystal and to explain the striking difference between the fracture of a bar of ordinary metal and that of a single crystal, such as he examined. In this, his most recent work, he has opened up a field which promises to be of far-reaching importance to the science of the strength of materials, and, I venture to think, of great practical value to the working engineer.

The record of both of our new professors gives every justification for hoping that in the unfettered freedom of the Yarrow professorships they may find the opportunity for still more ample fulfilment of brilliant work. It is fortunate that they will both continue their researches in the laboratories from which their outstanding work has issued in the past, and of the traditions of which their reputations already are, indeed, a part.

Finally, may I in general terms return once more to summarise that leading motive, which has actuated the launching of these new professorships. Our universities and other scientific institutions have been wont—indeed in many cases by force of circumstances are compelled—to regard teaching as the primary occupation of professoriate and staff and to envisage their occupation by research as merely secondary to their occupation in routine teaching. The Society has inverted quite deliberately that

order of precedence of professorial function. By this inversion the Society of set purpose desires to recognise research as a definite profession and to advance, and to maintain, the principle that the labourer is worthy of his hire no less when engaged in research than when engaged in class instruction.

Yet one word more upon this subject. Munificent as the gifts are which the Society has received, enabling it to do what it is doing toward this end it has at heart, may we not venture to hope that the funds already to hand for that purpose will prove but the auspicious starting-point for yet others of similar destination. To say this is but to echo the concluding sentence of Sir Alfred Yarrow's memorable letter. With such aspirations, our desire is that in due course either the Royal Society or other bodies may have it in their power to endow the research of all those individuals whose life ought, in the best interests of the community, to be devoted to scientific research as the main purpose of their life-career.

THE MEDALLISTS.

COPLEY MEDAL. Prof. Horace Lamb.—For forty years Prof. Lamb has been recognised as one of the most prominent and successful workers in applied mathematics in Great Britain. He is the foremost authority on hydrodynamics, not only in Great Britain but the world over. Prof. Lamb's scientific activity, originally centring around the subject of hydrodynamics, has radiated thence into most branches of physical science and he may be regarded as the outstanding representative to-day of the school founded by Stokes, Kelvin, Clerk Maxwell, and Rayleigh. In recent years he has made important contributions to seismology, the theory of tides, and other branches of geophysics. Specially perhaps should be mentioned the assistance he has given of recent years to the Aeronautical Research Committee. Mathematical questions involved in the flow of air round aircraft, in the action of propellers, and the stresses in aeroplane structure, are of fundamental importance, but are exceedingly difficult; and here, as elsewhere, Prof. Lamb's mathematical skill and power of clear exposition have proved of the highest value.

ROYAL MEDAL. Prof. Charles James Martin.—Prof. Martin is distinguished for contributions both to physiology and to pathology. Investigating snake venoms, he differentiated two groups in virtue of their action, one nervous, the other, so to say, humoral. His work on heat-regulation in monotremes threw light on the evolution of the thermotaxis of warm-blood animals. More recently his researches have lain in the colloidal chemistry of proteins, and in protein-metabolism. As Director of the Lister Institute he has contributed to many investigations, in addition to those actually issued in his name. Thus he has been intimately associated with the inquiry into the influence of accessory food factors of diet in the prevention and remedying of "deficiency" diseases, such as scurvy and rickets, an inquiry the success of which may be regarded as one of the recent triumphs of preventive medicine.

ROYAL MEDAL. Sir William Napier Shaw.—In the great advances made during the last twenty-five years in the science of meteorology, Sir Napier Shaw has been amongst the foremost pioneers. During his twenty years' administration at the Meteorological Office, that Office saw three marked steps forward: two of these were changes in its quarters; the third and greatest was the change in outlook of the work of the Office, whereby it assumed, under Sir Napier Shaw's stimulating influence, the character of a scientific institution for the interpretation of meteorological phenomena. With the assistance of his scientific staff, he has developed the physical and dynamical aspects of the subject, and has done much to concentrate attention upon the thermodynamics of meteorology, wherein the motions of the water-laden air are interpreted as the action of a thermodynamic engine. His contributions to knowledge of the air and its ways have been largely responsible for changing the basis of meteorology from one of empiricism to one of science.

DAVY MEDAL. Prof. Herbert Brereton Baker.—Prof. Baker's researches in various fields of chemical investigation, his examination of highly purified tellurium from various sources for the possible presence of higher members of the same group of elements, and the redetermination of its atomic weight, are of outstanding merit. It is, however, his remarkable researches on the influence of traces of water in modifying chemical change, whether of the nature of combination or of decomposition, which constitute perhaps his especial distinction. The results obtained by complete drying were as remarkable as they were unexpected, because they were in direct opposition to those which followed careful drying by usual methods. The bearing of Prof. Baker's researches on theories of chemical change is as important as his conclusive experimental demonstrations of the phenomena themselves.

HUGHES MEDAL. Dr. Robert Andrews Millikan.—Dr. Millikan has long been regarded as one of the most skilful experimenters in physical science. He is awarded the Hughes medal especially for his determinations of the electronic charge e and of Planck's constant h. When physicists were still ignorant of the value of the electronic charge to within 5 per cent., Dr. Millikan, by a method of the utmost ingenuity, arrived at the value $4{\cdot}774 \times 10^{-10}$ E.S.U., for which he claimed an accuracy of one part in a thousand, a claim which has stood the test of time. His determination of h was not only remarkable in itself, but was of still greater value as finally vindicating the Einstein-Bohr view of the nature of the photo-electric phenomenon.

University and Educational Intelligence.

EDINBURGH.—Dr. Theobald Smith, of the Rockefeller Institute for Medical Research, New York, United States, gave an address in the University on Tuesday, November 27, on comparative pathology. He emphasised the common basis—theoretical and biological—of human and animal pathology; the divergence in methods of treatment of human and of animal patients is determined in the case of the latter by economic considerations. He urged that individual treatment of animals should be replaced more and more by preventive measures, and that future stock-owners should be brought to realise this by a sound education in the principles underlying disease.

LIVERPOOL.—Sir Heath Harrison, Bart., founder of the chair of organic chemistry in the University, has generously contributed a further sum of 2500*l.* towards the endowment of the chair.

DR. C. E. WEATHERBURN, of Ormond College, Melbourne, has been appointed professor of mathematics at Canterbury University College, Christchurch, New Zealand.

The Annual General Meeting of the Association of Women Science Teachers will be held on Saturday, January 26, at University College, London. In the afternoon Miss Elles will lecture on "The Scientific Interpretation of Scenery" and the meeting will be open to all who are interested in the subject.

In London, Ontario, the corner stones of the new arts and science buildings of the University of Western Ontario (formerly known as the Western University of London) were laid on June 18 last by the Premier of the Province. The cost of the buildings, more than a million dollars, is being provided for chiefly by grants from the provincial and county governments. The University has grown rapidly in recent years, its student enrolment (610) being three times as large as before the War.

A professor of botany and director of the biological laboratories in the University College, Colombo, Ceylon, is required. Candidates should hold a first-class honours degree of a British University, with botany as the principal subject, or equivalent qualifications, and have a competent knowledge of plant physiology, with an acquaintance of botany as applied to agriculture either as plant pathology or genetics, or soil biology. Further information of, and application forms for, the appointment are obtainable until December 15, from the Assistant Private Secretary (Appointments), Colonial Office, Downing Street, S.W.1. The completed application forms must be returned by January 1.

Among "significant movements in city school systems" described in Bulletin No. 8 of 1923 of the United States Bureau of Education is the increase in size of the school buildings and grounds. In the larger cities buildings with 24 or more rooms are beginning to appear. This movement is partly due to the insistent modern demand for adequate provision in connexion with city schools for recreation, for physical training, and for practical work. In many cities it has been found that the expense involved in providing for these activities the requisite gymnasiums, auditoriums, manual training shops, home-economics and science laboratories, drawing and modelling studios, and playgrounds, while maintaining class rooms on the same scale as before for ordinary class instruction, is prohibitive. The "platoon," or "work-study-play," or "duplicate school" plan divides the school children of all grades into two groups—A and B. While those of group A are in the class rooms those of group B are in the playgrounds, auditorium, laboratories, or other specially equipped rooms, and vice versa, so that the school can be run with half the number of class rooms required under the ordinary system. Such schemes have been introduced in 53 cities, and in one of these more than 50 "platoon" schools are established.

The Cincinnati public-schools psychological laboratory is responsible for an interesting attempt to trace the causes of failure in first and second-grade work of children not classified as mentally deficient. The experiment was carried out in an "observation class" of sixteen children from 1917 to 1921, and a detailed account of it has just been published in "Diagnosis and Treatment of Young School Failures"—Bulletin No. 1 of 1923, of the Washington Bureau. Diagnosis should, the writer declares, take account of the child's mental level (as indicated by the various intelligence tests), school history, state of health, general mental tone and attitude (*e.g.*, obsessions, phobias, or anxiety-states), and heredity. Treatment in the observation class resulted uniformly in improvement as measured by mental tests notwithstanding that operative correction of physical defects such as removal of diseased tonsils and adenoids was, owing to parents' objections, in no case effected and unfavourable home conditions remained unchanged. Pleading for a widely extended development of psychological and medical clinics and other extra-class-room resources, the writer remarks, "The community-wide contacts of the school and its hold on the family through the child give it a strategic position for the discovery and diagnosis of mental, physical, and social ills which no other agency can possibly equal."

The annual meetings of the Geographical Association will be held in Birkbeck College, London, on Wednesday, Thursday, and Friday, January 2, 3, and 4, 1924. The programme includes the following items:—Jan. 2, Prof. P. M. Roxby will open a discussion on "Regional Study in the University and the publication of its results"; Jan. 3, Mr. L. Mac D. Robison will give an address on Ceylon; Sir Richard Gregory will give his presidential address on "British Climate in Historic Times"; joint conference between the Royal Meteorological Society, the Geographical Association, and the Science Masters' Association, to consider the place of meteorology in education. Sir Napier Shaw will preside. Subjects of discussion: "The Place of Meteorological Observations in the School Course," and "The Teaching of Meteorology and Climatology in Schools from (1) the physical and (2) the geographical standpoint"; and M. Em. de Martonne, professor of geography in the University, Paris, will speak (in English) on "A Study of Transylvania"; Jan. 4, conference on railway geography. Mr. Alexander Bell, Assistant General Manager, L. and N.E. Railway, in the chair. Opened on behalf of the Geographical Association by Mr. Ll. Rodwell Jones and Mr. C. B. Fawcett.

In 1919, arising out of a suggestion put forward by the Universities Bureau of the British Empire as to the desirability of establishing a scheme for the interchange of students between the Universities of Great Britain and America, the Imperial College of Science and Technology, S. Kensington, with the generous assistance of two of its governors, Sir Arthur Acland and Sir Otto Beit, initiated as an experiment a project designed to afford to selected Imperial College students a year's post-graduate study either at an American university, or in American works. The hope of the founders was that the awards might not only prove mutually advantageous to the students of the two countries, but also that a closer acquaintance would tend to foster a spirit of good fellowship and mutual understanding between the students of the two countries and the countries themselves. The original scheme contemplated 6 scholarships of 300*l*. each for one year, which the Imperial College made 400*l*. a year, and later Sir Alfred Yarrow generously contributed a sum sufficient to provide 4 additional scholarships. In all 12 scholars were sent to America, 10 with, and 2 without emoluments; 6 of these went to the Massachusetts Institute of Technology, 2 to Columbia University, 1 each to Cornell, Harvard, and Yale Universities, and 1 spent the year with the Tennessee Iron Coal and Railroad Co., and other works. Five of the scholars were awarded the degree of master of science at the conclusion of the year, and arrangements were made in three cases by the American institution for the students to remain for a second year. Judging from the reports which have been received, the experiment has been an undoubted success. The awards have been discontinued as the funds have been exhausted.

Societies and Academies.

LONDON.

Royal Anthropological Institute, November 6.—Prof. C. G. Seligman, president, in the chair.—Miss M. A. **Murray**: The Percy Sladen Memorial Fund Excavations at Borg en Nadur, Malta. The apsidal building found last year was completely excavated, and further excavations were carried on to the east and south. The main entrance to the megalithic enclosure was cleared; on each side of the gateway was a tall megalith, and just within the enclosure on each side was a small chamber built of megalithic blocks. In an angle of each of these chambers a pot of the Bronze-age was found, evidently in position. The enclosure wall curves away from the main entrance towards the south and west; but there was not time to clear this completely. The outer blocks of the apsidal building were laid bare; they occur only round the west end and the north-west apse. Originally, they were probably six feet or more in height; now, however, they are about three feet high, as the tops have been broken off to bring them to the level of the field. Numbers of small flint implements were found in all parts of the site, chiefly in and near the apsidal building. To the west of the apsidal building the so-called "Neolithic stratum" was clearly marked, the earth being of a different colour from that above and below, and Neolithic potsherds occurring in large numbers. As this part of the excavation was at the boundary of the next field, it was not possible to continue the excavation further in that direction. It is hoped that the Maltese Government will buy the fields which contain the megalithic structures, and thus ensure that all the buildings of Borg en Nadur may be completely excavated.

November 20.—Prof. C. G. Seligman, president, in the chair. L. H. **Dudley Buxton**: The inhabitants of Inner Mongolia. The inhabitants of Inner Mongolia may be divided into three classes—Mongols, Chinese, and Manchus. The Mongols only are discussed: they are usually divided into three groups—the Kalmucks, the Buriats, and the true Mongols. This classification is based on linguistic relations alone. The majority of the true Mongols have adopted the Lamaistic form of Buddhism, but a number of relics of Shamanism survive, some of the rites being strongly reminiscent of Arctic hysteria. All their rites and ceremonies are in close harmony with their geographic environment, and are closely related to their occupations as pastoral nomads. Their physique differs from that of the Kalmucks and from many of the Buriat tribes. They seem to stand intermediate between the Turkish tribes of Central Asia, such as the Turguts and the Taranchi, and the Northern Chinese, although in many ways they are nearer the latter. They probably received a considerable infiltration of Western blood, perhaps akin to that of the Alpine race, possibly at a time which was contemporaneous with the culture represented in Fengtien by the Sha Kuo T'un pottery, although the actual people who occupied this site seem to have been early Chinese. If we regroup the Mongols on the basis of physique, most of the Kalmucks and many of the Buriats fall in a class akin to many of the Turki tribes, and distinguished for their extremely round heads, and to form a separate class which will include probably most of the true Mongols and the Buriats and possibly some of the Kalmucks. These are closely allied to the yellow races, although they, too, probably have a strain of white blood in their veins.

Physical Society, November 9.—Dr. Alexander Russell in the chair.—A. L. **Narayan**: Scattering of light by carbon dioxide, nitrous oxide, and some organic vapours. The light scattered laterally by the molecules of gases is not completely polarised, but contains a component polarised at right angles to the direction which is predicted by theory for a spherical molecule, the two components being conveniently referred to as the "wrong" and the "right" components respectively. Sunlight was used for illuminating gases and vapours, enclosed in a jointless tube. The strengths of the components were compared both by direct photometry and by photometric comparison of their effects on a photographic plate. Lord Rayleigh's results were confirmed, particularly in the case of carbon dioxide and nitric oxide. The difference in the scattering power of these two gases is contrary to the prediction of the Lewis-Langmuir theory of the atom.—A. **Ferguson**: On the measurement of the surface tension of a small quantity of liquid. If a small quantity of liquid, 1 c.c. or less, be placed in a vertical capillary tube, its surface tension may be determined by applying pressure to the upper end of the tube, and measuring the pressure necessary to force the liquid into such a position that the meniscus at the lower end of the tube is *plane*. Interfacial tensions may also be determined in this way.

The Faraday Society, November 12.—Sir Robert Robertson, president, in the chair.—A. J. **Allmand** and A. W. **Campbell**: The electrodeposition of manganese. The electrodeposition of manganese from aqueous solutions of its sulphate and chloride has been studied, and the effects of changes in composition of electrolyte, current density, temperature, and type of cell investigated. Pure manganese in coherent form can be prepared in small quantity with a current efficiency of 40-50 per cent., but attempts to prepare larger amounts in coherent form were unsuccessful.—S. **Glasstone**: The cathodic behaviour of alloys. Pt. I. Iron-nickel alloys.—A. L. **Norbury**: The volumes occupied by the solute atoms in certain metallic solid solutions, and their consequent hardening effects. When an element is distributed in solid solution as single atoms replacing single atoms of the solvent in the space-lattice of the latter, the hardening effect is, in general, proportional to the difference in size of the solute and solvent atoms. This relationship does not hold in certain exceptional cases—for example, silicon in copper and sodium in lead, which appear to arise when the solute has an exceptionally strong chemical affinity for the solvent. In such cases the solute probably exists in solid solution in the form of molecules of an intermetallic compound having a different space-lattice from that of the solvent. When an element forms a solid solution with another element, there is a contraction or expansion which seems to be large or small according to whether the chemical affinity between the elements is large or small.—J. B. **Firth** and F. S. **Watson**: The catalytic decomposition of hydrogen peroxide solution by blood charcoal. Blood charcoal previously heated to 120° C. shows moderate catalytic activity in the decomposition of hydrogen peroxide solution, but the activity is considerably increased by previous heating in a vacuum at 600° C. and 900° C., and is still further increased by previous sorption of iodine from solution. The activity of an activated charcoal consists of two types: α activity, which is very rapid, but ceases after a few minutes, and β activity, which may persist for several hours. In ordinary blood charcoal α activity is absent. The introduction of iron into sugar solution prior to carbonisation increases the

activity of the charcoal considerably, and it is suggested that the iron acts as a spacing agent. The proportion of hydrogen peroxide decomposed is determined by *both* the activity of the charcoal and the concentration of the solution.—E. E. **Walker**: The influence of the velocity of compression on the apparent compressibility of powders. The influence of the duration of the load on the volume ratio of compressed powder has been investigated, and the isobaric curve has been correlated with the value of the ratio resistance to impact to resistance to static load. The exceptional readiness with which powdered ammonium nitrate shrinks depends chiefly on the high value of its velocity coefficient.—L. **Anderson**: (1) An investigation of Smoluchowski's equation as applied to the coagulation of gold hydrosol. Colorimetric determinations of the rate of coagulation of gold sols by hydrochloric acid, potassium chloride, barium chloride, and aluminium chloride have been carried out, and a region of rapid coagulation is found in which Smoluchowski's equation holds fairly well. A slower region of coagulation is found in which the equation is inapplicable. On the whole, the equation in its present form is strictly limited to rapid coagulation. (2) The effect of sucrose on the rate of coagulation of a colloid by an electrolyte. The coagulation of gold sols by hydrochloric acid, barium chloride, and potassium chloride in the presence of varying amounts of sucrose has been investigated. It is concluded that sucrose exerts a definite peptising effect upon colloidal gold, and also that it exerts a specific augmentation of coagulation in the case of hydrogen and barium ions over and above that of increasing the activity of these two ions. It exhibits apparent antagonistic action towards ions and gold sols. The experiments indicate in general that the coagulating power of an ion is dependent upon its activity rather than upon its concentration, a conclusion which brings the typical colloid phenomenon of coagulation into line with the kinetics of chemical change in homogeneous (molecular) systems.—H. H. **Paine** and G. T. R. **Evans**: A method of measuring the rate of coagulation of colloidal solutions over wide ranges. The rate of coagulation of colloidal copper solutions has been studied for a wide range of electrolyte concentrations by making use of the retarding effect of starch. Very rapid coagulations can thus be brought into the region of observation by ordinary methods. A "transformation factor" can be obtained which enables one to calculate what the rate of coagulation would have been for the pure colloid. The results agree closely with the equation deduced by Freundlich for the variation of the rate of coagulation with the concentration of the electrolyte, and confirm the existence of a maximum rate of coagulation.—J. A. V. **Butler**: Studies in heterogeneous equilibria. Pt. I. The conditions at the boundary surfaces of crystals and liquids are discussed with the view of applying statistical methods to elucidate the kinetics of surface processes and to co-ordinate a number of different cases of heterogeneous equilibrium. A molecule near the surface is under the influence of two opposing attractive forces, that of the surface and that exerted by the liquid. In general, these result in a balance point at which the direction of the resultant force reverses. Suitable approximate statistical equations are deduced on this basis and applied to the simplest cases of solubility. The integration constants of the isochore for solubility calculated by means of the equations obtained for potassium, sodium, hydrogen, and silver chlorides, are of the same order of magnitude as the experimental values.

Royal Statistical Society, November 20.—Sir J. **Athelstane Baines**: The International Statistical Institute and its fifteenth session. The International Statistical Institute originated at the jubilee meeting of the Royal Statistical Society. During the War, its work was in abeyance, with the exception of that carried on by the Permanent Office, which had been established only a short time before hostilities began. The Institute was able to convene its fifteenth session to take place at Brussels last October. At the request of the League of Nations, through the Economic Section, proposals for the organisation of statistics for international comparisons were submitted to the Institute, and forwarded, as adopted, to the League. The subjects dealt with were statistics of trade, of agricultural production, and of fisheries, together with suggestions as to the use and form of index-numbers bearing on the economic situation. It is possible that the counsel of the Institute may be sought by the League systematically as time goes on, since the need of a qualified adviser, independent and impartial, upon international questions involving a statistical basis, is becoming annually more apparent.

PARIS.

Academy of Sciences, November 12.—M. Albin Haller in the chair.—J. **Costantin**: The collection and culture of *Pleurotus Eryngii*. Suggestions for the cultivation of this edible mushroom (and other species of Pleurotus) on waste land.—H. A. **Lorentz** and Edouard **Herzen**: The relations between energy and mass according to Ernest Solvay.—E. O. **Lovett**: A functional property of certain surfaces.—Armand **Cahen**: New continued fractions attached to certain operations.—Serge **Bernstein**: Quasi-analytical functions.—Jean **Chazy**: The gravitation field of two fixed masses in the theory of relativity.—Carl A. **Garabedian**: A method of series.—Charles **Nordmann**: The "turbulence" of the wind and the flight of hovering birds. Discussion and criticism of the views of Vasilesco Karpen on this subject.—Emile **Belot**: Some consequences of the fact that all stars, including the sun, must have passed through the nova phase.—J. **Rouch**: Researches on shoals with the aid of the divergent drag. This instrument, invented by Admiral Ronarch during the War for removing submarine mines, has been successfully applied to the detection of submerged rocks in the neighbourhood of the port of Brest.—René **Lucas**: Magnetic moments of rotation and molecular magnetic orientation.—R. **Ledoux-Lebard**, A. **Lepape**, and A. **Dauvillier**: The use of heavy gases in radio-diagnosis. Radiographs of a frog, before and after breathing krypton, show that this gas is as opaque to X-rays as the tissues of the animal.—Léon **Guillet**: The electrical resistance of commercial aluminium. The purest commercial aluminium has a specific resistance of 2·8 micro-ohms, and this increases with the amount of impurities. Silicon appears to cause a greater increase of resistance than iron. Mechanical treatment has only a slight effect on the resistance.—W. **Kuhn**: The decomposition of ammonia by ultraviolet light and the law of photo-chemical equivalence. The number of quanta absorbed per molecule of ammonia is between 2 and 2·5: this number is increased as the light is made more nearly monochromatic and is independent of the pressure and, in the interval 10° and 20°, of the temperature.—Pierre **Bedos**: Ortho-cyclohexyl-cyclohexanol. This is prepared, with good yield, by the interaction of cyclohexene oxide and cyclohexyl magnesium chloride. Only one of the two possible stereoisomers is obtained: other methods of preparation of this alcohol have given a mixture of the two isomers.—

P. **Gaubert**: The determination of minerals by the microscopical examination of the streak left on a hard body. The microscopical examination of the streak produced on a plate of ground glass or quartz can be used as a means of rapid identification of a mineral or of its constituents. It has the advantage of using only a minute weight of the material without damage to the specimen.—Sabra **Stefanescu**: The activity and correlation of the molars and maxillaries of mastodons and elephants.—René **Souèges**: The embryogeny of the Plantagaceæ. The development of the embryo in *Plantago lanceolata*.—J. **Dauvergne** and Mlle. L. **Weil**: A method of propagating by cuttings in a sterile liquid medium.—J. **Beauverie**: The yellow rust of wheat (*Puccinia glumarum*) in 1923.—Henri **Coupin**: The swelling of seeds and the osmotic pressure of the medium. From experiments on the swelling of seeds in sugar solutions of varying concentration it is shown that the osmotic pressure of the cells of seeds is generally high, from 20 to 45 atmospheres.—H. **Colin** and H. **Belval**: The levulosanes in cereals.—Ph. **Joyet-Lavergne**: The cytoplasmic structure of *Adelina dimidiata*, a parasite of *Scolopendra cingulata*.—Pierre **Danglard**: The vital coloration of the vacuolar apparatus in the marine peridians.—Jules **Amar**: Transformism and heredity.—L. **Fage** and R. **Legendre**: The lunar rhythms of some nereidians.—C. **Levaditi**, S. **Wicolau** and Mlle. R. **Schoen**: Etiology of encephalitis.

Livingstone College. Annual Report and Statement of Accounts for the Year 1922-23. Pp. 24. (Leyton, E.10.)

The Manchester Steam Users' Association for the Prevention of Steam Boiler Explosions, and for the Attainment of Economy in the Application of Steam. Memorandum by Chief Engineer for the Year 1922. Pp. 23. (Manchester.)

Diary of Societies.

MONDAY, DECEMBER 10.

VICTORIA INSTITUTE, at 4.30.—W. Dale: Egypt in the Days of Akhenaten and Tutankhamen.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—Dr. A. T. Doodson: The Work of the Liverpool Tidal Institute.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (Annual General Meeting) (at London Day Training College), at 5.30.—Prof. Wynn-Jones: Vocational Tests in Music.

SOCIETY OF ENGINEERS, INC., at 6.—Annual General Meeting.

ROYAL SOCIETY OF ARTS, at 8.—Prof. A. F. Barker: Recent Progress in the Wool Industries (Cantor Lectures) (2).

TUESDAY, DECEMBER 11.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—L. R. McCollum: The Modern Rotary Drilling System.

INSTITUTE OF TRANSPORT (Metropolitan Graduate and Student Society) (at Institution of Electrical Engineers), at 6.—C. Anderson: Ministry of Transport Requirements, with reference to Railway Companies.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—Adjourned Discussion on Paper read by E. W. Blocksidge at the Shipping and Engineering Exhibition on Life Saving Appliances on Large Passenger Steamers.

ROYAL PHOTOGRAPHIC SOCIETY (Scientific and Technical Group), at 7.—W. Clark: The Sensitivity of the Silver Halide Grains of a Photographic Emulsion.—Communications from the Eastman Kodak Research Laboratory.—L. A. Jones and E. Huse: The Relation between Time and Intensity in Photographic Exposure.—J. B. Capstaff and N. B. Green: A Motion Picture Densitometer.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—J. E. Barnard: Some Problems in Medical Microscopy.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—G. Herbert, R. A. Ives, and others: Discussion on Some Applications of Illuminating Engineering in Practice.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—G. Hewett: The Dusun of British North Borneo.

WEDNESDAY, DECEMBER 12.

INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 7.—W. P. F. Fanghaenal, W. N. Booth, and others: Discussion on The Lighting of Factories.

ROYAL SOCIETY OF ARTS, at 8.—Sir Frank Baines: The Preservation of Historic Buildings and Ancient Monuments.

ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. W. L. Templeton and Dr. H. J. Macbride: The Malaria Treatment of G.P.I.

THURSDAY, DECEMBER 13.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—H. B. C. Darling: The Trinomial Quintic.—H. D. Kloosterman: Representation of a Number in the Form $ax^2+by^2+cz^2+dt^2$.—Prof. Tadahiko Kubota: Some Inequalities concerning Ovals and Ovaloids.—W. L. Marr: The Occurrence of a Linear Determinantal System of Points.—Major P. A. MacMahon: Properties of Prime Numbers deduced from the Calculus of Symmetric Functions.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Miss Kate Stevens: My Trip round the World.

INSTITUTION OF ELECTRICAL ENGINEERS at 6.—D. Brownlie: Pulverised Fuel and Efficient Steam Generation.

SOCIETY OF DYERS AND COLOURISTS (London Section) (at the Dyers' Hall, Dowgate Hill), at 7.—A. E. Woodhead: Colour Solvents and their Application to Textile Fibres.

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—T. Smith: The Primary and Secondary Constant Magnification Surfaces of Thin Lenses.—W. Swaine: A Suggested Standard Trial Case and Simplification in Ophthalmic Policy.—B. K. Johnson: Exhibition of an Optical Revolution Counter.—D. Baxandall: Exhibition of the Troughton Dividing Engine (from the Science Museum, Kensington).

C.B.C. SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS (at Essex Hall), at 8.—Prof. E. W. MacBride: The Inheritance of Mental Defects.

INSTITUTE OF METALS (London Local Section) and INSTITUTION OF BRITISH FOUNDRYMEN (at Institute of Marine Engineers, Inc.), at 8.—A. H. Munday: Some Foundry Problems.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (Laboratory Meeting) (at London School of Tropical Medicine, Endsleigh Gardens), at 8.15.

FRIDAY, DECEMBER 14.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Dr. J. H. Jeans: Internal Motions in Spiral Nebulæ.—J. W. Gifford: Telescopic Triple Object Glass of High Relative Aperture.—J. S. Plaskett: The H and K Lines of Calcium in O-type Stars.—J. H. Reynolds: The Galactic Distribution of the Small Spiral and Spheroidal Nebulæ.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Prof. A. H. Gibson and H. W. Baker: Exhaust-Valve and Cylinder-Head Temperatures in High-speed Petrol Engines.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—S. Bylander: L.C.C. Regulations for Steel Framed Buildings.

SATURDAY, DECEMBER 15.

BRITISH PSYCHOLOGICAL SOCIETY (Annual General Meeting) (at University College), at 3.15.—Miss H. M. Wells: A Note on the Psychological Significance of the Psycho-galvanic Reaction.—J. Kay: Visual Perceptual Tests.

PUBLIC LECTURES.

SATURDAY, DECEMBER 8.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. E. M. Delf: Sunlight and Life.

MONDAY, DECEMBER 10.

UNIVERSITY COLLEGE, at 5.30.—Prof. J. N. Bronsted: Some Chapters in the Recent Development of the Theory of Electrolytic Dissociation. (Succeeding Lectures on December 12 and 14.)

TUESDAY, DECEMBER 11.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4.—F. W. Twort: The Influence of Environment on the Life of Bacteria. (Succeeding Lectures on December 13, 17, 18, and 19.)

ROYAL INSTITUTE OF PUBLIC HEALTH, at 5.—Prof. D. Levaditi: Harben Lectures. (Succeeding Lectures on December 12 and 13.)

KING'S COLLEGE, at 5.30.—Miss Hilda D. Oakeley: The Roots of Early Greek Philosophy: Ethical.

WEDNESDAY, DECEMBER 12.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—H. D. Herring: The Disposal of the Dead, with Special Reference to Cremation.

WESTFIELD COLLEGE (Hampstead), at 5.15.—Prof. Craigie: The Making of a Dictionary.

THURSDAY, DECEMBER 13.

KING'S COLLEGE, at 5.30.—Prof. Seton Watson: The Balkan States and Europe (League of Nations Union Lecture).

UNIVERSITY COLLEGE, at 5.30.—Miss M. A. Murray: Matrilineal Descent.

SATURDAY, DECEMBER 15.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: My Excavations in Malta.

SATURDAY, DECEMBER 15, 1923.

The Problems of Pasteurisation.

IN the recent National Milk Conference convened by the National Clean Milk Society at the Guildhall, London, the problems of pasteurisation which formed the subject of articles in NATURE for January 27 and February 3 of this year were discussed. Pending the publication of fuller reports, it would appear that not much additional knowledge has been acquired from experimental or other investigations since those articles appeared. Opinion in the Conference differed widely as to the wisdom of pasteurisation of cows' milk under present conditions. Thus, Prof. H. E. Armstrong maintained that the Ministry of Agriculture and the Ministry of Health were working against the public interest by "patting pasteurisation on the back," while not forcing those who heated milk to tell the public what they had done with it. With the emphasis laid in this statement on the desirability of making it compulsory to declare the fact of pasteurisation and the temperature at which it is undertaken, when commercially practised, all hygienists will agree; but they would scarcely agree with the possible inference that regulated pasteurisation of milk is an evil. Other hygienists, like Profs. J. M. Beattie and H. R. Kenwood, favoured the practice of pasteurisation, the first named summarising his views in the words that pasteurisation, properly carried out, at a constant temperature somewhat higher than that at present in use, would bring about the destruction not only of tubercle bacilli but also of all other important pathogenic organisms.

The problem of pure milk is complicated by the desirability of cheap milk, and of increase in the per capita consumption of milk from about a quarter of a pint daily to at least three times this amount. Clean milk is necessarily expensive. The dangers from relatively uncleanly milk are reduced to a minimum by efficient pasteurisation. At the same time, improved sanitation of milk is extremely important even when pasteurisation is contemplated; while conversely, even clean milk produced under rigid conditions may occasionally cause disease unless it is pasteurised.

Neither method of approach to improvement can be neglected. Dairy and milk sanitation is important; but, for the efficient protection of the masses of population living in large cities, pasteurisation is necessary. This pasteurisation must, however, be efficient, and to be efficient it must be controlled and always declared, in order that the circumstances in which pasteurisation has been carried out may be inspected. Furthermore, more experimental work is needed on the various processes of pasteurisation as to their relative efficiency.

Facts and Fancies in Modern Anthropology.

(1) *The Evolution and Progress of Mankind.* By Prof. H. Klaatsch. Edited and Enlarged by Prof. A. Heilborn. Translated by J. McCabe. Pp. 316. (London: T. Fisher Unwin, Ltd., 1923.) 25*s*. net.

(2) *The Racial History of Man.* By Prof. R. B. Dixon. Pp. xvi+583+44 plates. (New York and London: Charles Scribner's Sons, 1923.) 25*s*. net.

(3) *Ancient Man in Britain.* By D. A. Mackenzie. Pp. xv+257+16 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1922.) 12*s*. 6*d*. net.

THE three anthropologists the titles of whose works are given above have approached problems relating to the origin of human races and of their civilisations by totally different routes, but all of them have this in common: they have reached their respective destinations by giving their imaginations the freest of reins. No one who examines the frontispiece of the late Prof. Hermann Klaatsch's book—his death in 1916 at the age of fifty-two robbed German science of one of its boldest exponents—would readily associate his burly body and prize-ring face with fanciful speculations regarding man's evolution. Nor do we expect Prof. Roland B. Dixon, who holds the chair of anthropology at Harvard University, to use a few measurements of the skull as fairy wands wherewith to rear wonderful anthropological castles in the air of long past ages. His castles, we fear, like those which children build on the sands, are doomed to disappear as the incoming tide of reason flows over them—but of this, more anon. There can be no doubt that Dr. Donald A. Mackenzie's imagination is a part of himself; he is a student of Celtic literature, of Egyptian mythology, of primitive folk-lore. He has that invaluable quality, denied to men of strictly scientific training, of entering the primitive human mind, seeing the world through its eyes, and understanding its modes of reasoning. He has used his gifts and training in drawing a word-picture of ancient man in Britain and the sort of life he lived.

(1) Prof. Klaatsch's book, finished and edited by his friend, Prof. A. Heilborn, and translated into English by Mr. Joseph McCabe, contains a popular account of the opinions he had formed relating to the origin of man and his mind; to the beginnings of his speech, his morals, his weapons, his home, and his societies. However much one may resent the brusque way in which this German professor has brushed aside the facts and opinions of most of his contemporaries, and the dogmatic way in which he has made assertion serve the place of reason, yet his writings demand and deserve our serious consideration. Klaatsch was trained under Gegenbaur and became his assistant. He had been assistant to Waldeyer, and from his boyhood had been a close student of Darwin and of Huxley. He came into European prominence towards the end of last century, when the late Prof. Schwalbe of Strasbourg was giving Neanderthal man the place originally assigned to him by Dr. William King—that of a quite distinct species of humanity, sharply marked off from all living varieties of mankind.

Klaatsch made the fossil remains of man—particularly of Neanderthal man—his special study, and published long and somewhat prolix monographs on them. Then he took up the study of ancient stone implements, and proceeded to sites in Belgium and England to learn at first hand their nature and antiquity. To help him to interpret the ways of ancient man in Europe he set out in 1904 to live in contact with the most primitive of living races—the aborigines of Australia. He never ceased to extol the fine gentlemanly qualities of the aboriginal Australian; he persuaded himself that he detected Indo-Germanic elements in the aborigines' speech, and took a particular delight in claiming the Australian native as the ancestral type of the European! Much of the book here reviewed is based on experience he gained during the three years spent in Australia. He returned in 1907 to fill the full chair of anatomy and anthropology in the University of Breslau, and to rush about the continent of Europe to see the latest find of fossil man. He was soon in the sand-pit of Mauer when the Heidelberg jaw was found; he was in the Dordogne when his Swiss friend, Hauser, uncovered fossil remains of man at Le Moustier and at Combe Capelle; he went to Agram to see the remains discovered at Krapina. With such a record we cannot turn down lightly the opinions of this robust and industrious German professor.

Prof. Klaatsch was a vigorous exponent of evolution, but as regards the origin of human races he held certain peculiar opinions, to which he first gave expression after making a detailed examination of the fossil remains of Neanderthal man. He found that this extinct species of mankind shared many minor characters with the gorilla, and to account for the common heritage he framed the conception that they were co-descendants from an ancestral stock of ape-men. For reasons which he never made quite clear, he linked the Negro race on to the Gorilla-Neanderthal stem. He further supposed, without a scrap of evidence, that these ancestral ape-men were in our modern sense more man-like than ape-like, and while the gorilla fell away towards apedom as evolution went on, his more fortunate cousins—the Negro and Neanderthal man—proceeded towards their higher goals. He returned to the discarded idea of

Lord Monboddo, that apes were degenerate men—or, to use Klaatsch's own expression, they represent "abortive attempts at human evolution." On the other hand, the races of Europe, Asia, and Australia, although they, too, had arisen from the same ancestral stock of ape-men, had taken a totally different route to reach their humanity, having been accompanied in part of their evolutionary journey by the ancestry of the orang—another abortive attempt at man-production. Klaatsch himself was uncertain as to which human race had its past twined with the ancestry of the chimpanzee, but some of his followers have provided its human counterpart and also one for the gibbon. Once one enters the topsy-turvy evolutionary mill of the polygenist, there is no calling a halt: the extinct forms of anthropoid apes will also require human counterparts if Klaatsch's views are sound; and as geologists will provide scores of them in the course of time, the fertile imagination of the polygenist must look forward to a busy and perplexing future.

What should we say if any one were solemnly to assure us that Spanish and Italian were speeches of diverse origin, but that as they evolved they had come to resemble each other? Those who maintain that the close structural resemblances between the Negro and the European are due to convergence, as Klaatsch did, take up an equally untenable position.[1]

It must not be thought that the whole of Prof. Klaatsch's book is given over to a discussion of the evolution of man's body and brain. Far from it: a chapter is devoted to the evolution of weapons and to the discovery of fire and the results which followed from that discovery. One result was that primitive and hairy man, sleeping by the fires he succeeded in kindling and feeding, became nude. In another chapter is given an account of the origin of clothes; Prof. Klaatsch stoutly maintained that clothes were worn at first purely as ornaments; he cites ladies' underwear as proof of his contention, but appears to have forgotten that the orang and chimpanzee find out for themselves that an old blanket or a newspaper can serve more than an ornamental purpose. Chapters are devoted to the evolution of speech, of society, of religion, of the home, and of motherhood.

All departments of anthropology are dealt with; in every section the author sets down in clear, unmistakable terms the conclusions he has reached regarding the matters dealt with in his pages. It is the author's courage rather than his judgment which is to be commended. In brief, this book of Prof. Klaatsch's is of value, not because it represents a weighty contribution to anthropology, but because it gives in a readable form the opinions held by an outstanding personality concerning the manner in which man has come by his present place in the world.

(2) Prof. Klaatsch was a polygenist; Prof. Roland B. Dixon is also a polygenist, but of a new kind. The title which he has given his book, "The Racial History of Man," seems to convey the impression that we are to be told how the Negro, the Chinaman, the European, and other well-differentiated races of mankind came into existence. His publishers have given his book all the appearance in paper, type, and binding which marks a standard work. Prof. Dixon's book is in reality a treatise on polygeny; of that he is in no doubt, for he writes:

"The acceptance of such an hypothesis, of the theory that the existing varieties of man are to be explained, not as derived by differentiation from a single ancestral form, but as developed by amalgamation of the descendants of several quite discrete types, places us squarely in the ranks of the long discredited polygenists" (p. 503).

There is no doubt that Prof. Dixon has put himself in his proper category, and we want to know how he came to fall into this position. He, like Prof. Klaatsch, is a thorough-going evolutionist: he is convinced that, in its early evolutionary history, man's ancestral stock progressed in quite an orthodox manner; it diverged, forming many branches, representatives of some of which have been found in a fossilised form in Java and Piltdown, etc. But there came a time—the date is not explicitly stated—when only eight branches—or human types—were left. We are told the names of these. There was (1) the *proto-Australoid*, cradled somewhere round the Indian Ocean; (2) the *proto-Negroid*, whose home was in Africa; (3) the *Mediterranean*, living in Asia to the east of the Mediterranean; (4) the *Caspian*—a new name for our old friend the Caucasian—living in Asia, north and east of the Caspian; (5) the *Mongoloid*, and (6) the *Palæ-Alpine*, neighbours on the central plateau of Asia; (7) the *Ural*, of uncertain nativity, but placed in the meantime in Eastern Russia; (8) the *Alpine*, also a native of Asia. For some reason, which the author does not mention, these eight primitive types of man, living in and native to diverse regions of Africa and Asia, began a great game, which can only be described as that of "anthropological chairs." They all started moving round the world, into each other's countries, and mixing in the most promiscuous way. Out of this old-world game came our modern races—Negro, Negrito, Australian aborigine, Europeans of all sorts, Egyptians, Chinamen, Red Indians, and Lapps. The difference between one modern race and another wholly depends, according to Prof. Dixon, on the proportion in which the eight original races were

[1] Klaatsch's theory was discussed at some length in the pages of NATURE of Nov. 24, 1910 (Vol. 85, p. 119).

employed in their compounding. The Eskimo, one of the most distinctive races of mankind, and marked by unmistakable Mongolian features, has nothing of the Mongol in him, according to Prof. Dixon, but is compounded from the types which make up the peoples of Western Europe, namely, the Mediterranean, Caspian, and Ural types. To the fashioning of Englishmen all the original eight primary types of mankind have been employed, including, of course, the Mongol, the proto-Negroid, and the proto-Australian.

Prof. Dixon came by his discovery in the simplest way possible. To recognise members of his original types, in any race or people whatsoever, he employed three measurements of the skull, its length, width, and height, and two of the nose, its height and width. If the head, according to his standard, was long and low and the nose broad, then the individual with such proportions, no matter what the colour of the skin, texture of the hair, proportion of the body, and general appearance might be, was a proto-Australoid; but if the nose was narrow, this alters the case: the individual is a Mediterranean. But if the head was long and high and the nose narrow, then the individual possessing such proportions must be placed in another category, that of the Caspian archetype. In discussing the distribution of the proto-Australoid type in Europe, Prof. Dixon proves its presence in Germany in neolithic times by citing two skulls of that date with particularly wide noses. In his table (p. 477) the width of the nose is given as 23 mm., the height as 48 mm., and the proportion of width to height as 57·9 per cent. But if the reader will work the sum out, he or she will find it is not 57·9 but 47·9 per cent. On this slip in his arithmetic Prof. Dixon builds his hypothesis of a proto-Australoid stock in neolithic Europe. In other cases his arithmetic may be right, but his methods and inferences have just as little foundation in fact as in the former case. Why, every anthropologist knows of families where one brother, on Prof. Dixon's scale, would be a proto-Negroid, another a Caspian, another a Mediterranean or Ural, while among the sisters of the same family might be found representatives of his remaining types.

To make quite clear the methods pursued by the professor of anthropology in Harvard University, let us suppose that the history of the various makes and types of motor-car is unknown, and that Prof. Dixon has undertaken to discover how the various types have come into existence. If he applied the method which he has employed to unravel the history of human types, he would measure the length, breadth, and height of the body of each type of car and the width and height of the bonnet, and with these measurements to work on would deduce the history of each make of car. Essential points concerning the engine, the gearing, steering, the system of ventilation and lubrication, and all the essential details which go to the proper working of a car, are to be passed unnoted. When the matter is put in this way, even those who regard cranial measurements as sacrosanct will understand the value to be attached to Prof. Dixon's account of the evolution of human races.

(3) In Dr. Donald A. Mackenzie's pages we have Western Europe pictured as a corridor leading from Egypt, or some adjacent part of Africa or Asia, to Britain. In ancient times there passed along this corridor a continuous procession of various types of men, each carrying its peculiar customs and beliefs. The Cromagnon people, in Dr. Mackenzie's account, head the procession; they came from east of the Nile, and brought to Europe and to England the religious beliefs of their native land. They were followed by the "Solutreans," who, we are told, came from about Somaliland. After them came the "Magdalenians," the "Azilians," and the "Tardenoisians." The Magdalenians, we are informed, were really Cromagnon people. The only folk who did not come the usual way and from the usual source were the "Maglemosians"; they came from Siberia to the Baltic, and brought the dog to Europe; they were blonds of the Nordic type. So far as the writer knows, only one fragmentary skull of the Baltic kitchen-midden people (the Maglemosians) has so far been found; we know nothing of a Nordic people in Siberia in early neolithic times; there are not half-a-dozen human skeletons, or fragments of skeletons, which can be ascribed to people who made the Azilian and Tardenoisian types of weapons or implements. We really know nothing of these people whom Dr. Mackenzie has made to move so briskly towards Britain in ancient times.

Perhaps it will be fairest to let him speak for himself:

"For a long period, extending over many centuries, the migration 'stream' from the continent appears to have been continuously flowing. The carriers of neolithic culture were in the main Iberians of Mediterranean racial type—the descendants of the Azilian-Tardenoisian peoples who used bows and arrows, and broke up the Magdalenian civilisation of Cromagnon man in Western and Central Europe. This race appears to have been characterised in north and north-east Africa. 'So striking,' writes Prof. Elliot Smith, 'is the family likeness between the early neolithic people of the British Isles and the Mediterranean and the bulk of the population, both ancient and modern, of Egypt and East Africa, that the description of the bones of an early Briton of that remote epoch might apply in all essential details to an inhabitant of Somaliland'" (p. 126).

For the latter part of his statement Dr. Mackenzie

has the highest authority, but, so far, the writer has heard of no one who has made and published a detailed comparison between the bones of neolithic Britons and those of modern Somalis and Egyptians. It is highly desirable that an investigation of this kind should be made, for it is difficult to believe that there is any degree of Somali blood in modern England.

ARTHUR KEITH.

The Orders of Insects.

Manual of Entomology: with Special Reference to Economic Entomology. By Prof. H. Maxwell Lefroy. Pp. xvi + 541 + 4 plates. (London: E. Arnold and Co., 1923.) 35*s.* net.

THE classification of insects has passed through many changes, and most of the systems proposed have been primarily based upon characters afforded by the wings, mouth-parts, and metamorphoses. During the last fifteen years entomology has suffered from an over-exercise of the analytic faculty on the part of morphologists. One result of their activities is seen in the increasing number of subdivisions of the class Insecta, and some eminent authorities even dismember the latter as a whole. The tendency is to emphasise differences rather than the features which groups reveal in common. In some cases the same morphological characters in different orders are not credited with proportional values. The result, as might be anticipated, is a condition of instability with no very clear conception of what is to be regarded as an order and what is not.

The foundations of the modern classification of insects were laid by Brauer in 1885. He recognised the fundamental division of the Insecta into the two sub-classes Apterygogenea (Apterygota) and Pterygogenea (Pterygota)—members of the former being primitively apterous and those of the latter winged, or in some cases secondarily apterous. Brauer also did much towards dividing the old assemblage Neuroptera into separate sections, each of ordinal value. In 1899 Sharp established a system partly modelled upon that of Brauer, and he introduced the terms Exopterygota and Endopterygota, in order to discriminate between those orders in which the wings develop outside the body, and those in which they remain internal until pupation. He further introduced the term Anapterygota to include those apterous orders which have, presumably, become secondarily wingless. This latter step, however, has the disadvantage of bringing together distantly related groups.

In 1904 Shipley adopted Sharp's system almost in its entirety, but proposed certain new ordinal names with the double object of doing away with the use of family designations for ordinal purposes, and of introducing a system in which the suffix "ptera" is extended to all orders. In the same year Börner proposed a system which recognised the same orders as Shipley (although not necessarily under the same names), with the exception that he adopted a threefold division of the Apterygota, and revived the ordinal name Corrodentia for the Psocoptera and Mallophaga. Four years later Handlirsch launched a revolutionary scheme: he no longer retained the Insecta as a primary division of the Arthropoda, and his system involved their dissolution into four classes comprising no less than 34 separate orders. In America he has found support from Brues and Melander (1915), who added the more recently discovered orders Protura and Zoraptera and, at the same time, elevated the family Grylloblattidæ to ordinal rank, thus recognising altogether 37 orders. Berlese, on the other hand, in his encyclopædic treatise "Gli Insetti" reverts to a simplified taxonomy and diagnoses but nine orders. In a few words, it may be said that centres of disruption exist in the orders Orthoptera, Corrodentia, and Neuroptera as defined by Brauer. Once a condition of equilibrium is attained with respect to these three groups we may be on the high road to something approaching unanimity.

Prof. Lefroy's book is essentially one on the orders of insects. In the preface it is mentioned that the book is based "upon the lectures given as the second of three parts of a course occupying one year of a full training in entomology." This apparently accounts for the absence of any general chapters on structure, biology, or development. On the whole, a very reasonable compromise is made between the radical tendencies of Handlirsch and undue conservatism, and some 26 orders are separately treated more or less in detail. The book is written for the student of applied entomology, and its object is to teach him how to recognise an insect in the field, to determine its sex, to learn about its habits and the methods of control, and to familiarise him with some of the more important monographs or catalogues which provide references to the literature.

The conception of the book is a good one. In carrying it out Prof. Lefroy assumes that the student is working with a collection of specimens which he can handle—illustrations are not very much believed in—and has access to the "Zoological Record," "Genera Insectorum" and the *Review of Applied Entomology* for further information. References consequently do not, as a rule, include the names of the journals concerned, and sometimes only comprise the names of the authors, along with the dates of their publications. This method has very obvious difficulties, and, although

it doubtlessly works all right in Prof. Lefroy's own department, a restriction is inevitably placed on the circle of those who might use the volume—particularly outside the British Isles. Anyway, this is the plan upon which the student is intended to proceed.

In the preparation of the volume the services of eight past or present students of the Imperial College have been enlisted—a certain number of orders having been allotted to each. The necessary information having been collected and written up, the whole was then, presumably, sifted and edited by Prof. Lefroy. This unorthodox method has its pitfalls. The various sections, each of which is devoted to a separate order, are of rather unequal merit—as might be expected—the one devoted to the Neuroptera being probably the best. Also, the book contains a number of misprints which suggest hurried proof-correcting, and contains errors which, if repeated in an examination paper, would tell considerably against a candidate. For example, on p. 10 the extra spiracles of Japyx are stated to be on the prothorax: on p. 41 the cervical sclerites are mentioned as articulating the thorax to the abdomen: on p. 87 the mandibles of the nasute caste of termites are stated to form a kind of beak through which a secretion can be exuded at will: on p. 457 Glossina is credited with dropping its larvæ one at a time while in flight.

On the other hand, almost all the families of insects are mentioned, and most of them treated separately, which, in itself, is quite an achievement: in some cases even the sub-families are enumerated and commented on. The book also contains a good deal of information not otherwise very accessible. It is admirably printed, but the price seems rather high. The four half-tone plates are excellent, and the text-figures, for the most part, serve their general purpose. A. D. I.

Photographic Science.

Photography as a Scientific Instrument. A Collective Work by A. E. Conrady, Charles R. Davidson, Charles R. Gibson, W. B. Hislop, F. C. V. Laws, J. H. G. Monypenny, Dr. H. Moss, Arthur S. Newman, Dr. Geo. H. Rodman, Dr. S. E. Sheppard, W. L. F. Wastell, Wilfrid Mark Webb, Col. H. S. L. Winterbotham. (Applied Physics Series.) Pp. vii + 549 + 21 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1923.) 30*s*. net.

OWING to the enormous advances which have been made in the various branches of science, recent years have seen the publication of numerous monographs written by specialists in one particular domain. Chemistry and physics have been well catered for in this respect, but, at all events in Great Britain, there has been no series of monographs dealing with photography, a subject which may be considered as belonging to physical chemistry. The present book, to some extent, supplies this want. It consists of fourteen chapters written by thirteen different men, each of whom is an acknowledged authority on the subject about which he writes. Although it would not be correct to describe the various chapters as monographs, since a complete description of the particular branch under consideration is not attempted, yet in each one is brought together a mass of knowledge which has hitherto been scattered far and wide in the literature, or has remained embodied as "experience" with individual workers.

The first four chapters treat of the history, optics, and chemical and physical processes of photography: they may be considered as dealing with the more purely scientific side, whilst the remaining ten chapters treat of the application of the art in various branches of science and technology.

When dealing with a book of this kind the reviewer is necessarily subject to limitations: he cannot have a knowledge of all the subjects treated, and consequently is attracted by some chapters rather than others. From the purely scientific point of view, those due to Prof. Conrady and Dr. Sheppard are especially worthy of mention. The former bases his treatment of the photographic lens system on the Abbe form of the general theory, and deals with it from the point of view of the user rather than that of the designer and computer. The properties of lens systems, and the various classes of aberrations to which lens systems are subject, are treated in a surprisingly simple manner. The practical photographer will be especially interested in "The Experimental Determination of the Constants for any Lens System," and with the explanation of depth of focus, ghost images, flare spots, etc. He will also find that a perfect lens system is impossible, the best obtainable being the result of a large number of compromises leaving always small residuals of aberration. Such knowledge is important to the purchaser, who will not then expect too much from the makers or sellers, who are generally silent on such points.

Since all the applications of photography depend on having the necessary sensitive material with which to work, it is natural that Dr. Sheppard's chapter is the longest in the book. The author has been, so to speak, "born and bred" in the subject, and, possibly because of this, in some of his publications he has been apt to forget that his readers have not the same acquaintance with the subject as he has. In this chapter, however, Dr. Sheppard has not fallen into this error, and the reviewer does not know of any other account which covers the facts so clearly and lucidly. One failing,

however, Dr. Sheppard does not seem able to overcome. Chemical equations seem to be beneath his notice; in particular, the equation representing the reaction between ferrous sulphate and silver nitrate (p. 140) contains so many errors that one cannot fail to notice them.

The photographic methods used in astronomical photography are described by C. R. Davidson, and Dr. Moss gives a valuable selection of examples of the application of photography to physical investigations. "Photomicrography" is covered in two chapters, J. H. G. Monypenny dealing with its application in metallurgical and engineering research, whilst Dr. Rodman, in a more popular manner, describes its application in histology, bacteriology, and pathology. There is necessarily some duplication in these chapters, and, as is not to be wondered at, differences of opinion. Similar remarks as to overlapping hold with respect to the chapters on "Photographic Surveying," by Col. Winterbotham, and on "Aeronautical Photography," by Major Laws. The differences in view-point obtained are, however, all the more instructive.

Mr. Wastell describes the various colour processes, from that of Lippmann to the latest form of kinematography in colour; and Mr. Hislop deals with the application of photography to various printing processes in monochrome and in colour. The last two chapters deal with the "Technics of Kinematography" and "The Camera as Witness and Detective."

The book is a valuable one, and should be of interest not only to specialists in photography, but also to the public in general. T. S. P.

Our Bookshelf.

The British Pharmaceutical Codex, 1923: an Imperial Dispensatory for the Use of Medical Practitioners and Pharmacists. (Published by direction of the Council of the Pharmaceutical Society of Great Britain.) New and revised edition. Pp. xx + 1669. (London: The Pharmaceutical Press, 1923.) 30*s*. net.

THE British Pharmaceutical Codex was compiled by a committee of experts, working under the direction of the Council of the Pharmaceutical Society, and was intended to afford to pharmacists and physicians a ready means of obtaining trustworthy information concerning drugs and medicinal preparations in general use throughout the British Empire. It has fulfilled its purpose well. Works of this type, however, quickly lose their value, and, notwithstanding the publication of supplements in 1915 and 1922, a new issue was overdue. The text of the book bears on every page evidence of thorough and careful revision, and it is now well abreast of pharmaceutical and medical practice. Among the new monographs that attract attention is that on acriflavine. Here the constitution and preparation of this important antiseptic are explained, and a full page is devoted to an exposition of its advantages in medical and surgical treatment, the form in which it is best prescribed, and the synonymy of its derivatives, euflavine, homoflavine, and proflavine. Chloramine-T and the chlorinated antiseptics, eusol, Dakin's solution, and Daufresne's solution, are similarly discussed. The thoroughness evident in these monographs characterises the whole work, and it is just this that makes the Codex so valuable and trustworthy. Under the heading "Curationes" a general description of surgical dressings and the methods by which they may be tested is given; it is curious to note that the lint of the Codex is composed entirely of cotton, whereas the presence of cotton was formerly considered objectionable on account of its supposed irritating nature. Insulin, thyroxin, and other drugs of very recent origin find a place in the work. The list of test solutions and microscopical stains is a very restricted one, and scarcely justifies its title. The whole work is remarkably free from errors, and the committee entrusted with its preparation may be congratulated on the success of their efforts. It is to be hoped that the Council will not, from motives of economy, unduly delay the appearance of a new edition, so that the book may always be kept well up-to-date.

Vom Gleitflug zum Segelflug: Flugstudien auf Grund zahlreicher Versuche und Messungen. Von Gustav Lilienthal. (Volckmanns Bibliothek für Flugwesen, Band 15.) Pp. 159. (Berlin-Charlottenburg: C. J. E. Volckmann Nachf. G.m.b.H., 1923.) 2.50 marks.

"EINE Kritik meiner Arbeiten nur vom grünen Tisch aus, ohne meine Experimente und Messungen nachzuprüfen, lehne ich von vornherein ab." This is the beginning of the last paragraph in the book by Herr Gustav Lilienthal, the brother and collaborator of the famous Otto Lilienthal. He is led to take up this uncompromising attitude because, he claims, the results of his lengthy and laborious measurements have already been criticised in a manner suggesting that they have not been properly examined and understood.

Herr Lilienthal discusses the old problem of soaring or sailing flight. He maintains that the present form of aeroplane is due to the misdirection of effort caused by the War, when aeroplanes were required at once and in as large numbers as possible, with the result that the type then known became standardised for all purposes and all nations. The author's view is that the modern aeroplane, in which the wings do the sustaining while an engine is used for propelling, is an imitation of the beetle rather than of the bird. He hopes that the effect of the revival of gliding will be to cause the aeroplane to approximate more to the bird form, with the wings supplying the propulsion as well as the sustentation.

Meanwhile, Herr Lilienthal discusses how the sailing flight of certain birds is possible. He claims to have established experimentally that the wind supplies the work required for sailing flight, by means of its property of making bodies suspended in it turn through about 4° upwards. Further, the camber in a bird's wing produces an eddy below the wing, with the result that the work supplied by the wing is used for both sustentation and propulsion. It is difficult to see why

a horizontal wind should produce the 4° turn which Herr Lilienthal claims to have measured, but it is a suggestion worthy of consideration, and one that may lead to interesting developments. S. B.

Les Principes de la physique. Par Dr. Norman R. Campbell. Traduit et adapté en Français par Mme. A. M. Pébellier. (Nouvelle Collection Scientifique.) Pp. xix + 200. (Paris : Félix Alcan, 1923.) 8 francs.

A TRANSLATION into French of Dr. N. R. Campbell's book entitled "Physics, The Elements," was suggested to the author by M. Émile Borel, who had been called upon for a notice of the volume in the *Revue philosophique*. But the length of the original imposed the necessity for considerable abbreviation ; one-third only of this smaller book is a textual translation, the rest is an abstract, the developments of several pages being sometimes reduced to a few lines. Mme. Pébellier has carried out both the paraphrase and the translation, and her difficult task seems to have been performed most efficiently. The book is rendered more interesting, especially to the English reader, by the preface contributed by M. Borel. He emphasises the great importance of the treatise, arising from the fact that the author is an experimental physicist, and moreover an English physicist. Experimental and theoretical work correspond to different forms of activity, and perhaps to different forms of thought. Continental physicists, whether they are French, German, or Italian, are perhaps less purely physicists than the English. It may at least be affirmed that the latter have certain particular qualities, qualities which sometimes shock the savant of the Continent but in practice produce remarkable results. M. Borel proceeds with an interesting discussion of the language of physics, which he regards as intermediate between the exact language of mathematics and the vaguer language of the vulgar tongue, in which words have only a *statistical* definition. In its new form Dr. Campbell's work should appeal to a wide circle of readers.

The Poulsen Arc Generator. By C. F. Elwell. Pp. 192. (London : Ernest Benn, Ltd., 1923.) 18*s*. net.

As there are more than 20,000 kilowatts of arc transmitters in use to-day, it is highly probable that they will remain in use for many years to come. The British Post Office adopted a 250 kw. Elwell-Poulsen arc generator for the first link of the Imperial Wireless Chain connecting Leafield with Cairo. These two stations are now in operation at two-thirds of the cable rate. The same type of generator is also used at Northolt for communication with the Continent. The Dutch Government is installing a 2400 kw. Poulsen arc, the largest in the world, in Java, to enable it to communicate directly with its colonies. As the author points out, it is the one good system which is not covered by a multitude of patents thought by many to be employed to dictate the terms and conditions under which the other systems may be used. The book begins with a historical introduction, due stress being laid on Duddell's discovery of the musical arc. The arc generators are then described, and finally clear descriptions are given of the methods and apparatus used for signalling and the application of the generator to radio-telephony.

Clinical Laboratory Methods. By Prof. R. L. Haden. Pp. 294 + 5 plates. (London : H. Kimpton, 1923.) 18*s*. net.

THE author of this book has adhered strictly to his object of presenting methods of carrying out clinical laboratory work without in any way discussing the interpretation of the results. The volume is therefore essentially a manual for the laboratory worker. The various tests are described briefly, but with attention to every practical detail, and references to original articles are provided with most of the descriptions. The author has limited himself as a rule to one method for each quantitative estimation, apparently with the rather narrow view that one method is suitable in all circumstances. The examination of gastric contents differs considerably from the examination generally carried out in Great Britain, and no consideration is given to the fractional test meal. The illustrations, with the exception of those of blood cells, are very good. Making allowance for slight differences in terminology, the clinical pathologist will find in this book a clear description of the laboratory methods in general use.

Textile Chemistry : an Introduction to the Chemistry of the Cotton Industry. By F. J. Cooper. Pp. ix + 235. (London : Methuen and Co., Ltd., 1923.) 10*s*. 6*d*. net.

MR. COOPER'S book covers a good deal of ground in a brief but clear fashion. It reads more like a note-book than a text-book, but is obviously the work of a number of years of teaching, and should be useful to students in technical schools, for whom it is intended. Besides the elementary chemistry which serves as an introduction, the author discusses its applications to the textile industry, and among other things the natural fibres, the chemistry of coal, oils, industrial waters, sizes, bleaching, dyeing, and mercerising. Those engaged in teaching the subject will find the book useful and helpful. There are a few minor inaccuracies : a "base" need not contain a metal (p. 66) ; nitric oxide is not absorbed by sulphuric acid (p. 69). The descriptions of experiments are not always adequate, and some of them (as that shown in fig. 119) can scarcely have been tried successfully.

Radio Telegraphy and Telephony. By Prof. E. W. Marchant. Pp. ix + 137. (Liverpool : University Press of Liverpool, Ltd. ; London : Hodder and Stoughton, Ltd., 1923.) 6*s*. net.

A VERY large number of books on radio telegraphy and radio telephony have recently been published. Many are of little use to the general scientific reader because they are too elementary ; others fail because they are too technical, the authors revelling in technical terms which are in general very vaguely defined. Prof. Marchant seems to have hit on the happy mean in this little volume. The science is accurate, the descriptions are good, and the information is up-to-date. To make assurance doubly sure the author has added a glossary giving good definitions of the technical words used in the text. This book can be recommended to the reader who wants to understand the principles utilised in radio telephony, broadcasting, and directional radio signalling.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Some New Commensals in the Plymouth District.

WHILE collecting by digging on the shore at Millbay, Salcombe, in April this year, I found three consecutive pairs of Synapta and a polynoid worm living together, and at the same time three distinct associations of the brittle star, *Ophiocnida brachiata*, and a small mollusc. These finds led to five later

FIG. 1.—The brittle star, *Ophiocnida brachiata*, with the polynoid, *Harmothoë lunulata*, clasping and curving over the disc, opposite the arrow head and alongside the projecting arm which is broken off short; and the mollusc (M), *Montacuta bidentata*: three animals living associated together buried in muddy sand at Salcombe. $\times$ *ca.* $\frac{3}{2}$. (From a photograph by Mr. R. S. Clark.)

monthly visits during the best spring tides, and resulted in the observations given below.

The polynoid, *Harmothoë lunulata*, was found in muddy sand at Salcombe on adjacent beds with six different animals belonging to two different phyla and four different classes, but the more interesting point is that the size of the polynoids forms on the whole an increasing series approximately as follows: *Harmothoë lunulata*, a few to 10 mm., with *Ophiocnida brachiata*, and curved round the disc or over the mouth (Fig. 1); *H. lunulata* (var. *synaptæ* St. Joseph), 15 to 20 mm., with *Synapta inhærens* and *S. digitata*, and also occasionally with *Phascolosoma pellucidum*. On the same beds occur larger specimens of a polynoid somewhat different in general appearance from the small *Harmothoë lunulata* just mentioned, but they appear to be merely later-growth stages of the same species, and agree generally with the var. *nigra*, Alæjös. Specimens of this form about 20 to 30 mm. were taken with *Phascolosoma vulgare*, and of 35 to 50 mm. with *Amphitrite Edwardsi*. Further work will be required to put this last observation on a secure basis, but the animals can only be obtained by special search in small numbers at considerable intervals of time. There is little doubt, however, that this species of Harmothoë at Salcombe starts life commensally with Ophiocnida, and changes its mate as it grows bigger and requires more accommodation in the burrow provided by the messmate, until it finally consorts with polychætes up to 30 cm. long, such as *Amphitrite Edwardsi*.

Harmothoë lunulata was also taken at the mouth of the River Yealm with *Synapta inhærens*, and will no doubt later be found in the same association in Plymouth Sound.

During the same expeditions the almost constant association of the mollusc *Montacuta bidentata* [1] with *Ophiocnida brachiata* was confirmed. The mollusc in this case is frequently found in numbers just below or above the disc, and occasionally under an arm in company with *Harmothoë lunulata* young. The same mollusc was taken also but less frequently with the Gephyrean, *Phascolosoma pellucidum*, and occasionally with Nereis. With this Gephyrean, however, was found fairly constantly the messmate *Lepton Clarkiæ*,[1] which was fairly frequently present in groups of 4 to 7, and sometimes attached to the skin of the blood-worm.

On both shores at Salcombe another Harmothoë sp. B, not yet identified, was taken in tubes with one, and not in tubes with other species of Nereis. The same species was taken by careful work also in Rum Bay, Plymouth Sound, alongside or under the tentacles of *Amphitrite gracilis*, *Polycirrus aurantiacus*, and another species of Polycirrus, and at the same time *Harmothoë marphysæ* was rediscovered with *Marphysa sanguinea* in Plymouth Sound after a long lapse of years. The same Harmothoë sp. B was also taken with Nereis in beds at the River Yealm. It is an interesting fact that Sir Ray Lankester took a similar polynoid under the tentacles and in the tubes of *Terebella* (*Polymnia*) *nebulosa* at Herne so long ago as 1865.

The frequency with which the associates mentioned above occurred apart from each other was noted during the collecting work, and found to be low except in the case of *Phascolosoma pellucidum*, which occurs in thousands in a few square yards of ground.

In none of these cases of association or commensalism can a reason for it be asserted with any certainty. The frequent occurrence of polynoids, however, at the bases of the tentacles of polychæte commensals, as Polycirrus, or in or near the grooves of other polychætes, as Amphitrite, Nereis, Chætopterus, or the grooves of Ophiocnida, suggests the pilfering or scavenging of food-material. In the cases of Montacuta and Lepton it is clear that food-material is abundant in the burrows they inhabit, as their shells are often covered with Polyzoan polyps, and in addition various Foraminifera are not uncommon in the mouths or in the region of the burrows.

Indeed, the variety of associates of some commensals suggests, on the other hand, that an inhabited burrow may be simply and mainly a harbour of refuge, which is used so frequently that the inhabitants learn to know and tolerate each other, while at the same time not necessarily depending directly in any particular way on each other for food.

Conductivities of Aqueous Salt Solutions.

IN the course of an investigation carried out during the last two years on the transference numbers and conductivities of certain aqueous salt solutions, we have come across a simple relation which appears to us of interest and importance.

The specific conductivity of an electrolyte (κ) as usually measured, refers to one *centimetre cube* of the solution. We found it desirable, when working with concentrated solutions, to compare figures given by volumes of electrolyte containing always *one gram of water*. If the solution in question contain x grams of salt per thousand grams of water, and is of density d, then the volume of solution containing one gram of water is $\frac{1000+x}{1000d}$. Multiplying this term by κ, we obtain a magnitude which we will denote by κ', which is the conductivity between electrodes one cm. apart of an amount of the solution containing one gram of water. At high concentrations, the viscosity of the solution is a factor which cannot be neglected. Making the simplest assumption, *i.e.* that conductivity and fluidity are proportional, we arrive at a corrected conductivity,

$$\kappa' \text{ corr.} = \frac{1000+x}{1000d}\kappa\eta.$$

Multiply by 1000, and we have the conductivity under the same conditions due to an amount of solution containing 1000 grams of water. If now this be plotted against x/M or the weight molar concentration (mols per thousand grams of water), the result is a curve which, in the cases of potassium, sodium, and lithium chlorides, becomes nearly linear after x/M has exceeded 0·5-1, and remains so up to the limit to which we have so far carried our measurements ($x/M = 3$ to 5, depending on the electrolyte). We have plotted the conductivity, density, and viscosity data of other observers for certain other solutions, and have obtained similar results.

Expressed verbally—if a thousand grams of water are put between electrodes one cm. apart and one of the salts in question gradually added, the increase in conductance of the cell (corrected for viscosity change) brought about by dissolving, say, an extra one-tenth gram equivalent of salt is nearly independent of the concentration of the solution when a certain limit of concentration has been exceeded. The slope of the curve is given by

$$\frac{(1000+x)\kappa\eta}{d\frac{x}{M}}.$$

A curve of the same slope is got if the molar fraction of the salt in the solution is plotted against the conductance (corrected for viscosity and measured between electrodes one cm. apart) of a mol of solution: that is, within the limits mentioned, the corrected conductance of a solution is practically proportional to the ratio salt molecules/total molecules.

This relation, obtained by considering, not, as is customary, the conductance of a fixed weight of salt to which increasing amounts of water are added, but the conductance of a fixed weight of water to which increasing amounts of salt are added, would appear to have considerable implications in several directions for the theory of strong electrolytes. These will be considered, and the data more fully presented, elsewhere.

We have written this preliminary note as a result of reading recently a paper published some months back by Linde (*Zeitsch. Elektroch.* 29, 163, 1923) and not previously noticed, as its title did not indicate any particular bearing on our work. In this paper the author has plotted $\kappa\eta$ against $\frac{100x}{1000+x}$ (*i.e.* the specific conductivity corrected for viscosity against the weight percentage of the salt in the solution) for aqueous lithium and calcium chlorides solutions up to very high concentrations (far higher than any we have so far measured). He finds a linear relation up to 30 per cent. lithium chloride and 20 per cent. calcium chloride respectively, after which the curves bend. The essential difference between his method of plotting and ours is that we take into our conductance expression the density of the solution. If his curves are modified in this way, the changes in direction at the high concentrations become far less marked, and their courses at more moderate concentrations, whilst becoming somewhat less linear, closely approximate in type to those found by us for solutions of lithium chloride and other salts.

The London Fogs of November 25-27, 1923.

THE accompanying graph (Fig. 1) shows the hourly variation in the quantity of suspended impurity, that is, sooty matter, in the air of London (Westminster), which was chiefly responsible for the recent smoke fogs. This curve shows clearly that the maximum density of the smoke fog occurred about mid-day, and there was a rapid increase in density which coincided

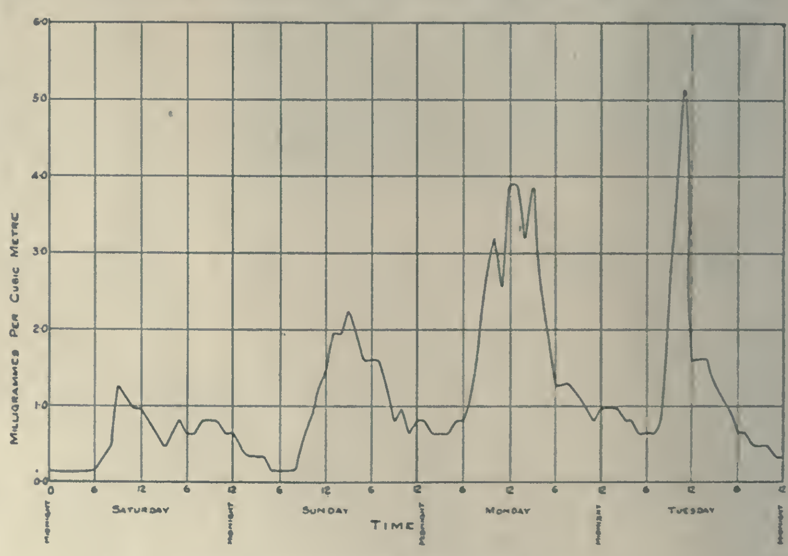

FIG. 1.—Suspended impurity in the air of Westminster, November 24-27, 1923.

with the period of lighting up of fires in the morning. The figures from which the curve is plotted were obtained from my automatic recorder, designed for the Advisory Committee on Atmospheric Pollution. When a large number of days are averaged, and

plotted, the distribution over the 24 hours is similar but more uniform, and it can even be seen that the maximum is reached later on Sundays than on week-days (Eighth Report Advis. Comm. on Atmos. Pollution, p. 30).

Records taken in Westminster by my impact apparatus at the height of the recent fogs showed about 50,000 solid particles per cubic centimetre, and very little indication of water drops. These particles averaged a little more than 0·5 micron in diameter, and there was a tendency to a rounded, kidney shape, with a fair number of small transparent spheres of about the same diameter.

With reference to the cause of the "London Particular," the view is generally held that a London fog consists of condensed water particles dirtied by smoke and oily hydrocarbons (Carpenter, "London Fog Inquiry," 1901–2), and this view follows naturally from the fact that during London smoke fogs there is very often a dense water fog in the surrounding country. There are, however, certain indications which point to a different conclusion and suggest that a London smoke fog, such as we have experienced recently, occurs at the same time as the surrounding water fog, not because it is a result of the latter, but because of the conditions which favour water fog. I have, therefore, been forced towards the view that the smoke fog of London does not consist of water particles dirtied by smoke, but almost entirely of smoke particles alone. In support of this are the following facts:

(*a*) During the recent fogs when the sun was visible at all it appeared as a red ball, thus pointing towards the presence of finely divided suspended matter, and not towards large water globules.

(*b*) Records taken by my impact method during London smoke fogs show little evidence of water drops, which, if present, would be obvious; but there are always immense numbers of small smoke particles.

(*c*) It is not unusual in coming up to London from the country during foggy weather to find a dense white fog in the country, with a limit of visibility of perhaps 50 yards, giving place to a yellow fog in London with a greater limit of visibility; thus, while a large amount of smoke can always be detected, there must be a great reduction in the quantity of water in the London fog, since in spite of the smoke addition visibility improves.

(*d*) The air over London is warmer than in the country surrounding, and although the combustion of large quantities of fuel supplies a certain amount of water to the air, it seems probable that condensation of water in London to form fog would normally be much less than in the surrounding country. There are about 17,000,000 tons of coal burnt per annum in London, and assuming a wind of 2 miles per hour and an inversion of the lapse rate of temperature at about 400 feet, a condition likely to be met with during foggy weather, this amount of coal would keep the air immediately over London about 13° F. warmer than in the surrounding country.

(*e*) The hourly incidence of suspended impurity, as shown in the curves, varied exactly with the darkness and apparent density of the fogs as judged by the eye.

Doubtless in the early morning the conditions which cause a water fog in the country also cause a similar fog in London, if not so dense; but as the day advances the smoky fires add their soot and heat to the air, the latter evaporating the water and the former replacing it by soot.

Fires are notoriously smoky shortly after lighting until they get well heated up, and we find, as a rule, that the smoky London fog commences in the morning about the time of fire lighting and dies away gradually as the fires become well established; while it is usually at a minimum between midnight and early morning. If the natural ventilation over the city fails to carry away the smoke produced, there is sufficient evolved in the morning in three or four hours to provide Londoners with the densest smoke fog they have ever experienced. Such a fog contains 5 or 6 milligrams of soot per cubic metre, and this can be easily supplied by the 40 or 50 tons of soot evolved per hour by the chimneys of London.

Assuming the correctness of the above, we may draw the following inferences:

(1) The air over London being warmer than its surroundings, water fogs will be fewer or less dense during the day than in the country.

(2) The "London Particular" can be entirely prevented by abolishing smoke.

Upper Air Conditions after a Line-Squall.

METEOROLOGISTS are indebted to Wing-Commander L. W. B. Rees for some very valuable observations during two aeroplane ascents at Cranwell (Lincs.) on October 19, showing the change which took place in upper-air conditions during the passage of a "line-squall" or, in the phraseology of Bjerknes, a "cold front." Observations of this kind are sufficiently rare, and the features exhibited by the present ones are so specially interesting that it seems very desirable to lay some emphasis on them.

The accompanying diagram (Fig. 1) shows the details of the records. The first ascent (dotted line) commenced at 9.15 A.M., and was made in front of the line-squall in the "equatorial air," the origin of which has now been traced back, on the charts in the Meteorological Office, to a low latitude. The figures against the curve show the relative humidity at various levels, the corresponding number of grams of water vapour per kilogram of air being given in brackets. It is necessary to remark that the report of cloud and rain encountered is not inconsistent with the apparently unsaturated condition of the air, for the cloud was not necessarily continuous throughout the thickness indicated, and, further, the instruments were read on the way up when the clouds were only just commencing to thicken and form rain. No rain reached the surface until 10 A.M. The line-squall occurred at 10.5 A.M., marking the arrival at the surface at Cranwell of the "polar air" which has been traced back to the neighbourhood of Greenland. The usual line-squall features were recorded—heavy rain, sudden veer of wind from S.S.W. to W., and sudden fall of temperature of 9° F. All the rain, 2·1 mm., occurred between 10 A.M. and noon, and presumably fell through the undercutting wedge of colder air from the "equatorial air" above. The second ascent (full line) commenced at 2.15 P.M. in response to a request by wireless telegraphy from the Forecast Division of the Meteorological Office, Air Ministry, where the first record had been received and the weather charts showed how valuable another would be.

The second record shows that the aeroplane left the ground in the "polar air" and penetrated the "equatorial air" above, but what is particularly striking is the extreme dryness of the intermediate layer extending from about 5000 ft. to 9000 ft. When a sharp discontinuity is absent between two different air currents the effect is usually attributed to mixing at the interface, but the present intermediate layer some 4000 ft. thick cannot possibly have been a

"mixing layer," for it contained a much smaller proportion of water vapour per mass of air than the layers above and below. The following considerations suggest that it belonged purely to the lower current and was, indeed, the only genuine "polar air" surviving over Cranwell.

Let the shaded figure (*a*), in the inset diagram, represent, schematically only, a vertical section (vertical scale much magnified) of a "tongue" or "globule" of cold air which has not long since penetrated from a cold source into a warmer environment. Subsequent translation and lateral spreading under gravity may lead to a condition, now at a distance from the cold source, represented by fig. (*b*), the line-squall taking place, say, at the right-hand edge. A contribution to the study of such motion has been made by Exner [Sitzungsber. Akad. Wiss. Wien, IIa, 127, 1918, pp. 795-847]. In the transition the air at A descends to C, while the surface air remains at the surface, so that the higher a layer was originally the more it is warmed adiabatically. Hence

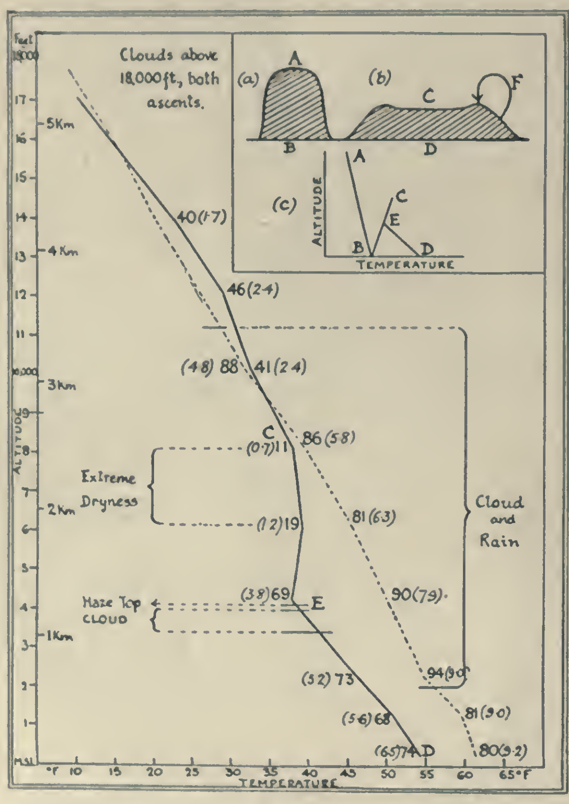

FIG. 1.

if the original lapse-rate, represented by AB in fig. (*c*), is less than the adiabatic, as is reasonable for air cooled mainly from the surface in high latitudes, it will become, from this cause alone, more remote still from the adiabatic, like CB, where AC is the slope of the "dry adiabatic." A more precise mathematical treatment of such a change of lapse-rate has been given by Margules (Exner, "Dynamische Meteorologie," 1917, p. 80). Any change of pressure, at a given level, during the transition would produce effects which would not appreciably modify that demonstrated. The sinking of the globule thus tends towards greater stability and therefore to oppose turbulence. But in passing over a relatively warm surface such as the Atlantic the cold air mass would receive heat from below, and this would be diffused upwards as far as the turbulence originating at the surface is able to penetrate in the face of the stabilising action of the sinking. A lapse line like CED would result, where E is the upper limit of mixing.

In the present case there is clear evidence of the upper limit of turbulence in the "haze-top" reported at about 4000 ft., and the layer ED in the main diagram was accordingly the one which had been warmed from below; it possessed the "dry adiabatic" lapse-rate of temperature indicative of thorough mixing, and was fairly humid, with cloud at the top, owing to water vapour, evaporated over the Atlantic, having been stirred up at the same time as the layer was warmed. The layer CE, on the other hand, was, on this view, one which had succeeded in remaining non-turbulent, and was really the only genuine "polar air" which reached Cranwell, still possessing the original low polar water vapour content and, neglecting radiation, its original potential temperature. This view is strengthened by remarking that, although the moderate decrease of humidity and small rise of temperature indicated by the upper parts of the two records may be explained, using a Hertz diagram, by supposing the "equatorial air" to have ascended, lost some moisture as "cold front" rain, and descended again, as suggested at F in fig. (*b*), no such explanation can be applied to the extremely dry layer discussed above, for the air would have to be taken to an unreasonably great height, and would also arrive back with far too high a temperature. It does not seem, therefore, that the intermediate layer can have been evolved out of the "equatorial air," and these interesting records are accordingly to be interpreted as showing that the air of polar origin over Cranwell was in all probability a "tongue" or "globule" about 9000 feet thick with the lower half partially "depolarised." Subsequent weather charts suggest that it was soon replaced again by a warmer air current right down to the surface.

Such pairs of records as this, near "cold fronts," are uncommon, the nearest approach amongst those published in the Daily Weather Reports being in the issues of October 14 and 15, 1921, two ascents at Baldonnell (Dublin) having exhibited similar features to the present. They are also important as bringing into prominence the existence well within areas of cyclonic activity of "dry inversions," the occurrence of which is more commonly associated with the margins of anticyclones.

Experiments on *Ciona intestinalis*.

IT is remarkable that in all the statements that I have seen by Dr. Kammerer or Prof. MacBride concerning the increase in length of the siphons in Ciona following amputation, no measurements are given. As I have recently made measurements on a number of specimens in order to obtain some data indicating the natural variation in the proportional length of the oral siphon, I should be glad if Prof. MacBride would inform us whether Dr. Kammerer has published, or whether he possesses unpublished, any measurements of the siphons in his specimens before and after amputation, and in the offspring which inherited the increased length.

I find it difficult to understand what Prof. MacBride means by the words "the reaction is of the animal as a whole." It may be a fact that amputation of both siphons results in the growth of longer siphons, and of the oral siphon alone in the growth of a siphon of the same length as before, but I do not see how

the "reaction of the animal as a whole" explains the fact.

Prof. MacBride has a photograph of an operated Ciona and a normal one side by side. What is the proportional length of the oral siphon in a "normal" Ciona, and what was that length in the operated siphon before operation and after regeneration?

Mrs. Hertha Ayrton.

IT must be a matter of pain and surprise to many readers of NATURE that Professor Armstrong should have written such an article as that which appears on p. 800 of the issue of December 1.

I was privileged to know, with the intimacy which is only possible to a doctor, both Prof. and Mrs. Ayrton during many years. He was my patient until he died—prematurely in one sense, but in another he lived long, and accomplished more than many men who live to extreme old age. It seems almost sacrilege to speak of their married life, or of the perfect sympathy and companionship which distinguished it; it is difficult to understand how any one professing to have been their friend could suggest that they were "an ill-assorted couple."

No woman could have nursed her husband with more untiring, unselfish, and tender devotion. Of their scientific work I leave others to speak; there will surely be many who will vindicate their memory in this respect. But as an old and intimate friend I am well qualified to protest against the heartless comments upon the private life of a very noble woman of whose living presence we are so recently bereaved. The Latin races respect their dead friends with an emotion we can at least respect. The Day of the Dead, held in reverence probably surpassing anything in the Christian ritual, has scarcely passed this year, and yet Prof. Armstrong can write such an article upon his dead friends. Surely for the rest of his life he will regret not having declined that "appeal" for an obituary notice.

H. H. MILLS.

21 St. Mary Abbot's Terrace,
Kensington, W.14,
December 3.

The only comment I can possibly make on the above is, that the writer must be strangely lacking in sense of humour.

When I used to tell my friends that they were "ill-assorted," knowing this full well and knowing me, they did but smile. As did Mrs. Ayrton—when, to terminate one of our fruitless discussions on the woman as man, I sometimes said: "We will admit you are 'up to us' (apart from being yourselves), when you are regularly engaged as chefs and produce one to go down to posterity with Soyer."

May I here note the need of a correction in my article—the insertion of the accent over the first *e* in Mélisande? So beautiful a name should not be reft of the least shade of its charm.

HENRY E. ARMSTRONG.

Zoological Bibliography.

LEST it should be assumed from my friend Dr. Bather's communication to NATURE of December 1, page 794, that my letter was premature, let me state that my communication was forwarded to NATURE at the express wish of the Conference of Delegates and with the concurrence of the various officers of the British Association, who were present at the time.

There is no misunderstanding whatever as to the wishes of the representatives of the numerous scientific societies present in regard to the size of publications, and if Dr. Bather will consult such a publication as Collins's "Authors' and Printers' Dictionary," issued by the Oxford University Press, he will find that demy-octavo is slightly less than the measurements he gives, namely, $8\frac{3}{4} \times 5\frac{1}{2}$ in., and this is the size which that particular committee recommends to all societies publishing annual reports, etc.

T. SHEPPARD.

The Municipal Museums, Hull.

Micelles and Colloidal Ions.

MR. W. B. HARDY in his letter to NATURE of October 13, p. 537, entitled "The Micelle—A Question of Notation," advocates the conception of the colloidal ion and postulates that the ideas of other workers coincide with his own, so that merely a question of nomenclature is involved; nevertheless, in his opinion, it is positively wrong to refer to a colloidal ion as a micelle.

It will be shown in a paper by Miss M. E. Laing which we hope to publish in an early number of the *Journal of Physical Chemistry*, that all movement in an electric field can be summed up in a single formula which applies equally to ions, diaphragms, gels, suspensions, micelles, etc., and governs the movement of any such charged constituent relative to the solvent. The experimental evidence shows that there is a gradual transition from uncharged or isoelectric colloidal particles, through those which are very slightly charged, such as the neutral micelle in soap solution or the particles in a gold sol, to those which are much more highly charged, like the ionic micelle of soaps, and then to the true ions which are fully charged.

Now comes the question of nomenclature. There is no question as to the fully charged ion where this coincides with the chemical unit. In soap solutions, however, there is a sharp distinction between the behaviour of the single crystalloidal molecules or ions and their respective aggregations, the neutral and ionic micelles, which, for example, can be held back by an ultrafilter.

It would seem as repugnant to designate an aggregate of soap ions containing substantial proportions of undissociated soap and of solvent a "colloidal ion" as it would be to call aggregates of hydrated neutral soap, which are probably the structural basis of soap jellies, "colloidal molecules," although one is as logical as the other. I have called each of these aggregates a micelle, and have described their electrical condition by adding the prefixes neutral and ionic respectively. The term micelle is customarily employed in a similar sense in contemporary French and German science.

The Treatment of Disease by Artificial Light.

PHOTOTHERAPY, or the treatment of disease by light, was first prominently brought to the notice of the medical profession by the work of Finsen in 1895. He demonstrated that the rays of the visible spectrum, and also those invisible radiations which we call ultra-violet rays, have varying therapeutic qualities. He showed that the exclusion of the ultra-violet rays from the skin of patients suffering from smallpox cut short the secondary fever characteristic of this disease, and diminished the suppurative stage, and, thereby, shortened the duration of the illness and lessened the risk of ugly scarring. On the other hand, he proved that the local application of concentrated actinic light had a powerful influence on certain affections of the skin, particularly on the common type of cutaneous tuberculosis known as lupus vulgaris. Before his death he had already appreciated the value of a more general application of light, namely, the exposure of the whole body to radiation.

In his earlier experiments with concentrated light, Finsen used the sun; and a simple apparatus consisting of a large hollow lens containing a blue solution was the means by which the actinic rays of light were brought to a focus upon the skin. Even with a blue medium used as a filter it was found necessary to interpose a cooling apparatus at the focus of the lens. This apparatus consisted of a small circular chamber with quartz faces through which a current of cold water constantly circulated. In addition to its value as a method of preventing excessive heating of the part, this apparatus was also used as a compressor to render the area under treatment bloodless, as it had been found by experiment that the actinic rays penetrated a blanched skin, whereas in that through which the blood was circulating the red colouring matter of the blood prevented the passage of the blue and ultra-violet rays. In Denmark, as in other countries in northern latitudes, the number of days on which the sun could be utilised was so limited that Finsen soon abandoned the sun as an illuminant and substituted powerful electric arc lights.

Following on Finsen's discovery, a number of workers in this field devised other forms of illuminant, and several lamps of high actinic power became available.

It is interesting at this point to consider the work of Rollier at Leysin. For more than twenty years he has been treating cases of tuberculosis, particularly in children, by exposing the surface of the body to the alpine sun, and his efforts have achieved a striking success. At first it was believed that the air of the high altitude was the determining factor in the admirable results obtained, but it has since been shown that it is the light which is the important agent. Rollier's success stimulated others in this branch of phototherapy, and at the Treloar Homes at Alton and Hayling, Hants, Sir Henry Gauvain has shown the practical value of this measure, even in this climate, in the treatment of tuberculous disease of the bones, joints, and skin. More recently, Reyn, in Copenhagen, has shown that the carbon arc light can be used as a substitute for the sun, and that the results of an electric light bath are as efficient as the sun bath.

The treatment of disease by artificial light, therefore, must be considered from two points of view. First, the local application of the radiations to the diseased focus, and second, the application of light to the whole of the surface, which for convenience we may call the "light bath." First, the local application of light to a diseased area; here we find two methods in use, one in which the light is concentrated by means of lenses, and the other in which reliance is placed on the intensity of the actinic radiations, without concentration.

LOCAL TREATMENT BY CONCENTRATED LIGHT.—The typical apparatus for treatment by concentrated actinic light is the Finsen lamp, or its modification the Finsen-Reyn lamp. The essentials in these are a powerful carbon arc with an automatic adjustment to approximate the carbons as they burn away. The light from the arc is focussed through a series of rock-crystal lenses in a tube containing distilled water. The rays are focussed on an area the size of a shilling, and at the focus is placed the combined compressor and cooling apparatus with a cold-water circulation described above. This type of apparatus is used mainly in the treatment of the form of tuberculosis of the skin known as lupus vulgaris. After an hour's application of the concentrated rays an inflammatory reaction occurs in the skin. The inflammation is so acute that a blister forms which may take several days to a couple of weeks to heal. It is interesting that this reaction does not begin till about six hours after the treatment. Repeated applications are usually necessary to destroy the effects of the invasion of the skin by the tubercle bacillus, but in 60 to 70 per cent. a permanent cure is obtained, many of the patients treated having been watched for twenty years.

In the original Finsen apparatus the current used is 70 volts and 50 amperes. It is therefore advisable to use a transformer when the available current has a high voltage, say 240 to 220. The carbons used are: positive, cored, 25 mm. in diameter and 12 inches long; negative, solid, 18 mm. in diameter and of the same length. By this apparatus four patients can be treated simultaneously.

In the Finsen-Reyn lamp the illuminant is of the scissors type, the current employed being 70 volts, 20 amperes. The positive carbons are cored 12 mm., the negative solid 10 mm. in diameter and 8 inches long. These lamps can be worked from the lighting mains, say of 240 volts in series, with appropriate shunts. One patient only at a time is treated with each Finsen-Reyn lamp.

LOCAL TREATMENT BY UNCONCENTRATED LIGHT.—The most convenient type of apparatus for the local treatment of diseased areas of the skin by unconcentrated light is that devised by Kromayer. It consists of a U-shaped envelope of rock crystal containing mercury vapour. This is surrounded by a second envelope with a rock-crystal window. Between the two envelopes, which are fitted in a metal box, cold water circulates, to absorb the heat rays. The window of the apparatus is pressed firmly against the area of skin to be treated, the pressure being of value in rendering the skin bloodless, and thus increasing the penetration of the ultra-violet rays. The apparatus is fixed on a mobile stand, and can be used off any ordinary

direct electric lighting circuit. On a 240 volts circuit the current used is 3·5 amperes with 120 volts across the arc. It will be noted that a water supply is necessary, a circulation of four pints per minute being required.

LIGHT BATH TREATMENT BY THE CARBON ARC LIGHT.—The experience of Reyn of Copenhagen, confirmed by other observers, is that the best illuminant is carbon arc light. The spectrum of the carbon arc more nearly approaches that of the sun than does that of mercury vapour, and in the experience of the London Hospital, this is further increased by the use of carbons with a tungsten paste core, tungsten giving a spectrum of great richness in ultra-violet rays.

The installation is very simple. A large carbon arc lamp, working at 50 amperes and 70 volts, is suspended from the ceiling at three to three and a half feet above the floor. Around this, at a distance of from three to four feet, the patients, nude, are seated on stools. The whole of the body is exposed, first the front and then the back, the sittings being of half an hour's duration at first, and these are gradually increased up to four hours a day. When the front of the body is under treatment the eyes are carefully protected by a thick mask. The tungsten paste cored carbons used are (+) cored, 25 mm., (−) solid, 18 mm., both 12 inches long.

GENERAL TREATMENT BY MERCURY-VAPOUR LAMP.—The apparatus consists of a quartz lamp or "burner" containing mercury vapour, behind which are placed reflectors of various shapes. The lamp is mounted on a stand which permits its being placed at an appropriate height. It is worked off any direct electric current, and is inexpensive to run. The practical life of a "burner" is, in the larger types, about 1000 hours. A very high actinic illumination is obtained. The patient lies or stands while under treatment, usually at a distance of about three feet, but with the larger model supplied by the Hewittic Electric Company, the maximum distance at which a patient is sensible of the radiation is eighteen feet. At the beginning of the treatment the exposures are given to small areas, and both the area and the duration may be gradually increased until the whole of the back or front of the body is exposed for half an hour. An inflammatory reaction, redness, slight vesication with subsequent desquamation, are common, and after a series of exposures, the skin in the majority of patients becomes strongly pigmented. Several of these lamps may be placed in a suitable apartment, the patients being allowed to move about. The mercury-vapour lamp has been used with success in the treatment of tuberculosis of the skin, glands, bones, and joints. Care is required in the dosage, and it is advisable to estimate the intensity of the actinic rays by a chromo-actinometer. This is specially necessary when a new "burner" is installed.

It has been shown that rickets can be prevented in animals fed on a ricket-producing diet if the surface of the body is exposed to the radiations from a mercury-vapour lamp, and there is an important field of usefulness for this form of radiotherapy carried out with due precautions in the treatment of early rickets in children.

CONCLUSION.—The sphere of usefulness of the light bath is being explored in several directions. A committee appointed by the Medical Research Council is studying the biological action of light, and several valuable investigations have been made. Among others it has been demonstrated that the bactericidal power of the blood of animals can be greatly increased by the exposure of the animal to actinic light. Clinical observation shows that there is a remarkable effect upon the metabolism of the human subject; dull, lethargic patients rapidly become bright, cheerful, and active. The body weight increases in many instances. Chronic tuberculous affections of the skin, mucous membranes, bones, and joints heal rapidly. Other chronic processes, such as rheumatoid arthritis, have also been benefited. The value of light in the prevention and treatment of rickets has been noted above. A course of treatment usually lasts three to five months. Patients whose skin pigments well usually do best, but there is no evidence to show that it is the pigmentation which is the curative factor. At present it can only be considered an index. Evidence so far points to the actinic rays producing some possibly chemical change in the blood which gives it greater power to destroy bacteria and their products.

Some Aspects of the Physical Chemistry of Interfaces.[1]

By Prof. F. G. DONNAN, C.B.E., F.R.S.

IN recent years a great deal of attention has been paid by chemists, physicists, and physiologists to the phenomena which occur at the surfaces or interfaces which separate different sorts of matter in bulk. Things could happen in these regions which did not occur in the more homogeneous and uniform regions well inside the volume of matter in bulk. A surface or surface layer represents a sort of thin cross section which can be probed and examined much more readily than any part of the inside bulk. The living organisms of plants and animals are full of surfaces and membranes. What can happen at surfaces is therefore a matter of great importance for the science of living things.

An essential characteristic of the ordering or arraying of molecules and atoms which seems to occur at surfaces may consist in *special orientation*. In the chemical and physical actions occurring in a volume of liquid the bulk of which is large compared with its surface, the molecules or atoms probably move towards each other with every sort of orientation. Should, however, some special orientation be characteristic of interfaces, then it is clear that such interfaces will exhibit new phenomena due to this special sort of arraying. Moreover, if we are dealing with molecules which are ionised into electrically polar constituents, or which, if not actually dissociated, can be treated as electrically bi-polar, it follows that, if orientation occurs at interfaces and surfaces, then electrical double layers and electrical potential differences may be set up at such boundaries.

[1] From the presidential address delivered to Section B (Chemistry) of the British Association at Liverpool on September 14.

The field of force surrounding an attracting molecule may in reality be very "irregular," and may be specially localised around certain active or "polar" groups. Its region of sensible magnitude may be very variable and relatively small compared with molecular dimensions. The chemical constitution of the molecule is now regarded as determining the varying nature of the field of force surrounding it, so that parts of the molecule possessing high "residual chemical affinity" give rise to specially powerful regions of force. In this way the older "physical" theories of cohesion according to central forces with uniform orientation have been to some extent replaced, or at all events supplemented, by "chemical" theories according to which the attractive force-fields are highly localised round active chemical groups and atoms, are relatively minute in range, and can be saturated or "neutralised" by the atoms or groups of neighbouring or juxtaposed molecules.

W. B. Hardy has been the chief pioneer in the development of these newer theories, having been led thereto by his researches on surface tension, surface films, composite liquid surfaces, and static friction and lubrication. If γ_A be the surface tension of a liquid A, γ_B that of another practically immiscible liquid B, and γ_{AB} the interfacial tension at the interface A/B, then the quantity $W = \gamma_A + \gamma_B - \gamma_{AB}$ represents the decrease of free surface energy, and therefore the maximum work gained, when a surface of A is allowed to approach normally and touch a surface of B at constant temperature. Comparing different liquids A with water as a constant liquid B, Hardy has shown that the quantity W is extremely dependent on the chemical constitution of A, and is especially high when A contains the atomic groups characteristic of alcohols, acids, and esters. Thus, for such saturated substances as octane, cyclohexane, CS_2 and CCl_4, the values of W at ordinary room temperature lie between 21 and 24. Compare with these values the following:

(*a*) Introduction of a hydroxyl group:

Octyl alcohol . . .	46
Cyclohexanol . . .	51·4

(*b*) Introduction of a carboxyl group:

n—Caprylic acid . . .	46·4
Oleic acid . . .	44·7

The natural inference from results such as these is that the cohesional forces are essentially chemical in origin and that they depend in large measure on the presence of "active" atoms or groups of atoms, namely, those possessing strong fields of "residual chemical affinity"; in other words, powerful and highly localised stray fields of electrical or electromagnetic force (or of both types). The existence of such atoms or atomic groups is strong presumptive evidence of the unsymmetrical fields of force postulated by Hardy and therefore of the molecular orientation at surfaces.

This question of the orientation of molecules at the surfaces of liquids has been greatly extended in recent years by a detailed study of the extremely thin and invisible films formed by the primary spreading of oily substances on the surface of water. In a continuation and development of the work of Miss Pockels, the late Lord Rayleigh showed many years ago that when olive oil forms one of these invisible films on water there is no fall in surface tension until the surface concentration reaches a certain very small value. He made the highly interesting and important suggestion that this concentration marks the point where there is formed a continuous layer just one molecule thick. In the case of olive oil, he found this critical thickness to be 10^{-7} cm., and concluded that this number represented the order of magnitude of the diameter of a molecule of the oil. This method was greatly developed by Devaux.

Although these researches had firmly established the theory of the formation of a unimolecular surface layer and therefore of the existence of a *new "two-dimensional" phase of matter,* we owe it to I. Langmuir to have made a very important advance by connecting this conception with the ideas of chemically active groups and molecular orientation. Influenced, no doubt, by the ideas of Hardy, Langmuir reasoned that the formation of these primary unimolecular films must be due to the presence of active groups in the molecules, which are attracted inwards towards the water and thus cause the long open chain molecules of the fatty acids to be oriented on the water surface with their long hydrocarbon axes vertical and side by side.

Working by means of the method of Devaux, Langmuir put these ideas to the test of experiment, and determined the internal molecular dimensions of a unimolecular layer. Calculation of the average distance between two adjacent carbon atoms in the three acids gave the value $1{\cdot}4 \times 10^{-8}$ cm. This distance must be of the order of magnitude of the distance between the centres of the carbon atoms in the crystal structure of a diamond, which is now known to be $1{\cdot}52 \times 10^{-8}$ cm.

These regularly oriented and unimolecular surface films on water have been recently investigated in a very detailed and careful manner by N. K. Adam, who has improved the method employed by Devaux and Langmuir. From a closer analysis of the relationship between the force of surface compression and the surface concentration (expressed as area occupied per molecule), he has shown that a distinction must be made between the close packing of the polar or active end groups (head groups) of the molecules and the subsequent close packing of the hydrocarbon chains.

Some interesting results have also been obtained in Sir William Bragg's laboratory by Dr. A. Müller. In these experiments layers of crystallised fatty acids on glass plates have been examined by an X-ray photographic method. From these results it appears that the unit cell is a long prism, the cross section of which remains constant for the substances investigated, whilst the length of the prism increases linearly with the number of carbon atoms in the molecule. The increase in length of the unit prism per carbon atom in the molecule is found to be $2{\cdot}0 \times 10^{-8}$ cm. Since it appears likely that there are *two* molecules arranged along the long axis of each unit cell (prism), it would follow that the increase in the length of the molecule per carbon atom added is $1{\cdot}0 \times 10^{-8}$ cm. Comparing this result with the value for the distance between the carbon centres in the diamond lattice, it would appear that the carbon atoms in the long hydrocarbon chains of the higher saturated fatty acids are arranged in a zig-zag, or more probably in a spiral or helix.

If this be the case, the closer packing or compression of the juxtaposed molecules in the unimolecular films, as revealed in the investigations of Devaux, Langmuir, and Adam, may be to some extent explained by the straightening out of these zig-zags, or perhaps by the "elastic compression" of the helices.

As pointed out by Langmuir, the question of the formation of unimolecular surface films can be attacked in a different manner. It is known that gases or vapours can be condensed or adsorbed by solid and liquid surfaces. The question then arises, does the formation of primary unimolecular films ever occur in such cases? It will be recollected that Hardy made the suggestion that the formation of the primary unimolecular film in the spreading of oily substances on water might be due to adsorption from the vapour. In order to examine this question, Mr. T. Iredale has recently measured in my laboratory the fall in the surface tension of mercury caused by exposing a fresh mercury surface to vapours of increasing partial pressure. The excess surface concentration q of the adsorbed vapour can then be calculated by means of Gibbs's formula

$$q=-\frac{\rho d\gamma}{dp},$$

where γ=surface tension, and ρ and p denote the density and partial pressure of the vapour respectively. Working with the vapour of methyl acetate, Iredale found in this way that at a temperature of 26° C. and a partial pressure of 62 mm. of mercury, $q=4\cdot5\times10^{-8}$ gm. per square centimetre of surface. From this result we can readily calculate that there are $0\cdot37\times10^{15}$ molecules of methyl acetate adsorbed per sq. cm., and that the area per molecule is 27×10^{-16} sq. cm. As under the conditions corresponding to this calculation the molecular surface layer was probably not quite saturated (in the unimolecular sense), we may expect the value found to be of the same order of magnitude but somewhat greater than the values found by Adam for the cross section of the head group of the higher saturated fatty acids (25×10^{-16}) and of the esters (22×10^{-16} for ethyl palmitate and ethyl behenate). We may, therefore, say that Iredale's results appear to indicate the formation of a primary unimolecular layer built up by adsorption from the vapour phase.

Langmuir has measured the adsorption of a number of gases at low temperatures and pressures on measured surfaces of mica and glass, and has arrived at the conclusion that the maximum quantities adsorbed are always somewhat less than the amounts to be expected in a unimolecular surface layer. E. K. Carver, who has measured the adsorption of toluene vapour on known glass surfaces, has arrived at a similar conclusion. The view that the *maximum* adsorption from the gas phase cannot exceed a unimolecular layer has, however, been much criticised.

Let us now consider another type of formation of surface layers at the surfaces of liquids—namely, the case where a substance dissolved in a liquid concentrates preferentially at the liquid-air or liquid-vapour interface. Gibbs, and later J. J. Thomson, have shown that if a dissolved substance (in relatively dilute solution) lowers the surface tension, it will concentrate at the surface. That such a phenomenon actually occurs has been qualitatively demonstrated in the experiments of D. H. Hall, J. von Zawidski, and F. B. Kenrick and C. Benson, by the analysis of foams and froths. In 1908 S. R. Milner used the same method in the case of aqueous solutions of sodium oleate, and arrived at a mean value of $1\cdot2\times10^{-10}$ gram mols. excess concentration per sq. cm. of surface. In the case of dilute solution, we can calculate q, the amount concentrated or "adsorbed" in the surface per sq. cm. (excess surface concentration), and Milner calculated from Whatmough's data for aqueous solutions of acetic acid that the "saturation" value of q is $3\cdot3\times10^{-10}$ mols. per sq. cm., from which it follows that the area per molecule in the surface is 50×10^{-16} sq. cm. In a similar manner, Langmuir has calculated from B. de Szyszkowski's data for aqueous solutions of propionic, butyric, valeric, and caproic acids that the surface area per molecule adsorbed in the saturated layer is equal to 31×10^{-16} sq. cm., while Harkins has arrived from his own measurements for butyric acid at the value 36×10^{-16} sq. cm.

In 1911 Dr. J. T. Barker and I made a direct determination of q for a solution of nonylic acid in water. For a practically saturated surface layer it was found that q was about $1\cdot0\times10^{-7}$ grm. per sq. cm., or $3\cdot1\times10^{14}$ molecules per sq. cm. From this result it follows that the surface area per molecule is 26×10^{-16} sq. cm.

These values are not very different from the values found by Langmuir and by Adam for the oriented unimolecular layers of practically insoluble fatty acids resting on the surface of water. That in the present case some of the values are larger might easily be explained on the ground that these adsorption layers are partially, or completely, in the state of "surface vapours." For Adam and Marcelin have recently made the important discovery that the unimolecular surface films investigated by them may pass rapidly on increase of temperature from the state of "solid" or "liquid" surface films to the state of "vaporised" surface films, in which the juxtaposed molecules become detached from each other and move about with a Brownian or quasi-molecular motion.

It is, indeed, highly probable that the molecules which are concentrated in the surface from the state of solution in the liquid phase are not in quite the same situation as the molecules of practically insoluble substances which are placed *on* the surface. In the former case the molecules are still "dissolved," so that they will be more subject to thermal agitation and less able to form a juxtaposed unimolecular layer. They may also be "hydrated." Nevertheless, the agreement as regards order of magnitude in the values of the surface area per molecule in the two types of case is certainly very suggestive and significant.

Let me now direct attention to another very interesting phenomenon relating to the surfaces of liquids and solutions—namely, the existence of an electrical potential gradient or potential difference (P.D.) in the surface layer. The liquid-gas interface offers the simplest case of such interfaces, so the investigation of the potential differences which may exist at this interface is a matter of fundamental interest. In 1896 F. B. Kenrick developed,

on the basis of earlier experiments of Bichat and Blondlot, an electrometric condenser method for the comparative determination of the gas-liquid P.D.'s. The results which he obtained show that substances (such as the aliphatic alcohols and acids) which concentrate at the surface produce a very great change in the surface P.D., whilst highly dissociated univalent inorganic salts, such as potassium chloride, do not. The results obtained by Kenrick have been much extended by an investigation carried out with the same type of apparatus by Prof. T. Thorwaldson in my laboratory. The general result of these experiments can be described in the following terms:

Consider the system:

Aqueous solution of KCl (conc. $=c$) A	Air	Aqueous solution of KCl (conc. $=c$) B

The positive potential of A will be equal to that of B. If we now add to the solution B a small quantity of a substance S (generally a non-electrolyte or weak electrolyte) which has a strong tendency to concentrate at the air-B interface, it is found that the positive potential of A rises markedly above that of B, the value of the quantity, positive potential of A minus that of B, varying with the concentration of S in the way that is characteristic of adsorption phenomena. What is the interpretation of this phenomenon?

Quincke has shown that a bubble of air in water placed in an electrical potential gradient travels towards the anode—*i.e.* the bubble behaves as if it were negatively charged. From this it would follow that the P.D. at the air-water interface is such that the *negative* half lies towards the air side. As an electrolyte such as potassium chloride is negatively adsorbed at an air-liquid surface, it is probable that a P.D. of the character indicated by Quincke's experiment exists at the A-air interface. If we accept this conclusion, it follows that the effect of S is markedly to *reduce* this P.D. (or to reverse it). Now the P.D. at the air-water interface is probably due to the existence of a double layer containing hydroxyl ions on the outside and hydrogen ions on the inside, or to oriented water molecules regarded as electrical bi-poles. If S is a non-electrolyte (or a substance which possesses little self-ionisation), we can understand why its concentration at the surface could result in the reduction of this P.D.

Within the last few years H. A. McTaggart has made a number of experiments on the electric cataphoresis of gas bubbles in aqueous solutions and other liquids. He finds that aliphatic acids and alcohols in aqueous solution reduce the surface P.D., and that this effect runs parallel with their influence on the surface tension of water. He also finds that acids reduce the P.D. These results may be regarded as a corroboration of those obtained by Kenrick. McTaggart has found that the nitrates of tri- and tetravalent cations have a powerful effect in not only reducing but even reversing the P.D. (*i.e.* the bubble becomes positively charged). His experiments also show that polyvalent negative ions, such as the ferrocyanide ion, act in the opposite direction to the polyvalent cations—*i.e.* they increase the negative charge on the bubble or diminish a previously existing positive one.

The subjects which I have been discussing have an interesting bearing on the formation and stability of foams and froths. If air be violently churned up with water, only comparatively large bubbles are produced, and these quickly rise to the surface and burst. If now a very small quantity of a substance which concentrates at the air-water interface be added, an almost milk-white "air emulsion" of small bubbles is produced, which rise to the surface and produce a relatively durable froth. It is clear that the diminution in interfacial tension facilitates the subdivision or dispersal of the air. The existence of the surface layer will also confer a certain amount of stability on the resultant froth, since it will give rise to forces which resist the thinning of a bubble wall. Any sudden increase in the surface will produce a momentary diminution in the concentration or "thickness" of the surface layer, and hence a rise in surface tension, which will persist until the normal thickness or concentration is readjusted by diffusion of molecules from the inside volume—a process which in very dilute solution will occupy a perceptible time.

(*To be continued.*)

Obituary.

Dr. Alexander Gleichen.

The sudden and unexpected death of Dr. Alexander Gleichen on October 21 is reported from Berlin. Born at Niederschönweide on September 23, 1862, Dr. Gleichen commenced his higher education at the Neu-Ruppiner Academy, and later studied mathematics and natural philosophy at the University of Berlin. After passing his final examination at the University of Kiel, he became an assistant and then a head teacher at the Kaiser-Wilhelm Academy. At the same time he acted as "Privatdozent" at the Technical High School of Charlottenburg, where he lectured upon geometrical optics, a subject with which his name will always be associated. He also lectured upon mathematics at the Helene Lange College for Women.

Dr. Gleichen's academic career terminated in 1904, when he was called to the German Patent Office, with which he was connected until the end of 1918. While thus occupied, he was able to produce the *Archiv für Optik*, and later to act as editor of the scientific and technical sections of the optical and mechanical central journal. From 1919 until his death Dr. Gleichen was engaged in the scientific work of the C. P. Goerz optical establishment, where the opportunity was afforded him of applying his special knowledge of ophthalmic theory to the satisfaction of the ever-increasing demands of the spectacle industry.

Beyond Germany, Dr. Gleichen is best known as a writer of optical text-books of particular value to the student whose object it may be later to apply his knowledge to the practice of the art. This combination of theory and practice is most marked in his "Schule der Optik," published in 1914, and in his "Theorie der modernen optischen Instrumente" of 1911. The latter

book was, in 1918, translated into English under the auspices of the Committee of the Privy Council for Scientific and Industrial Research. The "Schule der Optik" has been translated into Spanish. As a theoretical treatise, his first work, published in 1902 and later translated into French, the "Lehrbuch der geometrischen Optik," is generally regarded as his most valuable legacy to the literature of optics.

The long list of Dr. Gleichen's books and contributions to scientific journals and societies is indicative of a life the leisure hours of which were exclusively applied to the study and expression of the science to which he was devoted; and yet it was characteristic of Dr. Gleichen that he was never too absorbed in his own affairs to appreciate the needs of others and was ever ready to leave his desk to assist a fellow-worker.

JAMES WEIR FRENCH.

MR. G. D. MAYNARD.

THE untimely death of George Darell Maynard at the age of forty-seven has removed another of the small company of medical biometricians which lost Dr. Goring in the pandemic of influenza and Dr. R. J. Ewart this year. Maynard did not enter the field of statistics until he had had wide clinical experience, and at the time of his death he was in active medical practice.

The first notable contribution by Maynard to medical statistics was a paper on anti-typhoid inoculation published in the sixth volume of *Biometrika*, and he contributed four other memoirs to that journal, the last of which was published this year. He was the author of three of the memoirs issued by the South African Institute for Medical Research. The first of these, "An Enquiry into the Etiology, Manifestations, and Prevention of Pneumonia amongst Natives on the Rand recruited from Tropical Areas" (November 1913), is perhaps his most important contribution. Apart from the critical appraisement of the value of inoculation, the section of the memoir which examines the evidence in favour of the view that pneumonia is an infectious disease is a strikingly original piece of work.

Maynard was the first writer to propose statistical criteria of infectiousness, and his treatment of "runs" of cases is very suggestive, while his use of time intervals shows that he had grasped a notion which has since been developed by various mathematical statisticians. The joint memoir (with Dr. G. A. Turner) on "Bantu Natives" (1914) is a careful piece of biometry, and the same may be said of his biometric study of the typanosomes of sleeping sickness (1915). Maynard's work on the correlation of the death-rates from cancer and diabetes (*Biom.* vii. 276) was one of the first applications to the problem of cancer of the calculus of correlations and contains a great deal which is valuable and suggestive. As, except during a brief period, his research work was the product of a scanty leisure, and he never enjoyed access to a first-rate collection of statistical literature, the range and accuracy of his contributions are remarkable. His loss, at the zenith of his powers, is a serious blow to science. M. G.

MR. T. F. CHEESEMAN.

BOTANY in New Zealand has sustained a heavy loss by the death of Mr. Thomas Frederic Cheeseman, Curator of the Auckland Museum. Thomas Kirk had been entrusted with the writing of the "Students' Flora" of New Zealand, but it was cut short by his death in 1897. The half-finished volume being brought out by the Government in 1899, was followed in 1900 by a commission to Mr. Cheeseman to draw up a complete flora of the Dominion, at the same time he was set free from his duties of Curator. He had begun his researches in 1870, embracing the whole region from the Kermadec Islands to Otago. The result appeared in 1906, entitled "Manual of the New Zealand Flora," and is regarded by those who have used it, as one of the best local floras in existence. This volume being completed, its author turned his attention to a series of plates in illustration, selected by Mr. Cheeseman, but drawn and lithographed in England under the care of Mr. W. Botting Hemsley, F.R.S., which were worked and sent to New Zealand, where the text was printed, and the book published at Wellington in two quarto volumes.

At the last anniversary meeting of the Linnean Society, the award was made to Mr. T. F. Cheeseman of the gold medal, its highest award, which was received for him by the High Commissioner. It was a matter of the highest gratification when received, but a few months later, news came that his death had occurred in October last, unexpectedly, though he was known to be far from strong. He had read the proof of his revised "Manual" as far as the end of Monocotyledons.

For years Mr. Cheeseman had worked alone, without a botanical companion, his knowledge being entirely due to reading and observation. He was gifted with extraordinary patience, sound judgment, and calm common sense; gentle and lovable, he had a quiet sense of humour, betrayed by the twinkle in his eye. Mr. Cheeseman, who was born in Hull in 1846, had been a fellow of the Linnean Society since 1873.

B. D. J.

WE regret to announce the following deaths:

Canon T. G. Bonney, F.R.S., emeritus professor of geology in University College, London, on December 10, aged ninety.

Lieut.-Col. H. H. Godwin-Austen, F.R.S., on December 2, aged eighty-nine.

Dr. L. Grunmach, a member of the Physikalisch-Technischen Reichsanstalt, Berlin, and Privatdozent in physics at the Berlin Technical College, on October 23, aged seventy-two.

Prof. J. Harkness, Peter Redpath professor of pure mathematics in McGill University, Montreal, aged fifty-nine.

Col. C. Swinhoe, distinguished by his work in entomology, on December 2, aged eighty-six.

Prof. C. C. O. R. Tigerstedt, professor of physiology in the University of Helsingfors, Finland, author of works on the physiology of the blood circulation, on December 2, aged seventy.

Sir Frederick Treves, Bart., formerly Hunterian professor of anatomy and Wilson professor of pathology at the Royal College of Surgeons, Serjeant Surgeon to King Edward VII. and to the present King, on December 7, aged seventy.

Prof. D. T. Wilson, since 1903 a member of the department of astronomy of the Case School of Applied Science, Cleveland, Ohio, who was known for his work on the perturbations of the minor planets, on October 12, aged sixty-one.

Current Topics and Events.

At a very successful dinner given by the Institute of Chemistry at the Hotel Victoria on Monday, December 10, with Mr. A. Chaston Chapman, the president, in the chair, some notable speeches were made relating to the work of chemists, both in times of war and of peace. The dinner marked the 46th anniversary of the foundation of the Institute, and Mr. Chapman rightly stressed the influence which this body has had in promoting a high standard of knowledge and conduct on behalf of its members, and the services it has rendered to the community. The number of fellows, associates, and registered students now reaches a total of more than 5000, so that the Institute may claim to be of real significance to national progress. Lord Haldane, in proposing the toast of the Institute, referred to some of the developments of industry brought about by the applications of science, and he mentioned particularly the establishment and growth of the Imperial College of Science and Technology as a sign of the changed attitude of British people towards science since the days when we let Hofmann go to Berlin instead of retaining him in Great Britain. To the neglect of the vital necessity of science to national prosperity, and to lack of industrial oversight, must be attributed the loss of the coal-tar industry and its related branches. In the early days of electrical engineering also, we let other nations surpass us in the production of machinery and appliances and the employment of electric power, though we were the first to stake out claims in these fields. Though the relation of science to progressive industry is close and effective, almost no reference was made to it in the speeches and addresses with which we have been overwhelmed in the last few weeks through the General Election. The late Lord Salisbury once lamented that, while the work of the statesman, the politician, the soldier, or the leader of men, however great and however fortunate, is of necessity but transitory—what is accomplished by one man being undone by another—the work of the scientific discoverer or inventor has a permanent place in civilisation. Lord Haldane expressed the hope that, as a result of the Election, Parliament will be more interested in the diffusion of knowledge than Parliaments have been in the past, and we trust that whatever party takes the reins of Government in hand will remember that creative science may be made a most potent means of growth of the manufactures and trade of a modern state.

A lecture on "The Application of Science to the Fishing Industry," delivered by Prof. Stanley Gardiner at the Leeds Fisheries Exhibition in September last, has been printed and distributed. It is, primarily, a good account of the points of contact made between science and the fishing industry, and secondarily, a candid criticism of the trade. The author criticises the trawling gear, the handling of the fish, the methods of preserving the fish and the business enterprise of the trawler owners. There are fish near our coasts, he says, which we do not know how to catch. The "Scotch-branded salt herring" is described as "an appalling product, the world's taste for which has assuredly passed." But in 1913 we exported nearly 9 million cwt. of cured herrings, while we imported only about 900,000 cwt. of all kinds of canned fish, salmon included. The fact is that no way of dealing with the enormous potential catch of herrings is practicable except that of curing in salt. The next kind of cured fish that is condemned is the "Newfoundland air-dried salt cod" (much of which comes from the Scottish north-east coast). It would be as easy, the author says, to pack and export this fish brine-frozen; and doubtless it would, but for the very great difference in cost between the very cheap air-drying and the very expensive brine-freezing, to say nothing of the additional cost of transporting and refrigerating the whole cod. The methods of the canners are criticised; thus the author has "failed to discover any British-canned, smoke-cured haddock"; though these were certainly on the market in 1919. The importance of finding the plankton contents of the water as a guide to the place where to shoot herring nets is urged on the experienced skippers of drifters; but though this is sound enough from a scientific point of view, we are not surprised to learn that practical fishermen are "left cold" by scientific work of this kind. It is doubtful whether such criticism, however friendly, is the best way to persuade fishermen and trawler owners of the helpfulness of scientific research.

At a meeting of the Optical Society, held at the Imperial College of Science and Technology, South Kensington, on Tuesday, November 27, Dr. M. von Rohr, of Jena, delivered the 1923 Thomas Young oration. The date was the 123rd anniversary of the delivery by Thomas Young of his famous Bakerian lecture "On the Mechanism of the Eye." The subject of the oration was "Contributions to the history of the spectacle trade from the earliest times to Thomas Young's appearance." The lecturer divided the subject chronologically into six parts. The first period beginning in the 13th century extends to the invention of printing, about 1448; comparatively few spectacles were then in use. The second period, relating principally to the growth of the South German spectacle factories from about 1450 up to 1620, is much better known. At about the same time Venice must have been another important centre of spectacle manufacture, for in the early days of the telescope (the Dutch form and the terrestrial telescope, both made of single, unachromatised lenses) Venetian craftsmen were supplying these instruments; but of Venetian spectacles proper only some casual hints are ascertainable. In both these centres "near" spectacles (for reading and working only) were made. Notable developments took place in Spain from about 1560 up to 1710: distance-spectacles fastened to the head were worn everywhere, even in the highest circles of Spanish aristocracy, and were introduced to China and Japan by Spanish Jesuits. The chief development between 1640 and 1740 was the production of cheap nose spectacles in Nuremberg. The spectacle grinding optician arose in the 18th century. The

greater accuracy indispensable with achromatic objectives (invented by Chester Moor Hall in 1733 and put on the market by John Dollond after 1758) placed the London spectacle maker proper on a much better footing than his Nuremberg competitor working with bad tools and to a very small degree of accuracy.

Mr. A. Bachellery, the Chief Engineer of the French Midi Railway, read a very interesting paper on the electrification of this railway at a joint meeting of the Institution of Electrical Engineers and the Société des Ingénieurs Civils de France (British Section) on November 22. The Midi Railway of France extends in the southernmost part of that country from the Atlantic Ocean to the Mediterranean along the snow-covered Pyrenees, sending off branch lines up most of the valleys of that chain of mountains. In France the standard type of traction current is direct current at 1500 volts, and the standard type of primary current is three phase at 50 frequency. The electric energy is produced at two hydro-electric stations, in one of which the water has a fall of 2300 ft. The pressure is generated at 60,000 volts, but for long-distance transmission it is converted to 150,000 volts, which is the highest pressure used in Europe at the present time. The economies effected by the use of electric traction are notable. The hydro-electric energy is much cheaper than the corresponding energy obtained from coal. Substantial economies on engine shed and repair shop expenses have been effected by electrification. The steep grade on the Bayonne to Toulouse line which took a steam locomotive 34 minutes to climb is now climbed in 13 minutes. The railway company also finds it very profitable to supply electric energy to villages in the neighbourhood of the transmission lines. It intends to electrify 2000 miles of road. The Paris-Lyons-Mediterranean and the Paris-Orleans companies are also electrifying 3800 miles of line. The latter company is constructing a 300 mile 150,000 volt line from the Dordogne power plants to Paris. It will be seen that main line electric traction is making satisfactory progress in France by standardised methods. The English traction engineers who spoke in the discussion agreed practically with the author's conclusions. We have reasons for believing that, before long, main line electric traction in Great Britain will make considerable advances.

As a result of the fire which followed the great earthquake in Japan on September 1, nearly the whole of the collection, amounting to 700,000 volumes, in the library of the Tokyo Imperial University was destroyed. We are glad that an organised effort is to be made by the British Academy to repair this loss. At a meeting of representatives of learned societies, publishing houses and other bodies concerned with the publication and use of books, held on Monday, December 10, at the Royal Society, with Lord Balfour, as president of the British Academy, in the chair, an executive committee was appointed to organise the collection of works for the restoration of the Library. In a letter to Sir Israel Gollancz, secretary of the British Academy, the president of the Tokyo Imperial University states that most of the works destroyed belong to the domains of literature, philosophy, commerce, statistics, and similar departments of the humanities and social science. The Institutes of Physiology and Pharmacology have also lost nearly all their books, but no reference is made by the president to the position of other science libraries, so that we hope it may be assumed that they have, in the main, escaped damage. The vice-chancellors of British universities have already taken some steps towards the supply of books for the Tokyo Imperial University Library, but the appeal to be made by the British Academy will no doubt reach a much larger circle of sympathisers, and we are sure that all British learned institutions, as well as numerous individuals, will respond generously, in money or suitable literary gifts, to the effort to be made to repair the immense losses which the University has experienced.

During the coming season the work of the British School of Archæology in Egypt at Qau will be continued. In particular, search will be made for the source of the ancient human remains, found last year by Mr. Brunton, which are held to belong to the Palæolithic Age. Further explorations will be carried out in the cemetery in which the oldest Coptic MS. of St. John's Gospel was discovered, and the prehistoric cemeteries to the north will be worked in the hope of further discoveries of the ripple pottery and its associated styles. The papyrus of the Gospel of St. John has now been completely opened, photographed, and mounted. It is not only the oldest Biblical Coptic MS., but it is older than any Greek MS. of the Gospel with the exception of the Vatican MS. It is to be edited as a publication of the School by Sir Herbert Thompson, while the manuscript itself is to be placed in the collection of the British and Foreign Bible Society.

News from the Norwegian expedition in the *Maud*, which is drifting across the Arctic Ocean, has appeared in the *Times*. The reports were sent out by the *Maud's* wireless installation and received by the Spitsbergen Radio station. In March 1923 the *Maud* was in lat. 74° 2′ N., long. 170° 20′ E., and was drifting north-west. In September its position was lat. 76° 16′ N., long. 163° 30′ E., when a long-continued north-west gale set in and drove the ship and pack-ice towards the south, with a result that in the end of October it was in lat. 75° 10′ N., long. 159° 30′ E. The current in that part of the polar basin is reported to be from the north-north-east, thus disposing of the likelihood, which was never strong, of extensive land to the north-east of the De Long islands. The *Maud* would appear to be drifting towards the New Siberia Islands, and if it should succeed in passing to the north of that group, will traverse an interesting and unknown part of Arctic Seas, but there is little prospect of the drift taking her to a high northern latitude. Conditions proved unfavourable for the use of the aeroplane. Throughout the summer, there was much mist and the temperatures were low. The floe offered few safe landing-places. Several trial flights were disappointing, and the last one resulted in serious damage to the aeroplane. Scientific

observations from the ship, especially current measurements, have been continued. Captain Wisting reports the death of Mr. Syvertsen, the ship's engineer.

It is announced in the *British Medical Journal* that the French Minister of Public Instruction has introduced a bill for the purpose of awarding to Madame Curie a pension of 40,000 francs per annum, in recognition of her scientific work. It is proposed that the pension shall be conferred on December 28, the twenty-fifth anniversary of the announcement of the discovery of radium by Madame Curie and her late husband.

The annual Exhibition of Scientific Apparatus organised by the Physical Society of London and the Optical Society will be held at the Imperial College of Science, South Kensington, on Wednesday and Thursday, January 2 and 3. The Councils of these Societies invite members of the Faraday Society to attend the Exhibition. Admission is by ticket only, for which application must be made to the Secretary of the Faraday Society.

A Cotton Research Botanist is required at Lyallpur, Punjab, by the Indian Central Cotton Committee, whose duties will consist of investigations with a view of improving local and American cotton schemes. Candidates should possess high qualifications in cotton-breeding and plant-physiology, and apply, with full particulars of age, education, training, and experience, by, at latest, December 24, to the Secretary to the High Commissioner for India, 42 Grosvenor Gardens, S.W.1.

At the request of the Local Committee arranging the meeting of the British Association at Toronto next year, the Council of the Association has changed the date of the meeting from September to August 6-13. The main party will leave England about July 25; and the excursion tour will be after the meeting instead of before it. The new arrangements will, we believe, be preferred to the old by most of the members who propose to attend the meeting, which is likely to be large and successful, as many members of the American Association also intend to take part in it. The British Association will meet in Southampton in 1925, and has received an invitation from the University and city of Oxford to meet there in 1926, which will in due course be presented to the general committee.

The gold medal of the Royal Scottish Geographical Society has been awarded to Dr. Hugh Robert Mill, and the Livingstone gold medal to Dr. Marion I. Newbiggin, in recognition of their distinguished service in geographical research and exploration. In presenting the medal to Dr. Mill, Lord Salvesen, president of the Society, referred to some outstanding points in Dr. Mill's career. For eighteen years he was chairman of Trustees and Director of the British Rainfall Organisation and editor of "British Rainfall" and *Symons's Meteorological Magazine*, while for seven years he was one of the British representatives to the International Council for the Study of the Sea. He has made noteworthy contributions to geographical research and literature. Referring to Dr. Newbiggin, Lord Salvesen spoke of her services as editor, since 1901, of the *Scottish Geographical Magazine*, and of her many works on biological and geographical subjects.

The first Experimental Report to the Atmospheric Corrosion Committee of the British Non-Ferrous Metals Research Association will be presented and discussed at a meeting of the Faraday Society to be held on December 17, at 8 P.M., in the rooms of the Chemical Society, Burlington House, W.1. The very comprehensive series of field tests and laboratory experiments described in the Report were carried out by Mr. W. H. J. Vernon on behalf of the Committee. Persons interested in the subject desirous of attending the discussion may obtain a ticket of admission from the secretary of the Faraday Society, 10 Essex Street, London, W.C.2.

At one time planters were usually at least part owners of the estates that they cultivated, but now most of them are simply salaried employees of London companies. In the report of a sub-committee appointed by the Incorporated Society of Planters upon salaries, general conditions and terms of service on rubber estates in the Malay Peninsula, etc. (Kuala Lumpur, 1923), the rubber planters of Malaya, a numerous body of Europeans, suggest the restoration of the old rate of pay (reduced during the recent slump), and the granting of leave as in Government service at a definite rate, with free passages home for planter, wife, and children. The climate is trying, leave every few years is needful, and cost of travelling has greatly increased. If the prestige of the white man is not to suffer, and the quality and efficiency of the planters to be kept up, something must be done to improve the present conditions.

A paragraph has recently appeared in the technical press referring to a violent explosion which set fire to and sank the British steamer *Otterburn*. The paragraph stated that the disaster was thought to be due to the explosion of barrels of chlorate of potash. Mr. W. J. U. Woolcock, general manager of the Association of British Chemical Manufacturers, informs us that there appears to have been no chlorate of potash on board the ship, but that there was a parcel of chloride of potassium. The transport of dangerous substances is always a matter of difficulty, and it is particularly undesirable that the difficulties should be added to by blaming unnecessarily what is known to be a dangerous substance.

The Scientific Novelties Exhibition last year in aid of King Edward's Hospital Fund for London, at King's College, Strand, W.C. 2, proved so successful that a similar exhibition has been organised for the approaching Christmas vacation. Demonstrations and experiments illustrating modern scientific discovery and research will be in progress 2-5 P.M. and 6-9 P.M. daily throughout the period when the Exhibition is open, December 29-January 9. In addition, a number of distinguished scientific workers are giving their services as lecturers. Every day there will be four or more lectures; among the subjects dealt with in this way are: tuning forks, Egyptian mummies, flame, acoustics of buildings,

atoms and electrons, muscular exercise, giant and dwarf stars, monkey glands, the Himalaya, astronomical evidence bearing on Einstein's theory, the fuel of the future, and new uses of silica in industry. The full time-table of lectures and tickets in advance can be obtained from the secretary of King Edward's Hospital Fund for London, 7 Walbrook, E.C. The unusually wide scope provided by the lectures and demonstrations in both pure and applied science, and the authority given by the names of the lecturers and those associated with the Exhibition, should prove an attraction which it is to be hoped will be of even greater financial assistance to the hospitals of London than the Exhibition of last year.

November was abnormally cold this year in many parts of England, and in places the month was said to be colder than any previous November on record, a feature perhaps greatly due to the short period of observation. Using the meteorological observations at Greenwich Observatory for the civil day, published by the Registrar-General in his weekly return, and comparing with similar observations available from 1841, it is seen that the month's temperature was not unique. The mean temperature for the month was 38·8°; since 1841 there have been three years, 1851, 1871, and 1879, with a lower mean than November this year; the lowest was 38·0° in 1871. The mean of the maximum or day readings was 44·2°; since 1841 there have been three Novembers with a lower mean maximum, in the years 1871, 1879, and 1919, and the lowest was 43·2° in 1871. The mean of the minimum or night readings was 33·3°; there were also three years, 1851, 1871, and 1910, with a lower mean minimum than this year; the lowest was 32·4° in 1851 and 1910. The lowest shade temperature in November was 22·7° on November 26 and 23·4° on November 8; there have been ten Novembers since 1841 with a lower temperature, but only two with a temperature below 20°; the lowest was 18·3° in 1890. The lowest radiation temperature at Greenwich in November this year was 14·0° on November 12 and 14·1° on November 8; there have only been five Novembers since 1856 with a lower radiation temperature; the lowest was 9·1° in 1908.

A dispatch from the Belgrade correspondent of the *Times* published on December 6 records some interesting discoveries at Doiran and Mitrovitsa. At Doiran, the ruined town situated on the lake of the same name, which formed part of the Bulgar front line in Macedonia during the War, workmen have brought to light large columns of white marble, presumably part of a temple, well-preserved marble tablets with finely carved reliefs of the heads of six Greek gods, a quantity of coins, and a vase so large that two men can stand in it with ease. This last should be comparable with the enormous Græco-Roman vase found on the Struma, which stood in the gardens of the French Military Club at Salonika in the latter years of the War. At Mitrovitsa two Roman graves were found on the site of the old Roman Sirmium, once the metropolis of Illyricum. Of these, one contained the sarcophagus of a girl of 14 years of age. The bust of the girl and her brother are represented in relief. The names in the Latin inscription suggest that the girl was a Pannonian, possibly living under the Emperor Marcus Aurelius in the third century A.D. The sarcophagus had evidently been plundered and contained nothing but the skeletal remains.

Our Astronomical Column.

Recovery of D'Arrest's Comet.—This periodic comet was not seen at the 1917 return, and experienced large perturbations by Jupiter in 1920 (minimum distance from Jupiter 0·50). Two nearly identical computations of the perturbations were made: (i.) by Mr. F. R. Cripps, (ii.) by A. Dubiago and A. Lexin of Kasan. Their respective dates of perihelion were 1923, Sept. 14·12 and Sept. 14·715; the other elements of (ii.) were ω 174° 1·5′, Ω 143° 31·7′, i 18° 3·9′, ϕ 38° 1·1′, μ 534·783″, equinox 1925·0.

In spite of these accurate forecasts, search was vainly made for the comet during July, August, and September. However, on Nov. 10 at 11^h 50^m S.A.S.T., Mr. William Reid, of Rondebosch, Cape Town, well known for his cometary discoveries, found a comet the approximate position of which was R.A. 21^h 30^m, S. Decl. 28° 30′. His description was: "Fairly large, very faint, slightly brighter in middle, no nucleus. It appeared like a faint star-cluster with many stellar points." A position on Dec. 1 at 9^h 21^m G.M.T. was telegraphed: R.A. 22^h 39^m 32^s, S. Decl. 25° 16′.

These positions leave no doubt that the object is D'Arrest's Comet, which has presumably brightened physically since the summer. The date of perihelion deduced from the observations using elements (ii.) is Sept. 15·15 G.M.T. The following ephemeris is for Greenwich midnight:

	R.A.	S. Decl.	log r.	log Δ.
Dec. 16.	23^h 22^m 16^s	21° 36′	0·2304	0·2000
,, 20.	23 32 48	20 33	·2369	·2147
,, 24.	23 43 16	19 29	·2436	·2293
,, 28.	23 53 12	18 24	·2500	·2435
Jan. 1.	0 2 56	17 20	0·2565	0·2576

As the distances from sun and earth are rapidly increasing, the comet is not likely to be seen for long. Its recovery is a matter for great satisfaction, as it was in danger of being permanently lost. The present observations will enable accurate predictions to be made for the next two apparitions; the Jupiter perturbations are small in the revolution now commencing.

Interesting Cepheid Variable.—Señor Comas Sola, of Barcelona, discovered, in April last, an interesting variable star in R.A. 15^h $14{\cdot}2^m$, S. Decl. 8° 11′. Harvard College Observatory Bulletin 791 describes a photographic study of the star, which shows that it is a periodic variable with sharp maxima, the period being approximately 0·369 day. It is a Cepheid of the "cluster" type; the extreme range of magnitudes is from 10·8 to 12·5, which is noted as larger than usual for this type. The Bulletin gives a series of suitable comparison stars for the variable, the magnitudes of which are from 7·8 to 12·8. The galactic co-ordinates are 322° +38°.

Research Items.

JĀBIR IBN HAYYĀN.—In a paper in the Proceedings of the Royal Society of Medicine, 1923, vol. 16 (section of the History of Medicine), p. 46, Mr. E. J. Holmyard has collected the information we possess relating to Jābir ibn Hayyān, the most celebrated chemist of Islam. He appears to have lived during the latter half of the 8th century A.D. His birthplace is unknown, but he lived at Kūfa for at least part of his life, perhaps also at Bagdad. He was a voluminous writer, but most of his works are lost. Mr. Holmyard gives a list of the works of Jābir ibn Hayyān, with ninety-two titles. Whilst primarily a chemist, he wrote also on medicine, geometry, astronomy, philosophy, optics, and poetry, was interested in mysticism, and his writings show that he was a man of fine intelligence. The chemical writings indicate an extensive practical knowledge of the usual chemical operations, which he attempted to explain, and the theory of the composition of metals from sulphur and mercury found in the Latin writings of "Geber." Mr. Holmyard leaves open the difficult question as to the identity of the latter with Jābir ibn Hayyān, but he shows conclusively that the arguments so far adduced to prove the contrary are often incorrect and are wholly inadequate.

PINK AND BLUE FLOWERS.—Dr. W. R. Gelston Atkins has a very interesting contribution to the problem of colour in flowers in a paper upon the pink and blue flowers of the Hydrangea in the Scientific Proceedings of the Royal Dublin Society, vol. 17, pages 201-210. It appears that the pink form is usually found in soils with a P_H of 6 or more. Above P_H 7·5, pink flowers appear to be the rule, while blue flowers predominate in more acid soils. Examination of the flowers shows that difference in colour is not due to a difference in reaction of the flowers themselves, but experiment showed that pink flowers contain far less iron than blue ones. In the more alkaline soils ferric salts are no longer available to the plant, and Dr. Atkins's work seems to give good grounds for thinking that difference in colour of these flowers depends in some way upon the greater availability of the iron to the plants growing in the more acid soils.

PLANT PHYSIOLOGY AND VITALISM.—Prof. Walter Stiles, of Reading, makes a brief contribution from the point of view of the plant physiologist to the discussion in progress in the pages of *Scientia* for November upon the subject of vitalism and mechanism. His main theme appears to be that both morphology and physiology seem to be in agreement at the moment that the most hopeful line of attack upon the problem presented by the form and structure of the organism is along the lines of development. The species may be regarded as a special physico-chemical aggregate of substance which provides a definite range of possibility in the final form and structure of the mature organism, depending upon conditions both external and internal prevailing during its development. Engaged in the task of tracing the connexions between this original species substance, the conditions under which it develops and the structures to which it gives rise, physiology is so far from having solved even its most immediate problems, even in those cases where there is little reason to doubt that greater understanding will show that a physico-chemical explanation is adequate, that it has as yet paid little attention to the more abstract question as to whether a closer acquaintance with the complexity of the living organism will find the machinery of physics and chemistry insufficiently resourceful.

THE PAMIR EARTHQUAKE, 1911.—In a paper recently published in the Quarterly Journal of the Geological Society (vol. 79, 1923, pp. 237-245), Mr. R. D. Oldham urges that the Pamir earthquake of February 18, 1911, was the cause and not, as the late Prince Galitzin considered, the result of the great landslip which occurred at the same time (NATURE, vol. 111, p. 682). The disturbed area of superficial earthquakes, as in the Ischian earthquake of 1883, is always small; that of the Pamir earthquake was more than 200 miles in diameter, while the region of destructive intensity was at least 40 miles in length. The earthquake was followed by after-shocks, and numerous landslips occurred in other parts of the central district. Moreover—and this is the most important point—the great landslip occurred close to the east end of that district. Mr. Oldham thus concludes that the earthquake was of deep-seated origin, though he regards it as possible that the unusual development of the surface waves may have been due in part to the landslip.

COMAGMATIC REGIONS AND WEGENER'S HYPOTHESIS.—Prof. H. S. Washington has completed his studies of the lavas of the Hawaiian Islands by an account of the succession of olivine-basalts in Kilauea, and by a general summary of his analytical results (*Amer. Journ. Sci.*, vol. 206, p. 338, Oct. 1923). The inclusions brought up from the depths are lumps of peridotte and picrite, and nothing whatever has been found to justify Wegener's suggestion that the Pacific volcanoes are built over residual crust-blocks left behind by drifting continents. Prof. Washington directs attention to this point in a paper on "Comagmatic Regions and the Wegener Hypothesis" (Journ. Washington Acad. Sci., vol. 13, p. 339, 1923), and he cites a number of cases in which the igneous rock-types, in districts regarded by Wegener as having been formerly united, differ markedly on opposite sides of the Atlantic. The Triassic plateau-basalts of the later Karroo series resemble those of S. America, from Brazil to Argentina; but such islands as occur in the S. Atlantic contain sodic and not sodic-calcic (basaltic) lavas (p. 346). An example of two identical comagmatic regions, separated by oceanic waters, appears in the description of "The Dolerites of King George Land and Adelie Land," by Dr. W. R. Browne (Australasian Antarctic Exped., Sci. Rep., Ser. A, vol. 3, pt. 3, 1923). The resemblance between the igneous series in Tasmania and that in the region due south of it in Antarctica appears to be complete. Prof. Washington has sought such identity in vain in his study of the opposed coasts of the North Atlantic.

WEATHER OF AUSTRALIA.—A report of the Meteorological Service of the Commonwealth of Australia has just been issued for the year 1921–22 by Mr. H. A. Hunt, the Commonwealth Meteorologist. Like many other meteorological and scientific establishments in different parts of the world, the funds available for the work are not sufficient to allow of desirable and much needed extension. The author has pointed out the direct monetary value derived by the general public and special trades and employments from the

activities of the Weather Bureau and its weather forecasts. There are many industries helped by rainfall, while others are hindered. Weather changes such as heat and cold, fog, hail, and squally conditions are referred to as influencing general trade and journeyings. In confirmation of good work done, reference is made to the death roll of the pearling fleet in Western Australia; the lives lost in 1887 numbered 200, while in 1910 the deaths had decreased to 40. For the improvement of flood and storm warnings as well as the ordinary forecasts for the general public, reports are badly required from more land stations as well as from ships at sea. The Government Meteorologist deplores the want of funds for the purchase of instruments required for observational work. Data are available for aviators, but funds are required for their publication, and tracks of hurricanes and storms in Australia and the neighbouring sea, in the South Pacific, for which data exist, require printing for the guidance of navigators. There are 484 climatological and 5922 rainfall stations distributed throughout the Commonwealth and the immediate neighbourhood. Pilot balloon ascents for upper air research during the year numbered 1049; the observations show great turbulence of the atmosphere in the Melbourne region, owing to Melbourne being situated largely in a basin, almost surrounded by hills.

New Dissecting Microscope.—Messrs. R. and J. Beck, Ltd. (Cornhill, E.C.3), have submitted one of their crescent dissecting microscopes for our inspection. The base consists of a heavy crescent-shaped casting with a central pillar for the lens and end-pieces supporting the hardwood hand-rests and thick glass stage. The lenses, which may be either simple or achromatic, are carried in a swinging arm fitted to a solid rod which moves up and down the central pillar by a rack and pinion for focussing, the milled head actuating this being set at a convenient angle. The range of motion is more than three inches. Below the stage and swinging in gimbals is a mirror, one surface of which is silvered; the other is of opal white glass. The hand-rests are very comfortable and the whole instrument is very stable, so much so that it can be used as a compound microscope by attaching a microscope body to the swinging arm.

Action of Sodium Arsenite on Photographic Plates.—When commercial sodium arsenite is applied to a photographic plate it renders it developable, and so, apparently, produces the same change in it as exposure to light does. Lüppo-Cramer suggests that the change is of the nature of the production of traces of an unstable complex, which provides the necessary starting places for initiating the action of the developer. Mr. Walter Clark of the British Photographic Research Association maintains that this suggestion is wrong and that the evidence which he brings forward in a recent communication (*British Journal of Photography*, November 23) is in favour of his contention that the developable condition is brought about in this case by the action of the arsenite "on material other than silver bromide which is present in or adsorbed on the silver halide grain." Mr. Clark finds that a preliminary treatment with chromic acid "lowers to an enormous degree the sensitivity of a plate to arsenite solution," and argues that the formation of complexes would not be affected by this treatment. He finds that sodium arsenite of the formula $NaAsO_2$ (or NaH_2AsO_3) does not react with silver bromide; he gives the characteristic curve produced by treating the plate with the arsenic solution for increasing times, the equivalent of increasing exposures to light, and other interested details connected with this subject.

Müller X-ray Spectrograph.—The now numerous applications of X-ray spectrometry are provided for in a new X-ray spectrograph designed by Dr. Müller and constructed by Messrs. Adam Hilger, Ltd. (75a Camden Road, N.W.1). The instrument is described in a pamphlet of a scientific quality and accuracy which merit high praise. Dr. Müller's instrument is of simple design, and possesses an accuracy sufficient for the great majority of work. It provides for the oscillation of the crystal by means of a clockwork motor, the normal working conditions being about 40 oscillations per hour through an angle of about 12°. Insulated levelling screws and a protective lead screen are provided. The spectrograph is available for any of the three standard methods. For the Bragg method (single crystal) the slit consists of two brass blocks 26 mm. long, which are clamped at a known distance apart. The plate holder is designed to take plates $4\frac{3}{4}$ in. × $\frac{3}{4}$ in. For the Debye method, a powder holder is mounted in place of the crystal carrier. The slit is replaced by a brass block containing a circular aperture 1 mm. in diameter, which points at the powder holder and fits into an aperture of a circular camera, 6 cm. in diameter, bearing a photographic film. A small further change makes the instrument suitable for taking photographs by Hull's method for powders. The spectrograph should prove very useful to crystallographers for information on lattice structure, to chemists for analysis of materials used as X-ray targets, to metallurgists for the investigation of the crystalline structure of metals and alloys, and to radiologists for measuring X-ray wave-length and composition.

Luminescence of Boron Nitride and Calcium Tungstate.—Under certain conditions of preparation boron nitride lights up when brought into contact with the edge of a flame, and fluoresces in the same spectral region under the action of cathode rays. Herr E. Tiede and Frau H. Tomaschek describe experiments in the *Zeitschrift für Elektrochemie*, July 1, 1923, which show, first, that the methods of preparation which give active material are those which favour the crystallisation of the boron nitride, and second, that an examination of active and inactive material, by the Debye and Scherrer X-ray method, proves that the active material is crystalline, while the inactive is amorphous. The first of these authors and Herr A. Schleede describe experiments with calcium tungstate, very pure specimens of which may give intense blue fluorescence under the action of X-rays, with no trace of phosphorescence afterwards. A minute amount of impurity reduces the fluorescence, and produces phosphorescence, the intensity and period of which is strongly influenced by the nature of the impurity and the method of preparation, as in the case of the sulphide "phosphores." The fluorescence depends on the temperature at which the substance is prepared, no effect being produced with cold preparations, and the intensity increasing up to the highest temperature used, 1100° C. An X-ray examination showed that the active material was crystalline, the interference lines becoming more and more marked as the temperature of preparation was raised. An old specimen, prepared in the cold three years ago, which originally showed no fluorescence, was found to fluoresce strongly, and when submitted to X-ray examination proved to be strongly crystalline.

Loud-speaking Telephones.

The Institution of Electrical Engineers and the Physical Society of London had a joint meeting on November 29—Dr. Alexander Russell, the president of both societies, being in the chair—to discuss the problems connected with "Loud-speakers for Wireless and other Purposes." The meeting aroused extraordinary interest owing to the popularity at the present time of loud-speakers in connexion with broadcast reception, and several hundreds of members were unable to obtain admission into the lecture theatre of the Institution of Electrical Engineers.

Prof. A. O. Rankine discussed the general principles involved in the accurate reproduction of sound by means of a loud-speaker. He pointed out that there has been a sudden great public demand for a good instrument, and that the solutions given have practically all been obtained by the method of trial and error. Stated roughly, the problem is how best to secure that sounds emitted in one place may be a sufficiently faithful copy of sounds emitted in another.

The difficulty of the problem lies in the fact that the reproduced sounds must be of considerable intensity. If we are content with feeble intensity in reproduction there are already available sufficiently good loud-speakers. It appears on theoretical grounds that to procure reproduction absolutely perfect in the physical sense—as distinct from the acoustical—is not feasible owing to the variety of transformations necessary in practice.

There is first the amplification of the electrical fluctuations; in the second place, there is the process whereby the current excites corresponding variations of air pressure; and thirdly, there is the treatment of the aerial vibrations after they have been created. So far as the amplification of the electrical waves is concerned, it is found that the more thermionic amplifiers used the more difficult it is to get exact reproduction. The second question, the transformation of a portion of the electrical energy into sound energy, is a very wide one. It may be transformed by electromagnetic, electrostatic, or thermal means, and each method provides a different field for investigation. Lamb has stated that the simple harmonic type of vibration has the pre-eminent position in mechanics because it is the only type which retains its character absolutely unchanged when it is transmitted from one system to another. We can conclude, therefore, that sounds cannot in general be reproduced with perfect precision. All that can be done is to avoid too great changes in the character of the vibrations. Scientifically it is convenient to dissect these vibrations into their harmonic components.

In aiming at loudness there is a temptation to resort to resonance effects in order to secure it. For example, in the majority of telephone diaphragms there are natural frequencies within the frequencies of the sounds used. The corresponding components therefore get preferential treatment. This can be remedied to a considerable extent by damping the diaphragm, but unfortunately this reduces its general sensitivity. An alternative plan is not to reduce resonance but to confine it to values beyond the upper limit of audibility, or at least as far in that direction as practicable. Another plan is to choose mechanisms of very low natural frequencies, but there are theoretical reasons for considering this method not so desirable.

The method is used, however, in a device perfected by Siemens and Halske. It consists of a strip of thin metal foil suspended between the poles of an electromagnet as in the Einthoven galvanometer. The plane of the foil is parallel to the magnetic field, and the incoming telephonic current flows through the foil. This responds by mechanical movements perpendicular to its plane, and is the equivalent of the ordinary telephonic diagram. Its fundamental natural period is two seconds, and it is said to operate without a horn.

In Prof. Rankine's opinion, horns should, whenever possible, be dispensed with owing to their resonant character. The ideal sound resonator would be spherical in shape and excited in such a way that it imparts to the neighbouring air symmetrical fluctuations of pressure. For speech transmission, all room reflections should be damped out both at the sending and at the receiving stations. A large number of listeners, however, appear to be asking for echo effects. In his opinion, when loud-speakers are used, echoes and reverberations should be eliminated at least at one end. In broadcast opera, where transmission already unavoidably has this effect, the listening room should be draped much in the same way as the transmitting room usually is draped.

Prof. C. L. Fortescue considered that, with properly designed valves, no serious distortion was due to the amplifier. In the later stages of the amplification, however, it is necessary to use valves having a considerable power output.

Mr. E. K. Sandeman gave a valuable demonstration of the relative importance of each frequency region in the audible spectrum. By suitable wave filters he cut off all the vibrations with frequencies less than 500 transmitted to a loud-speaker. He showed that the effect on the intelligibility of the speech transmitted from another room was not appreciable, but the "naturalness" of the speech was notably impaired. When all frequencies greater than 1700 were eliminated by filters, the speech was scarcely intelligible. This might be considered as the lowest limit for commercial speech transmission. He proved that the intelligibility was much the same when all frequencies above 1500 were cut off as when all frequencies below 1500 were cut off. Simple and interesting methods of testing speech transmission were given.

Dr. W. H. Eccles compared the advent of broadcasting news and speeches in the history of the world to the advent of the printing press. Whether for good or ill, it had come to stay. Loud-speakers could be used to broadcast political speeches to very large audiences. He mentioned a case in America where a speaker was plainly audible, by means of these devices, to an audience of 700,000.

Mr. G. A. Sutherland, who discussed "auditorium acoustics and the loud-speaker," pointed out that uniform loudness is associated in practice with the absence of curved walls. Curved walls always produce main and subsidiary foci, and are a menace to good acoustics. More satisfactory hearing is likely to be obtained by distributing an audience into a number of small rooms with a loud-speaker in each than by attempting to accommodate them all in a large hall. The presence of an audience is very effective in reducing reverberation. A sure indication that a room is suffering from excessive reverberation is given when increasing the loudness of the sounds increases the distortion. When a loud-speaker is too rich in higher-pitched notes the presence of a large audience has a corrective effect.

Mr. S. G. Brown gave a successful reproduction, by means of his "Frenophone," of a portion of an opera that was being broadcasted by 2LO, the London Broadcasting Station. This instrument has

a rotating glass disc and a steel-backed cork pad which rests in contact with its surface. The cork is linked to a loud-speaker movement, and a telephone receiver presses on the back of the cork. The frictional drag thus varies and works the device.

Capt. Eckersley exhibited a French loud-speaker which gave very satisfactory reproduction. He said that the solution of the problem depended on the loud-speaker at the receiving station. He stated that if properly magnified the signals transmitted by the London Broadcasting Station would give perfectly satisfactory reproduction of speech and music.

Although the meeting started at 5.30 and went on to 9.45, with an hour interval for dinner, the interest of the audience never seemed to flag. The speakers were unanimous in agreeing that the perfect loud-speaker had still to be invented.

Congress of the French Society of Chemical Industry.

"THE exchange of international thought is the only possible salvation of the world," words used by Thomas Hardy, form the text of two recent articles by John Galsworthy in the *Times*. Something more than an exchange of thought internationally is required—close personal acquaintance and direct exchange of opinion are the real needs. It was with this idea in mind that several of us attended the conference of the Société de Chimie Industrielle in Paris on October 21-26—and the game was more than worth the candle, if only as giving the opportunity of appreciating French *politesse* and their incomparable ability as social entertainers. No more is to be said for them than for ourselves as organisers of an effective gathering of scientific workers: they are as unfortunately subdivided in their interests as we are; as little prepared as we are to overcome the evils of the gross specialisation and narrowness of outlook which to-day retard the progress of science within its own ranks and in public esteem. The conference met at the Conservatoire National des Arts et Métiers in fifteen sections, and in each section the programme was disjointed.

The proceedings were opened by a reception on the Sunday evening at the Hôtel Majestic by the president and his wife, M. and Mme. Paul Kestner, a noted name in French chemical industry, which carries us back to the first sulphuric-acid chambers and the discovery of racemic acid, the foundation upon which Pasteur built his colossal edifice. An exquisite musical and terpsichorean entertainment was provided, in which a most refined sense of proportion and sobriety was displayed.

The session was opened on the Monday morning by the president, supported by the Minister of Commerce. An address was then given by M. Menozzi, director of the Agricultural School at Milan. The intention was to make agriculture the primary subject of the conference. After this some of the sections got to work. In the evening, foreign delegates were entertained at dinner by the "Bienvenue Française"—a society which exists with the object of promoting amicable relations between foreign visitors to Paris and the French; the society appears to owe its success largely to Mme. Juvenel, a lady not only full of energy but also gifted with irresistible charm of manner. The dinner was followed by a most perfect musical entertainment in miniature.

On Tuesday there was more sectioning, and in the afternoon a lecture by Prince Giorno Conti on his boric-acid works. Dr. Herbert Levinstein was the chief morning dish—the heroic and collected reader of a long historical statement of the development of the British dyestuff industry, in a French which all the English-speaking members of the audience—who were in the majority—could understand without difficulty. His courage was much admired.

At the closing meeting, on the Wednesday, Sir John Russell gave an address on the relations between the organisms in the soil and its fertility, lecturing with his accustomed fluency; this was much appreciated. In the evening a great banquet was given at the Hôtel Palais D'Orsay.

Thursday morning was spent in visiting the works of M. Potin, who has large grocery stores in Paris, where the fining of *vin ordinaire* is carried out on a large scale. Then the party proceeded to the chocolate works of M. Menier, on the banks of the Marne, where they were entertained at lunch before inspecting the factory. A more perfectly appointed establishment cannot be conceived. On Friday there was an excursion to Rheims. The cathedral was first visited, under the guidance of his Eminence Cardinal Luçon, a man of wonderful vigour though eighty-four years old. In the course of his address, he most solemnly assured us that the cathedral was never used as a post of observation. The manufacture of champagne was then studied in the vaults of Messrs. Pommery and Greno, after which the party was entertained at lunch by the firm. In the afternoon we were motored across the rolling chalk plain on which Rheims is situate to the Hiedsieck vineyard and the Moulin de Verzenay, whence we could see the whole extent of the great battlefield. Much has been done towards restoring the cathedral; the roof is rebuilt, and Rheims itself is half rebuilt. Cathedral and town are a moving spectacle—stark witness of the brutality and barbarism of the German invaders. With such evidence before one, it is impossible not to understand the bitterness of French feeling—to excuse them almost any action in self-protection. Rheims cathedral will long remain a certain proof that the world can never allow German "civilisation" to be the dominant factor. The French are but asking for honourable treatment—for at least part of that which is due to them; but they can obtain no evidence of their enemy's willingness to fulfil his obligations. M. Vidal, the assistant-secretary for technical education, who presided and spoke with wonderful eloquence and convincing sincerity at the Rheims luncheon, was most definite in his assertion that France was entirely pacific in intentions; and the same assurance came from other prominent speakers during the week.

Whatever the value of the meeting in technical respects, socially it was a very great success, and we left it wiser men. French was spoken in many styles, and not a few of our hosts showed themselves to be masters of English; still, the need to cultivate a knowledge of each other's language was ever before us. To think internationally we must understand one another better; true understanding is greatly helped by meetings such as that now described, and it should be regarded as the duty of scientific workers to avail themselves of these opportunities. It is significant that we have a Galsworthy telling us that the future is with science, not to destroy but to save. We need to be up and doing. The public will not come to us, the Press is not with us; it is for us to go forward. The French

are clearly a people of wonderful courage and energy; they are constructive; they are willing to be governed and have a government; the whole nation is at work. The downfall of Germany is due to the destruction of its government: only the appearance of a Bismarck can save it. We may well take warning. We seem to show no constructive power; the politicians are at fault, without imagination, without outlook; our moral attitude towards work, in all classes, is unsound. Unless our science can be made effective we shall soon be nowhere.

HENRY E. ARMSTRONG.

The Present Position of the Ergot Problem.

AMONG well-known drugs, ergot has always occupied a peculiar position. A parasitic fungus, which after many disastrous epidemics was recognised as a scourge, ultimately became the chief medicament of the obstetrician. The numerous attempts of the nineteenth century to isolate its active constituents now appear of little value, but the fundamental discovery by Tanret in 1875 of the crystalline alkaloid ergotinine, $C_{35}H_{39}O_5N_5$, still stands out. Unfortunately this substance does not produce the characteristic effects of ergot to any considerable extent; much later a second alkaloid, ergotoxine, $C_{35}H_{41}O_6N_5$, discovered simultaneously by Barger and Carr in Great Britain, and by Kraft in Switzerland, was, however, found by Dale to have a powerful physiological action, and to produce, for example, the characteristic gangrene. The subsequent discovery, by Barger and Dale, of small amounts of powerfully active, non-specific amines in ergot extracts led some clinicians, particularly in Germany, to substitute these amines for ergot, and to neglect the specific alkaloids.

Attention has been recently again focussed on the latter by A. Stoll, of Basle, who gives in *Die Naturwissenschaften* for August 17 and 24 a résumé of earlier researches and of his own work. In certain varieties of ergot Stoll has discovered two new crystalline alkaloids of the formula $C_{33}H_{35}O_5N_5$. One of these, ergotamine, was found by Spiro to resemble ergotoxine in action, and more recently Dale and Spiro, in a joint paper, declared ergotamine and ergotoxine to be pharmacologically identical. There are therefore no complications on the biological side. Ergotamine can be converted into a less soluble and less potent isomer ergotaminine, which in some respects is analogous to Tanret's ergotinine. Stoll has thus discovered a new pair of alkaloids, showing great similarity to the older pair. The physiologically potent member of each pair has the same action, a finding which, according to Stoll, also results from unpublished experiments of Rothlin. Chemically the new pair are also closely related to the old, by colour reactions, decomposition products, optical rotation, etc. Ergotamine and ergotaminine both differ from ergotinine by C_2H_4, and from ergotoxine by C_2H_6O, the elements of a molecule of ethyl alcohol.

Yet all attempts to convert one pair of alkaloids into the other pair have failed, and for the present they may be regarded as homologues. From some specimens of ergot Stoll obtained only ergotamine, from others only ergotoxine; sometimes both alkaloids were isolated. Yet the identity of the action of these two alkaloids is remarkable, and without parallel among homologues. Are they perhaps both formed from a common precursor by the different methods of extraction employed? Are they perhaps converted into the same active substance in the body? Their puzzling relationship certainly deserves further investigation, which is, however, rendered difficult by the scarcity of suitable material, greatly accentuated by the War.

This seems to be the present position of the ergot question. The résumé under review deals in a useful manner with the older work, and shows how during the last two decades our knowledge of the active principles of ergot has been placed on a solid foundation, largely through English and Swiss work. Most of the investigations of the last century the writer dismisses as valueless. His own important contributions are of the kind we might expect from one who was associated with Willstätter in the study of chlorophyll.

Clothes Moths and their Control.[1]

AMONG entomologists there are well known to be two very common moths the larvæ of which are destructive to fabrics; namely, the case-making clothes moth (*Tinea pellionella* L.) and the webbing clothes moth (*Tineola biselliela* Hum.); the tapestry moth (*Trichophaga tapetzella* L.) is much less frequent but is occasionally destructive. In the case-making clothes moth, the larva makes a portable habitation out of its silk, together with fragments of the material upon which it feeds. It withdraws completely into the case when resting, but when feeding or moving it protrudes its head and foremost body-segments. Pupation also takes place within the case, which is sealed up and anchored to the fabric or other object. The webbing clothes moth is the most abundant species of the three; its larva does not construct a portable case, but spins silken tunnels wherever it crawls over the material which it is consuming. When fully fed it constructs a silken cocoon intermixed with particles of fabric and excrement; this pupal shelter, therefore, is quite different from that of the species previously mentioned. In the rarer tapestry moth the larva constructs silk-lined burrows through the substance of the material which it infests.

In general, the larvæ of clothes moths feed upon wool, fur, feathers, hair, and all fabrics manufactured from them. It will therefore be realised that they may be found attacking not only clothing but also carpets, rugs, furs, upholsteries, stuffed animals, brushes, felts in pianos, and the like. The moths are relatively short-lived; they take no nourishment and are in themselves harmless. Their eggs are laid upon or between folds of fabrics or within the meshes of the latter. They are readily crushed by brushing, etc., and are very fragile. Under average indoor conditions they hatch in about a week, this period being subject to lengthening or shortening according to temperature. The larvæ are relatively long-lived and require from about fifteen weeks to two years to complete their development. Much depends upon the nature of the material upon which they are feeding and the temperature conditions under which they exist. The pupal, or resting, period varies from about eight days in warm summer weather to a month or more in winter. In the British Isles the moths are commonest between June and October, and their larvæ are feeding the great part of the remainder of the annual cycle.

Methods of dealing with these pests are numerous. Fabrics that are well brushed or beaten every two weeks are seldom seriously affected: exposure to

[1] Clothes Moths and their Control, by E. A. Back. U.S. Dept. of Agric. Farmer's Bull. 1353, July 1923. 28 pp. with 21 figs.

direct sunlight is also a valuable measure. Articles of clothing that require to be stored are immune from attack if sealed down in paper bags, or very securely wrapped in several layers of quite unbroken newspaper. Naphthalene, in the form of flakes or balls, should be placed among the clothing thus fastened up. It also acts as a deterrent when placed in drawers or cupboards, but is not entirely effective under such conditions. Paradichlorobenzene appears to be as valuable as naphthalene, but camphor is decidedly less effective.

On a large scale, the cold storage of furs, carpets, and furniture is the most certain of all preventives, and this method is coming more and more into use. Extensive infection of carpets, upholsteries, etc. in large houses, hotels, etc. may need fumigation in order to eradicate clothes moths completely. An effective remedy, which is also non-injurious to furniture, fabrics, plate, or other household goods, is the application of hydrocyanic acid gas. Its manipulation requires the services of an intelligent person who understands the dangers of its use and knows how to administer it. Carbon tetrachloride is also effective, and has the advantage over hydrocyanic acid gas in being neither explosive nor inflammable. Fumigation with sulphur is a well-known remedy, but there is some danger from fire in its application, while it has a bleaching effect on many delicate fabrics, wallpaper, etc., besides tarnishing metals. Carbon disulphide is also recommended, but its vapour is inflammable. Dry heat is now recognised as an effective agent in killing insects. All fabrics will be freed from pests in a very short time if exposed to a temperature of 130° F. Lower temperatures have been found effective against clothes moth larvæ; the latter when exposed in an incubator at 128°, 120°, and 110° F. died in 6, 11, and 31 minutes respectively. Fabrics dipped in water heated to 140° F. will be found to contain no living eggs or larvæ of clothes moths.

It may also be mentioned that there are a number of worthless remedies against these insects, including powdered sulphur, hellebore, and borax; also lavender flowers, cayenne pepper, reasonable strengths of tobacco powder, and other substances are of no value in keeping away these insects. A. D. Imms.

Science in Agriculture.

The somewhat belated appearance of the annual report of the Rothamsted Experimental Station for the year 1921–22 does not deprive it of the perennial interest which must always attach to the doings of this institution. For historically, Rothamsted can claim to be almost the earliest example of the benefits that result from the application of science to industry. From the economic point of view, the discoveries of Lawes and Gilbert take a very high rank in the history of scientific achievement. The most remarkable feature of the early work of Rothamsted was the success with which field and laboratory work were combined. With the ever-growing complexity of all regions of knowledge, it has become increasingly difficult to maintain this tradition. The refinements (the application of statistical methods may be instanced) which modern field research demands, and the revolution in many of the fundamental conceptions of science, are two factors. On the applied side, another obstacle is the smaller apparent margin for improvement in the practice of modern husbandry. Whereas the discoveries of the early workers were productive of changes in farm practice of the order, in terms of economic results, of 100 per cent., in these days, improvements are only possible to the extent, as it were, of 10 per cent.

A recognition of this fact is implied in the statement contained in the report that "the most important development of recent years has been the reorganisation of the work of the Station so as to bring it into touch with modern conditions of agriculture on one side and of science on the other: it is hoped to reorganise in the near future the farm and field work and to improve the field technique." It unquestionably adds to the difficulties of this reorganisation that it should coincide with a period when the whole economic basis of arable farming is so precarious as it is to-day. It is being openly said that arable farming, and particularly the growing of cereals, cannot be made to pay in present circumstances.

In dealing with the finance of the farm attached to the Station, the report states that "from 1920 onwards, the financial results are deplorable, and they show clearly why many of the arable farmers to-day are in their present position." The report does not specifically indicate the most promising line of investigation calculated to remedy this disastrous state of affairs, but there can be little doubt that the Department of Soil Physics, of which the assistant director, Dr. B. A. Keen, is the head, and to which precedence is given in the report, should be so regarded. Under the heading, "The Cultivation of the Soil," some account is given of investigations which promise to yield results which may indicate to the farmer methods by which the cost of cultivation can be reduced, and "costs of cultivation dominate the future of arable farming." In this connexion it may be significant that the American farmer apparently has been able to grow wheat at a profit with a yield of 16 bushels to the acre, whereas the British farmer with a return of 32 bushels is losing money. It is a reasonable deduction that it pays better to reduce the costs of cultivation than to aim at maximum production. In other words, the British farmer may still be paying court to methods the chief recommendation of which is their superior artistry.

In the section headed "The Feeding of the Plant," it is interesting to learn that "broad beans die prematurely unless they receive a homeopathic dose of boric acid in addition to the so-called 'complete' plant food." It is remarkable that a discovery parallel to that of the rôle of accessory food factors in animal nutrition should have been made in relation to plants.

The volume of purely scientific work done at Rothamsted would appear to be considerably greater than that carried on in relation to so-called applied science. As many as fifty-two scientific papers were published during the year by members of the staff. Of these, two were of Royal Society rank, namely:—"The Mathematical Foundations of Theoretical Statistics" (R. A. Fisher), and "A Quantitative Investigation of the Bacterial and Protozoal Population of the Soil" (D. W. Cutler, L. M. Crump, and H. Sandon).

The financial support which the Station now receives from the State is considerable. For the year under notice grants from the Development Fund totalling 22,030*l*. were received. In 1912 the total was approximately 3000*l*. It must be a source of gratification to the director, Sir John Russell, that so great an expansion should have taken place during his term of office.

The Quantum Equivalent in Photo-electric Conduction.

If light of frequency ν is sent through a cold gas which does not absorb it, sensitised by admixture of a second gas which can absorb the light; and the pressure is such that the mean time between two collisions is of the same order of magnitude as the mean life of the excited state of the gas; all those spectral lines of the non-absorbing gas appear which have a smaller excitation energy than $h\nu$. On the other hand, those which require more energy than this are not seen. Results with mixtures of mercury and thorium vapours, and of mercury and silver vapours, using the light of the 2536·7 Å Hg line, agree, on the whole, closely with the above statement. The method can also be used in fixing the series relations between the lines of an element, since it allows us to determine which spectral lines can be excited by an amount of energy smaller than a given amount. Results have been obtained at Göttingen for lead and bismuth, which will shortly be published.

In a paper in the *Zeitschrift für Physik*, 17-3, August 23, p. 202, Messrs. G. Carlo and J. Franck consider the theory more closely, and describe experiments which agree with their conclusions. The sensitising gas A has, as the longest wave of its absorption series, a line of frequency ν, while the corresponding line of the fluorescing gas has the frequency ν_1. Suppose $h\nu : h\nu_1 :: 1 : \frac{3}{4}$; then if light of frequency ν is used, both ν and ν_1 will appear. The elementary act of transmission of energy from an excited atom of A to an atom of B will take place in such a way that $\frac{1}{4}h\nu$ is converted into energy of translation of the colliding atoms. If the temperature is so low that the kinetic energy of temperature movement is small, compared with $h\nu$, the atom receives, besides its excitation energy, the kinetic energy $\frac{1}{2}m_1v_1^2 = \frac{h\nu}{4} \times \frac{1}{1+m_1/m}$. This abnormal velocity of the excited atom of B produces a Doppler effect; the effective frequency is $\nu_2 = \nu_1(1 + \cos\phi v_1/c)$, and this is not absorbed by the other practically resting atoms of B.

An experiment with sodium vapour, sensitised with pure argon, has verified the theory. Sodium vapour can be made to fluoresce by means of the zinc line, 3303 Å, and the sodium can also be excited directly by the D line. Conditions were so adjusted that the tube appeared equally bright with either of these sources, and the light from the fluorescing sodium, in each case, was passed through an absorption tube, containing sodium at a suitable temperature. The light excited by the D line was completely extinguished, while that obtained with the zinc line was much less weakened.

If, in a second experiment, light of frequency ν_1 passes through the mixture of gases A and B, an emission of ν from A can result only if the temperature of the gas is so high that the energy difference $h\nu/4$, which is lacking for the excitation of A, can be obtained on collision from the kinetic energy of the atoms. Experiments have been made with thallium and mercury, and with cadmium and mercury, using the Hg line 2536·7 Å. The quartz vessel containing the vapours was placed in an electric oven, which could be raised to 800° C.; and strong fluorescence was obtained with thallium. In this case it was possible that a thallium line, the excitation energy of which amounts to 5·5 volts, while the energy of 2536·7 Å corresponds to 4·9 volts only, was due to a double or step-by-step process of excitation. At 800° C. part of the atoms are no longer in the normal state; and apparently there is a 1 volt excitation step, from which, up to the 5·5 volts stage, only 4·5 volts would be required, or more than for 2536·7 Å.

With cadmium and mercury this difficulty does not arise, and the confirmation of the theory is direct. It is possible, however, to draw conclusions from the relative intensity of the lines in the fluorescent spectrum of thallium, as compared with the ordinary spectrum of this substance. The differences are ascribed to the differences in absorption, due to the presence or absence of the Doppler effect previously described; and the combined results of the two experiments seem to prove, conclusively, that quantum energy and translation energy can work together, as an elementary act, to produce excitation of the atom.

Early Methods of Oil Painting.[1]

By Prof. A. P. Laurie.

It is evident both from the manuscript of Theophilus and the manuscript of Eraclius that the properties of such drying oils as linseed oil and walnut oil were thoroughly understood as early as the 12th century, if not earlier.

The methods used in their preparation differ very little from the best practice of to-day. The refining and bleaching of the oil and the use of driers was well understood, nor is there any indication, in passing from those earlier recipes to those of the 15th century, that any new discovery of importance was made at the time of the brothers Van Eyck. Passing to later times, Vasari directs that pigments are to be ground in walnut oil or linseed oil, and this is all that is necessary; he recommends the use of walnut oil as less liable to darken with time.

Many recipes for varnishes are given, and, as neither spirit of turpentine nor alcohol was available in commercial quantities until the end of the 15th century, these varnishes are what we should now describe as oil varnishes, consisting of resins dissolved in hot oil. The natural balsams of the pine, resin, mastic, and sandarac, often all mixed together, were used in the preparation of these varnishes. The proportion of resinous material to oil being very high, the varnishes were consequently very sticky and had to be heated and rubbed on with the hand. Spirit varnishes corresponding to the mastic varnishes of to-day are found in 16th century and later recipes.

The evidence of the accounts preserved at Ely and Westminster show that both oil and varnish were used in painting on walls during the 13th and 14th centuries, this being the northern tradition, while the Italian tradition was the use of egg as a medium. There is no indication in these recipes of any special secret differing from what we know to-day.

These early pictures were painted on a wood panel sometimes covered with strips of linen and coated with a gesso made of parchment size and whitening or plaster of Paris which had been soaked in water until it lost its binding properties. Recent experiments carried out by Mr. Thompson at the Heriot-Watt College, Edinburgh, on an old 16th century panel have revealed the fact that this panel was coated with a non-absorbent gesso upon which a very thin layer of absorbent gesso was laid so as to ensure the binding of the oil to the surface of the gesso and, at the same time, to preserve from staining the pure white surface

[1] Synopsis of lecture delivered at the Royal Academy of Arts, London, on Wednesday, November 14.

of the gesso below. On this pure white gesso panel the picture was drawn in detail and laid out either in monochrome or partly in colour with pigments probably mixed with size. Upon this were laid the pigments ground in oil, or it may be an emulsion of varnish and egg, care being taken to paint the high lights very thinly as compared with the rest of the picture. In course of time the oil yellows and the pigments, more especially the white lead, get more translucent. By painting the picture in this way the artist ensures that the increased translucency of his white lead will correct the yellowing of the oil owing to the white light being reflected from the gesso, and that his contrast of light and shade will be maintained.

There is much more yet to be discovered as to these early methods, and the question as to whether varnish, emulsion, or oil was used, has still to be finally cleared up, but our knowledge of the general methods of procedure is growing.

The Geological Society of China.

THE Geological Society of China is one of the scientific institutions founded since the establishment of the Chinese Republic in 1911. The first two Bulletins of the Society promise well for its future. One of the first papers deals with the history of geology in China, which it carries back to early times; but it shows that independent Chinese work on the subject on scientific lines dates from 1911, when V. K. Ting and H. T. Chang returned to China from their western studies. Mr. Chang, the first president of the Society, organised a department and school of geology under the Ministry of Commerce at Nanking in 1912. The Geological Survey of China was established in 1916 with Mr. Ting as its director, and he also secured in 1918 the reopening of Mr. Chang's geological school, which had been discontinued in 1916. To Messrs. Ting and Chang is due the establishment of the promising school of Chinese geology. They have been aided by Mr. Lee, a Chinese student who was trained at Birmingham, Prof. Grabau, the well-known American palæontologist, now professor at Pekin, and Dr. Gunnar Andersson, formerly head of the Geological Survey of Sweden, and now mining advisor to the Chinese Government and director of the Geological Survey Museum.

The two Bulletins contain a valuable series of contributions to the geology of China. They include a lecture given to the Society by Prof. Berkey, of Columbia University, New York, on "the New Petrography," which attaches most importance to the mode of origin of rocks; Prof. Berkey proposes a plethora of new names such as reactionite, saturite, evaporite, disintegrationite, and recrystallisationite. The new petrology must be vigorous to sustain such a nomenclature. The section of this paper of most interest is its expression of the reaction in America against the ingenious quantitative arrangement of rocks which is often known as "the American classification." Prof. Berkey represents that classification as mechanical and misleading, and sets it aside as only a side issue in real petrology.

Prof. Grabau contributes three papers, of which the longest is on the Sinian system; he protests against the modified use of that term proposed by Prof. Bailey Willis, who, with the temporary agreement of von Richthofen, interpreted Sinian as Lower Palæozoic. Von Richthofen, however, appears soon to have gone back from that modification of his term. Prof. Grabau justly holds that the term is in that sense useless, and he applies it to the sedimentary formations in China of pre-Cambrian age. In that sense it is equivalent to the Toridonian, which, as well as the Sinian, Prof. Grabau includes in the Palæozoic.

Mr. Wong contributes a short note upon Chinese earthquakes and on the distribution of the chief seismic centres. The red beds in China are discussed in three papers. Mr. Wong shows that those in Shansi belong to two horizons, one pre-Jurassic and the other later than the Jurassic Coal Measures. Mr. Hsieh shows that in Kansu these deposits range from the Jurassic to the Kainozoic. Mr. Tan describes a marine red series of Eocene age as widely developed in Shantung, and its discovery is one of the most interesting recent additions to Chinese geology.

Three papers by students of the University of Pekin on observations during an excursion to the Nankou district add materially to the knowledge of that now classical section. Prof. Grabau describes from their collections three new species of Collenia, which he explains are based only on the external characters; in the absence of microscopic evidence it must be quite doubtful whether these supposed calcareous algæ are of organic origin. Prof. G. B. Barbour, of the Pei-yang University, Tientsin, describes an intrusive sill in Shantung which, according to his interpretation, shows the effect of gravitational differentiation. The intrusion is pre-Cretaceous, and the later folding and faulting in this region are now definitely identified as Oligocene or Miocene, as the movements are later than the newly discovered Eocene deposits and earlier than the Pliocene.

The two volumes are in English, with a title-page and contents and a summary of one paper in Chinese. Chinese characters are given of the personal names. The titles of some papers which are to be published in future bulletins suggest that the interest of this serial will be well maintained.

J. W. GREGORY.

University and Educational Intelligence.

ABERDEEN.—The Senatus Academicus has awarded the following research scholarships: Fullerton scholarship in science to Mr. Charles Bisset; Robbie scholarship in chemistry to Miss Margaret F. Aitken.

A mural tablet in memory of the late Prof. James W. H. Trail, F.R.S., professor of botany in the University from 1877 until his death in 1919, has been placed in the classroom of the new Department of Botany, and was unveiled and presented to the University, on behalf of the subscribers, by Sir David Prain, on Friday, December 7. The tablet is mounted on a slab of slate. A portrait plaque in dull green bronze is surrounded by a wreath of oak leaves, acorns, and galls. It is flanked by two Brazilian palms, and a decorative panel shows other natural objects representing the varied interests of Prof. Trail. The tablet is the work of Miss Alice B. Woodward. The subscribers have also issued a memorial volume which, besides biographical and bibliographical matter, includes the "Flora of the City Parish of Aberdeen," a comparative and historical work of great detail which had occupied Prof. Trail for many years, and had been completed shortly before his death.

CAMBRIDGE.—A fellowship has been founded at Christ's College by Mr. J. Pierpont Morgan, a member of the College. This is the first addition to the number of fellowships in the College since 1682, and represents a valuable endowment all too rare in these modern times.

The Empire Cotton Growing Corporation has offered to the University a sum of 1000*l.* a year for five years to be devoted to the Plant Genetics Depart-

ment of the School of Agriculture, in accordance with a scheme that has been agreed upon by the Corporation and the Director of the Plant Breeding Research Institute.

Prof. C. E. Inglis, Prof. B. M. Jones, and Prof. G. I. Taylor have been appointed as members of a committee to make recommendations to the Trustees of the Edward Busk Studentship in Aeronautics.

Mr. E. G. D. Murray, research bacteriologist to the Medical Research Council and formerly on the staff of the War Office Central Cerebro-spinal Fever Laboratory, has been elected to a fellowship at Christ's College.

LIVERPOOL.—Applications are invited for the Campbell Brown chair of industrial chemistry. The person appointed will be required to devote his time to research work, with a certain amount of advanced teaching on the chemistry of oils, fats, and waxes other than mineral. Applications must reach the Registrar of the University before March 1 next.

LONDON.—Applications are invited for the Quain professorship of physics, tenable at University College, in succession to Sir William Bragg. They should reach the Academic Registrar, University of London, South Kensington, S.W.7, by, at latest, January 3. Applications are also invited for the University readership in statistics at the London School of Economics. The latest day for the receipt of applications by the Academic Registrar of the University is January 4.

ST. ANDREWS.—An interesting experiment is to be tried in the institution by the University Court of a series of courses of lectures to be held in University College, Dundee, for the convenience of the managing and clerical staff of the L. and N.E. Railway or of other railways. The first course to be carried out is that in railway law, Mr. James Allison having been appointed lecturer. It is intended later to hold courses in railway economics, railway geography, and railway operating.

THE following have been elected as representatives of the Universities in Parliament :—Cambridge : Sir Geoffrey Butler (U.) and Mr. J. F. P. Rawlinson (U.) ; London : Sir S. Russell-Wells (U.) ; Combined English (Birmingham, Bristol, Durham, Leeds, Liverpool, Manchester, and Sheffield) : Sir Martin Conway (U.) and Mr. H. A. L. Fisher (L.) ; Combined Universities of St. Andrews, Glasgow, Aberdeen, and Edinburgh : Rt. Hon. Sir H. Craik (C.), Sir G. Berry (C.), and Mr. D. M. Cowan (L.) ; Queen's University, Belfast : Col. T. Sinclair (U.).

THE Bradford Technical College may shortly become a constituent college of the University of Leeds. It originated in weaving and designing classes at the Bradford Mechanics' Institute in 1877. The main building, finished in 1882, includes lecture rooms and laboratories of departments of chemistry, dyeing, engineering, architecture and building, biology, mathematics, and physics. A textile block, opened in 1911, includes a practical dye-house, finishing shed, special dyeing research laboratory, and a power house specially arranged for demonstration and experimental purposes. Since 1920 there have been added a new engineering block, specially equipped for advanced work and research on internal combustion engines, and union buildings with refectory and common rooms and athletic grounds.

THE provision of ten post-graduate scholarships for the session 1924–25 for overseas students at the Imperial College of Science and Technology, South Kensington, has been announced. Lord Buckmaster, chairman of the governing body of the College, made the offer to the Secretary of State for the Colonies on behalf of "private friends" inspired by the great purpose and opportunity of the College, the only educational institution in Great Britain on the governing body of which are representatives of the Dominions and India, and it has been accepted. The scholarships will be each of the value of 300*l*., and two will be available for university students of each of the Dominions of Canada, Australia, New Zealand, South Africa, and of India. No conditions have been laid down as to the selection of scholars, this being left entirely in the hands of the Prime Ministers of the Dominions and of the Government of India.

CONTACT between the Secondary School and the community it serves is, according to the report of the West Riding Education Committee for 1922–23, conspicuous by its absence, the prevailing local opinion being that these schools are primarily, if not entirely, intended to produce teachers—this, notwithstanding that in fact less than 20 per cent. of the pupils enter the teaching profession and notwithstanding the efforts made to secure recognition by employers of the "First" and "Second" examinations. In connexion with these efforts some headmasters have, says the report, interviewed local chambers of commerce and have modified their school curricula in the light of information thus gained, in order to bring it into closer relation to local industries. The committee recently permitted its inspector in charge of secondary education to visit the United States for the purpose of studying American schools. In that country much attention has, of late, been devoted to promoting co-operation between the school and the local industries.

THE twelfth annual conference of Educational Associations will be held on January 1-11, at University College, Gower Street, London, W.C.1, under the presidency of Sir Henry Hadow. The presidential address on "The Claims of Scholarship" will be delivered on the first day of the meeting by Sir Henry Hadow. In all, some forty associations concerned directly or indirectly with education will be holding meetings and conferences. Among the papers and lectures to be given are the following, the body responsible and the date being given after the author's name in each case : "The Value of Psycho-Analysis to the Educator," by Miss Barbara Low (Montessori Society, January 1) ; "The Sun and Stars," by Sir Richard Gregory (School Nature Study Union, January 2) ; "Modern Developments in Education and the Outlook for the Future," by Mr. J. Howard Whitehouse and others (Society for Experiment and Research in Education, January 3) ; "School Reform," by Prof. J. J. Findlay (King Alfred School Society, January 4) ; "The Teaching of Hygiene and Racial Progress," by Mrs. Hodson (Eugenics Education Society and Ling Association, January 4) ; "Handwork and Life," by Mr. E. Young (Educational Handwork Association, January 5) ; "Recent Advances in the Relations of Psycho-Analysis to Education," by Dr. J. Glover (British Psychological Society, January 7) ; "Light and Life," by Sir Henry Gauvain (Association of Teachers of Domestic Subjects, January 8) ; "The Question of an International Language," by Prof. F. G. Donnan (International Language (Ido) Society, January 9). An exhibition by publishers of books, maps, etc., has been arranged as in former years, but the exhibits will be placed in the College Memorial Hall where there is more room for an adequate display. Scientific and kindergarten apparatus, etc., will form a separate exhibition.

Societies and Academies.

LONDON.

Royal Society, December 6.—E. G. T. **Liddell** and Sir Charles **Sherrington**: Recruitment type of reflexes. Isometric myograms of the crossed knee-extensor reflex examined in the purely "spinal" preparation present the features interpretable as "recruitment" very much as in the decerebrate preparation. The reflex process answerable for "recruitment" is therefore obtainable in purely spinal centres without the adjuvance of prespinal. An attempt to classify various reflexes on the criterion of presence or absence of "recruitment" is briefly entered on.—G. S. **Carter**: The structure and movements of the latero-frontal cilia of the gills of Mytilus. The structure of these cilia has been investigated by means of the micro-dissection needle. They are complex, and are composed of 10-15 simpler structures which have the form of triangular plates. In the living cilium they are placed in contact one behind the other in the plane of the beat, and together form the blade of the cilium. Their external edges are formed by fibres, which are each attached to a basal granule lying within the cell. These plates will beat independently, and it is concluded that they rather than the compound cilia form the units of ciliary action in these cells. The difference in rigidity shown by the cilium during the two phases of the beat is also shown when a motionless cilium is pushed by the needle in the two directions.—V. B. **Wigglesworth** and C. E. **Woodrow**: The relation between the phosphate in blood and urine. Ingestion by man of doses of the acid and alkaline sodium phosphates containing 1·5-2 gm. of phosphorus causes a rapid 50-60 per cent. increase in the blood phosphate, which then returns very gradually to the normal level. In the dog, phosphate is excreted rapidly by the kidneys instead. The curve of urinary excretion of phosphate runs roughly parallel to that of the blood concentration, but the former varies more widely, and is roughly proportional to the excess above a certain value in the blood. Under conditions in which the blood phosphate is subnormal, normal, or slightly above normal in amount, the concentrations in plasma and corpuscles are identical. When the concentration in the plasma rises far above normal the value for the corpuscles is always lower, whether the plasma value is rising or falling. This unequal partition cannot be explained by the formation of an organic "acid-soluble" phosphorus compound in the corpuscles, for the organic fraction of the acid-soluble phosphorus is not increased by the ingestion of phosphate.—J. B. S. **Haldane**, V. B. **Wigglesworth**, and C. E. **Woodrow**: (1) The effect of reaction changes on human inorganic metabolism. Overbreathing diminishes the phosphates in blood and urine, while carbon dioxide inhalation and sleep increase them. In acidosis caused by ammonium-chloride ingestion the urinary phosphate is increased; while the phosphate of the blood, and also its organic acid-soluble phosphorus, is diminished. Ammonium-chloride acidosis leads to an increased excretion of water, sodium, and potassium, probably owing to a partial loss of electric charge by the body colloids. This is followed by a retention. (2) The effect of reaction changes on human carbohydrate and oxygen metabolism. The alkalosis of over-breathing or bicarbonate ingestion converts the blood sugar into a highly dextrorotatory, unoxidisable form, and also prevents glucose storage; thus causing acetonuria and lowered respiratory quotients and glucose tolerance. Ammonium-chloride acidosis interferes with the storage of glucose, but not with its oxidation. Bicarbonate ingestion raises the resting oxygen consumption; ammonium-chloride ingestion usually lowers it.—J. A. **Campbell**: Concerning the influence of atmospheric conditions upon the pulse-rate and "oxygen-debt" after running. The "oxygen-debt" for 25 minutes after ceasing to run showed, under fixed conditions of experiment, a range of variation of 38 per cent. from day to day; 7-minute debts showed a range of 33 per cent., so should do as well for comparative purposes as 25-minute debts. Atmospheric cooling power had no effect on the "oxygen-debt"; the blood sent in greater volume through the skin in warm conditions is not then taken from the muscles. "Stitch" was the commonest cause of cessation of running in the subjects under observation. Pulse-rate is markedly increased under warm conditions. The oxygen tension surrounding the muscles was increased after exercise.—J. **Gray**: The mechanism of ciliary movement. IV. The relation of ciliary activity to oxygen consumption. In the absence of atmospheric oxygen, ciliary activity continues for about one hour. The whole ciliary mechanism is divisible into three distinct parts: (i.) a reaction which is sensitive to cations (particularly the hydrogen-ion), any interference with which involves a change in the rate of the ciliary beat, but only ultimately leads to a change in the amount of oxygen consumed; (ii.) a mechanism, brought into operation by the presence of an activating acid substance, which is inoperative in the absence of calcium, and in the absence of a certain critical amount of water in the cell. The events associated with this mechanism are independent of the amount of oxygen absorbed; (iii.) a reaction of an oxidative nature which is necessary for prolonged activity. The properties of the ciliary mechanism seem to form a very close parallel to those of cardiac muscle.

Association of Economic Biologists, November 16.—Mr. J. C. F. **Fryer** and J. **Davidson**: The Colorado-beetle problem. Colorado beetle was discovered in the United States in 1829; in Europe, outbreaks occurred in 1877, 1887, and 1914 in Germany, and in 1901 at Tilbury. About a hundred square miles in France, extending into the provinces of Gironde, Landes, Dordogne, and Charente Inférieure, are now infected. The beetle would probably find Britain sufficiently congenial, and would do damage at least equal to the cost of controlling its ravages by artificial means (by spraying potato crops twice yearly). It would arrive in the adult stage, and casual individuals might be expected hidden in merchandise or on board ship, particularly in potatoes from the infested area, or in agricultural produce packed in the area.—J. W. **Munro** and W. E. **Hiley**: The spruce budworm problem in Canada. The term "spruce" budworm is a misnomer for the balsam (*Abies balsamea*), the favourite host plant of the budworm, which is the larva of *Tortrix fumiferana* Clem. A brief description of the forest condition under which the budworm outbreaks occur was given, and emphasis was laid on the system of management of exploiting the eastern Canadian forests in favour of the less valuable balsam. This has caused an unduly high proportion of balsam regeneration in the cut over stands which favours the budworm. An important parasite (*Phytodietus* sp.) of the budworm was absent from these woods. Outbreaks of secondary insects and fungi follow budworm outbreaks. Of the insects, a bark-beetle (*Pityokteines sparsus*), a weevil (*Pissodes dubius*), and a longicorn beetle (*Monochamus scutellator*) are the most important. Fungi, among which the honey-fungus (*Armillaria mellea*) is the most important, spread rapidly during and after budworm outbreaks. After a budworm epidemic the balsam trees that have been

partially defoliated but not killed gradually recover, but a fresh lot of casualties occurs about four or five years after the disappearance of the budworm. These trees, which appeared to have recovered their normal amount of foliage, generally died suddenly during hot weather, and the whole of the crown died at about the same time. Examination of a large number of dead and dying trees failed to disclose any sufficient parasitic cause for the casualties. During and immediately after a budworm attack the breadth of the annual rings is very greatly reduced, and a few years after the epidemic the total thickness of the last five years' rings might be reduced to a quarter of the normal for the pre-budworm period. At the same time the leaf area of the trees has been increasing very rapidly. Thus a time is reached when, during hot, dry weather in July, the water-conducting tissue is insufficient to meet the needs of the transpiring leaves and the crown dies from lack of water. Thus death may be due to a lack of co-ordination between shoot growth and cambial activity.

Zoological Society, November 20.—Dr. A. Smith Woodward, vice-president, in the chair.—W. E. **Le Gros Clark**: Notes on the living tarsier (*Tarsius spectrum*).—Sir Sidney F. **Harmer**: Cervical vertebræ of a gigantic blue whale from Panama.—J. R. **Garrood**: Two skeletons of the cetacean *Pseudorca crassidens* from Thorney Fen, Cambridge.—Dr. Francis, Baron **Nopsca**: Reversible and irreversible evolution; a study based on reptiles.—C. **Crossland**: Polychæta of tropical East Africa, the Red Sea, and Cape Verde Islands; and of the Maldive Archipelago.—Miss Joan B. **Procter**: (1) On new and rare reptiles from South America, (2) On new and rare reptiles and batrachians from the Australian region.

Geological Society, November 21.—Prof. A. C. Seward, president, in the chair.—L. J. **Wills**: The development of the Severn Valley in the neighbourhood of Iron-Bridge and Bridgnorth; with a section on the Upper Worfe Valley, in collaboration with E. E. L. **Dixon**. The area investigated is roughly delimited by the following localities: Much Wenlock, Buildwas, Oakengates, Shifnal, Worfield, Hampton Loade, Morville. Detailed mapping of the drifts has shown, first, that the Buildwas area was as deeply eroded as now in pre-Glacial times; and, secondly, that a belief in the existence of the Iron-Bridge Gorge at that time is incompatible with the distribution of the drifts on the plateau above Iron-Bridge, and with the features of the gorge. The gorge is of late-Glacial origin, and the Worfe Vale was formerly the main drainage-line on the south-east side of the plateau. Practically the whole district was under ice at the maximum of the north-western or Irish-Sea glaciation. When retreat began, the ice-sheet separated into two lobes that remained confluent in the north. The waters of the Glacial lakes formed west and north of the watershed escaped at different times over different cols. One of these overflows is of especial importance in connexion with the origin of the Iron-Bridge Gorge: namely, the Lightmoor overflow, about a mile north of Iron-Bridge. Up to about this stage, the Worfe and its tributaries (one of which now became the Iron-Bridge Gorge) had been engaged in clearing the drift out of their valleys, and in reducing the thalweg of the trunk river to a base-level. Hereafter deposition of the "Main" Terrace of the Severn and of the terrace-like gravels of the Worfe commenced. Long after the initiation of the Iron-Bridge Gorge, ice still covered the upper Worfe Valley. When the ice retired to the north of the watershed hereabouts, Glacial Lake Newport came into being, and subsequently united with the Buildwas Lake on the retreat of the ice-front from the foot of the Wrekin. The outflow at Iron-Bridge thus increased. The subsequent rejuvenation of the Severn below Iron-Bridge was probably brought about chiefly by an elevation of the whole land relative to the sea. Stages in this rejuvenation are marked by terraces.

Royal Microscopical Society, November 21.—Prof. F. J. Cheshire, president, in the chair.—F. I. G. **Rawlins**: The miscroscope in physics. A strong plea is made for the closer union of physics and microscopy, more especially for the undertaking of work in physical optics by the amateur microscopist. Assuming the availability of an instrument fitted with Nicols, a convergent substage system and a Becké lens above the eyepiece, observations can be made of the traces of the family of isochromatic surfaces, each with its characteristic retardation. The work can be made quantitative by employing monochromatic light. If the usual means of obtaining such radiation are not at hand, Wratten filters (especially Naphthol Green) are efficient, though their range of usefulness is limited. The number of fringes observed with objectives of different numerical aperture can be represented by an exponential expression of the form $F = F_0 e^{-AN}$, where F is the equivalent focal length of the objective and N the number of fringes observed (see Rawlins, *Phil. Mag.* xliii. p. 766, and xlvi. p. 992).

EDINBURGH.

Royal Society, November 5.—T. J. **Jehu** and R. M. **Craig**: Geology of the Barra Isles. The rocks are mostly members of the Archæan complex, and these are of igneous origin, the prevalent types being biotite and hornblende gneisses. Muscovite is also present in the more acid types, and locally some of the gneisses are rich in garnets. The foliation planes usually strike N.N.W. and S.S.E., with a dip to the E.N.E. at varying angles. Intrusions into the orthogneisses occur in the form of granulites and pegmatites. The Archæan complex is affected by well-marked zones of shearing, along which mylonisation and the production of flinty crush phenomena can be traced. The macroscopic and microscopic characters and behaviour of the flinty crush material prove that these peculiar rocks are the product of mechanical stresses which at places have raised the temperature to an extent sufficient to bring about partial fusion of the crushed members of the complex, followed in certain cases by incipient crystallisation. The later dykes include olivine dolerites, crinanites, quartz dolerites, and camptonites. Evidences of glaciation are conspicuous, and prove that the ice moved over the islands from S.E. to N.W.—T. H. **Osgood**: Variation in photo-electric activity with wave-length for certain metals in air. As a source of ultra-violet light, a quartz mercury-vapour lamp was used in connexion with a monochromatic illuminator. The metal plates were tested in air at atmospheric pressure, due attention being paid to the "fatigue" which is known to take place under these conditions. The results are of interest and may be of some practical importance in connexion with the physiological effect of ultra-violet light. As the primary cause of the physiological change produced by light is probably photo-electric action, the photo-electric activity of a metal plate may serve as a means of estimating the quality and intensity of the effective radiation.—H. W. **Turnbull**: A geometrical interpretation of the complete system of the double binary (2, 2) form. The double binary form may undergo an algebraic transformation which corresponds to a generalised geometrical inversion. Here the convariants of a (2, 2) form reveal sets of

four or six lines, and special sextic curves with many simple geometrical properties, all connected with a given confocal system of bicircular quartic curves.

MANCHESTER.

Literary and Philosophical Society, November 20.—G. H. **Carpenter**: Warble-flies of cattle. The larvæ of the two common species of Hypoderma (*H. bovis* De Geer and *H. lineatum* Villers) are among the best-known parasites of domestic cattle in the British Isles, in Europe, and in North America; their economic importance is considerable on account of the damage caused to flesh and hides by the large maggots feeding just beneath the skin of the back which they perforate, and also because of the loss of condition suffered by the cattle when they "gad" in summertime to escape from the female fly approaching to lay her eggs. Observations carried on since 1905 by Carpenter and his colleagues in Ireland, by Gläser in Germany, and by Seymour Hadwen in Canada, have shown that the early life history of these insects presents some surprising features. The eggs of both species are generally laid on the legs (from thigh to hoof), rarely on shoulder or flank, never apparently on the back. By examination of the skin after egg-laying and by means of a series of experiments with calves, muzzled so that they could not lick themselves or one another, it has been demonstrated that the mode of entrance into the host's body is not by the mouth. The eggs are hatched on the hairs a few days after laying, and the tiny maggots, less than a millimetre long and provided with strong, sharp mouth-hooks and relatively formidable spiny armature, crawl along the hairs and bore their way directly into the skin. Thence they migrate upwards and forwards to the gullet-wall, the sub-mucous coat of which serves as their resting-place for some weeks or months in the course of their journey through the host's tissues to the final position in the back. The number of larval stages is still to be determined. The gullet-maggot is so much larger (up to half an inch) than the newly-hatched maggot, that it has generally been regarded as representing a second stage, but it possesses mouth-hooks of the same size and form and a spiny armature that is easily overlooked on account of the increase in actual size of the larva, so that the spines are relatively far apart. Hence Gedoelst has recently argued that there is no "moult" between the newly-hatched and the gullet-dwelling larva—only extraordinary growth. On the other hand, Laake concludes not only that the migrating maggot is a second instar succeeding the newly-hatched insect that bores in, but also that there is an antepenultimate instar beneath the skin, differing from the migrating maggot in the total absence of spines on the body-segments.

PARIS.

Academy of Sciences, November 19.—M. Albin Haller in the chair.—G. **Bigourdan**: A project for a French national biography.—M. **Lecornu**: Elastic couplings. A mathematical discussion of the effect of an elastic coupling between a dynamo and its motor on the steadiness of rotation. It is shown to be impossible to decide, in a general manner, whether the elasticity of the coupling is or is not favourable to the regularity of the motion of the dynamo.—Charles **Moureu**, Charles **Dufraisse**, and Philippe **Landrieu**: Remarks on the principle of a general method for determining the heat capacity of solids and liquids and its application to the determination of the water value of calorimetric bombs. The principle of the method suggested by the authors in a previous communication (*Comptes rendus*, 176, 1513) had been anticipated by Pfaundler (1869) and Swietoslawski (1909).—Gabriel **Bertrand**: The transport of copper in the gaseous state and copper-carbonyl. M. Gelinsky has explained a curious example of pseudomorphism by assuming the volatility of copper oxide. This would not appear to be the true explanation of the phenomenon. Copper oxide heated in a stream of either oxygen, hydrogen, or carbon dioxide gives no appreciable transport of the metal even after several hours. But with carbon monoxide there is produced a copper ring, apparently due to the formation of a volatile copper-carbonyl, readily dissociated on heating. The bearing of this observation on the determination of traces of copper in organic substances is indicated: with a brass burner and the material exposed to the gases from the flame, copper may be transferred from the burner to the ash. On the other hand, carbon monoxide formed during the combustion of the organic substance may carry away traces of copper.—Paul **Vuillemin**: New proof of the dystrophic origin of scyphia.—S. **Winogradsky**: The direct method in the microbiological study of the soil. The results of thirty years' work on the microbiology of the soil are, in the author's view, unsatisfactory. The conditions of culture in the bacteriological laboratory are too far removed from the conditions actually existing in the soil, and tend to form new races of organisms distinct from the types in the soil from which they were originally obtained. A scheme of culture is proposed more closely approximating to natural soil conditions.—E. **Baticle**: A mode of compensation for shrinking in concrete arches.—M. **Mesnager**: Remarks on the preceding communication.—E. **Huguenard**, A. **Magnan**, and A. **Planiol**: Research on the surplus of power of birds in flight.—M. **Delanghe**: General method for determining graphically the elements of flight of an aeroplane.—Bernard **Lyot**: Study of the planetary surfaces by polarisation. By the use of a more sensitive polarising apparatus than that hitherto employed, the proportions of polarised light from the planets has been studied. Details of 70 observations on the planet Venus are given.—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the second quarter of 1923. Observations were possible on 86 days during the quarter: the results are summarised in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—J. de **Schokalsky**: The length of the rivers of Asiatic Russia, and on the system of measuring rivers on maps in general.—Maurice **Curie**: Spark spectra in non-metals in the liquid state. Studies of spark spectra between platinum points in bromine, liquid oxygen, fused sulphur, liquid nitrogen, and fused phosphorus. In all cases a continuous spectrum was obtained. The absorption bands of oxygen were clearly shown.—E. **Brylinski**: Michelson's experiment and the contraction of Lorentz.—Léon and Eugène **Bloch**: New extension of the spark spectra of tin and zinc in the Schumann region. Tables of wave-lengths of lines and intensities are given for tin from $\lambda = 1699$ to 1305, for zinc from $\lambda = 1556$ to 1310.—R. de **Mallemann**: The electric double refraction of camphor and carvone.—Edmond **Bauer**: The change of wave-length accompanying the diffusion of X-rays.—Jean **Fallou**: A very simple method permitting the determination experimentally of the dispersion reactance of triphase alternators.—Adrien **Karl** and S. **Lombard**: The estimation of radium in the natural titano-niobates. The method is based on the removal of silica with hydrofluoric acid, fusion with potassium bisulphate, addition of sulphates of sodium and lithium to lower

the melting point, re-fusion and removal of the emanation in a current of air.—Victor **Henri**: The structure of molecules and the absorption spectra of substances in the state of vapour.—M. **Chavastelon**: The diffusion of sulphur vapour in air at the ordinary temperature. Particles of solid sulphur emit vapour at ordinary temperatures, and these diffuse only a short distance from the sulphur particle. The vapour was rendered evident by the stain on silver.—D. **Gelinsky**: The metallisation of organisms. In an attempt to determine the nitrogen in whole insects by the Dumas method, in which the insect was covered with copper oxide, combustion was incomplete. The whole surface was found to be covered with metallic copper, the effect being as though copper had been deposited electrolytically.—J. **Froidevoux**: The estimation of ammoniacal nitrogen in certain nitrogenous materials, and particularly in proteids and their products of hydrolysis.—C. **Gaudefroy**: The dispersion of double refraction in crystals.—M. **Charcot** and Louis **Dangeard**: Researches in submarine geology in the Mediterranean. Cruise of the *Pourquoi-Pas*, 1923.—E. **Rothé**: The principle of a method of exact determination of the propagation of seismic waves.—Marcel **Baudouin**: The markings on the prehistoric clay statues from the cave of Montespan, near Saint-Martory (Haute Garonne), are pittings representing Ursa major.—P. **Nobécourt**: The production of antibodies by the tubercles of Ophrydeæ.—Jean **Charpentier**: Application of the biochemical method of characterisation of galactose to the study of the composition of the pectins. The products of hydrolysis of four pectins from different plants were submitted to the biochemical method described in previous communications: in each case the crystallised β-ethylgalactoside was obtained proving the presence of galactose.—J. **Beauverie**: The circumstances which may modify the effect of the "critical period" on the yield of wheat.—E. and G. **Nicolas**: New observations on the influence of hexamethylenetetramine and of formaldehyde on the bean.—H. **Ricôme**: The intervention of gravity in phototropism.—E. **Roubaud**: The physiological condition of zootropism in mosquitoes. The views of J. Legendre (NATURE, November 17, p. 747) as to certain mosquitoes attacking animals in preference to man require modification: captivity, hunger, or deprivation of water may cause an immediate change in the habits of the insect.—H. **Barthélémy**: Physiological and experimental polysperma in the uterine eggs of *Rana fusca*.—J. **Athanasiu**: The supposed existence of a stimulating wave which is propagated in the myocardium.—M. **Nicati**: Orientation and visual sense of duration.—Jacques **Benoit**: The experimental transformation of sex by early ovariotomy in the domestic fowl.—J. **Chevalier** and E. **Dantony**: The toxic action of the insecticide principle of pyrethrum flowers.

Official Publications Received.

Sixty-first Annual Report of the Government Cinchona Plantations and Factory in Bengal for the Year 1922-23. Pp. 6+xii. (Calcutta: Bengal Secretariat Book Depot.) 8 annas.

University of Illinois: Engineering Experiment Station. Bulletin No. 137: The Strength of Concrete; its Relation to the Cement, Aggregates and Water. By Prof. Arthur N. Talbot and Prof. Frank E. Richart. Pp. 118. (Urbana, Ill.: University of Illinois.) 60 cents.

Federated Malay States. Report of the Secretary for Agriculture, Straits Settlements and Federated Malay States, for the Year 1922. Pp. 16. (Kuala Lumpur.)

Bulletin of the Experiment Station of the Hawaiian Sugar Planters' Association. Agricultural Chemical Series, Bulletin No. 47: A Study of the Phosphates in the Island Sugar Lands. By W. T. McGeorge. Pp. 51. (Honolulu, Hawaii.)

The Transactions of the Leeds Geological Association. Jubilee volume, Part 19, 1920-1, 1921-2, 1922-3. Edited by J. H. Everett. Pp. 59+8 plates. (Leeds.) 5s.

Department of the Interior: The Dominion Astrophysical Observatory, Victoria, B.C. A Sketch of the Development of Astronomy in Canada and of the Founding of this Observatory; a Description of the Building and of the Mechanical and Optical Details of the Telescope; an Account of the principal Work of the Institution. By J. S. Plaskett. Pp. 37. (Ottawa: F. A. Acland.)

Bulletin of the American Museum of Natural History. Vol. 48, Art. 11: Classification of the Lizards. By Charles Lewis Camp. Pp. [illegible]-481. By Charles C. Mook. Pp. 553-562. (New York.)

United States Department of Agriculture. Department Circular [illegible]: The Occurrence of Diseases of Adult Bees, II. By E. F. Phillips. Pp. 34. (Washington: Government Printing Office.) 5 cents.

Diary of Societies.

MONDAY, DECEMBER 17.

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4.30.—W. C. Noxon: Settlement within the Empire.

ROYAL SOCIETY OF MEDICINE (General Meeting), at 5.—Drs. R. Hutchison, Fairbairn, J. Collier, E. I. Spriggs, Crichton Miller, M. Culpin, and J. A. Hadfield: Discussion—Chronic Abdominal Pain in Nervous Women.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—G. R. A. Murray and others: Discussion on Students in Electricity Undertakings.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section), at 7.—F. E. A. Manning: The Management of a Sand and Flint Quarry.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—R. G. Collingwood: Sensation and Thought.

ROYAL INSTITUTE OF BRITISH ARCHITECTS (at 1 Wimpole Street), at 8.—R. Unwin: Higher Building in Relation to Town Planning.

FARADAY SOCIETY (at Chemical Society), at 8.—Discussion on W. H. J. Vernon's Report to the Atmospheric Corrosion Committee of the British Non-Ferrous Metals Research Association.

INSTITUTION OF THE RUBBER INDUSTRY (at Engineers' Club, Coventry Street), at 8.—Col. S. Clarke: The Position of the Rubber Tyre Industry.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Rev. W. Weston: The Influence of Nature on Japanese Character.

TUESDAY, DECEMBER 18.

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting.

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5.15.—H. Faber: Agricultural Production in Denmark, 1909-13 and 1922.

INSTITUTE OF TRANSPORT (at Institution of Electrical Engineers), at 5.30.—H. T. Chapman: Arterial Roads and their Effect upon Transport.

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—W. Sellar: A Basis for the Explanation of Marine Gear Troubles.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—B. C. Wickison: Combination Printing.

WEDNESDAY, DECEMBER 19.

ROYAL METEOROLOGICAL SOCIETY, at 5.—W. H. Pick and S. P. Peters: Note on the Vertical Visibility (estimated looking downwards) at Cranwell, Lincolnshire, during the period February 1922 to June 1923.—Dr. H. Jeffreys: The Cause of Cyclones.—A. W. Lee: The Relation of the Circulation in the Upper Air to a Circumpolar Vortex.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Prof. W. J. Sollas: The Method of Investigating Fossils by means of Serial Sections, and some of the Results obtained.—J. Walton: The Structure and Investigation of Fossil Plants.

ROYAL MICROSCOPICAL SOCIETY, at 7.45.—Dr. R. J. Ludford: Melanin Formation and its Relation to the Nucleolus in a Melanotic Cancer.—Dr. J. A. Murray: Reflecting Analyser for the Polarisation Microscope.

THURSDAY, DECEMBER 20.

INSTITUTION OF MINING AND METALLURGY (at Geological Society) at 5.30.

INSTITUTION OF STRUCTURAL ENGINEERS, at 7.30.—J. B. Clarke: Practical Designing of Structural Steelwork: Beam Connexions and Clarke's Loading.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (at Royal Society of Arts), at 8.—Inaugural Meeting of the Kinematography Group.—W. Day: Kinematography and its Antecedents.

CHEMICAL SOCIETY, at 8.—W. E. Downey: The Relation between the Glow of Phosphorus and the Formation of Ozone.—Prof. T. M. Lowry: The Origin of Mutarotation and the Mechanism of Isomeric Change. A reply to Baker, Ingold, and Thorpe.—F. Challenger and F. Pritchard: The Action of Inorganic Haloids on Organo-Metallic Compounds.—J. F. Wilkinson and F. Challenger: Organo-Derivatives of Bismuth. Part VII. Iodo- and Nitro-Derivatives of Triphenylbismuthine.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, at 8.15.

FRIDAY, DECEMBER 21.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group Meeting), at 7.—A. H. Blake: Pictorial London.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Dr. U. Williams: Fallacy of the Dropped Colon.—Dr. H. A. Harris: Some Problems in Bone Growth.—Dr. R. W. A. Salmond: The Teaching of Normal Radiography and Radioscopy.

PUBLIC LECTURES.

SATURDAY, DECEMBER 15.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: My Excavations in Malta.

THURSDAY, DECEMBER 20.

KING'S COLLEGE, at 5.30.—Prof. C. K. Webster: The League of Nations and Europe (League of Nations Union Lecture).

NATURE

SATURDAY, DECEMBER 22, 1923.

Science in Civilisation.

A STIRRING appeal on behalf of "International Thought" is put forward by Mr. John Galsworthy in a pamphlet just published with that title (Cambridge: W. Heffer and Sons, Ltd. Price 6*d.* net); and in it representatives of science, finance, and the Press are urged to combine to save the civilised world from self-destruction. The most potent director of this triumvirate is held to be science, which has placed in the hands of mankind powers with which it is not fit to be entrusted, as the ethical or moral sense has not kept pace with this development of knowledge. "We have made by our science," says Mr. Galsworthy, "a monster that will devour us yet, unless by exchanging international thought we can create a general opinion against the new powers of destruction so strong and so unanimous that no nation will care to face the force which underlies it."

Mr. Galsworthy is not alone in associating science chiefly with agencies of death and destruction, and in pleading for a curb to be placed upon its powers. It is, indeed, common to regard science as a disturbing influence in human affairs, and to sigh for the simple life away from the restless spirit of inquiry into all things visible and invisible in the universe. It is, however, as futile to rail against the progress of science, or to attempt to prevent it, as to use Mrs. Partington's mop to keep back the rising flood of the Atlantic. Knowledge will grow from more to more whatever the attitude of the public may be towards it. During the last fifty years there have been more scientific discoveries and applications than in the whole previous history of the human race; and we may be on the threshold of developments by which forces will be unloosed, and powers acquired, beyond what have hitherto been known to man. Whether these shall be used to promote social well-being and international amity is not a question for science, but for the public and its leaders. While nations look to war as the ultimate means of deciding disputes, they will seek to possess themselves of the most powerful means of imposing their wills upon others. As Prof. Soddy recently remarked, should it be possible ever to release the great store of energy in the atom, the first use that would be made of it would be to construct a new bomb.

It is only by such an international understanding as is suggested by Mr. Galsworthy that this misuse of scientific discovery can be avoided, yet, in spite of the existence of the League of Nations, the signs of the times are not very favourable towards the unity of mankind. Science itself is international, and the results of research are free to all for any purpose. In the hundreds of scientific papers published weekly in the

world, there is scarcely one deliberately concerned with providing any fighting service with more effective means of destruction, and not one scientific worker in a hundred sets himself intentionally to make such a discovery or invention. It is just as impracticable, however, to prevent the wrong use of scientific powers by individuals as it is to prevent literary people from the misuse of their genius for purposes of gain. The facts of science are as free as the words of our language, and in both cases they may be used for the uplifting of mankind or for its degradation.

The truth is, as Mr. Baldwin remarked in his speech at the Guildhall on November 10, the present troubles in the world are largely owing to the fact that while men have learned to control forces of Nature they have not learned to acquire control of themselves. He urged that more pains should be taken to apply the methods of science to human problems, and by that he obviously meant not the development of poison gases and high explosives, but the principle of facing facts honestly and fearlessly, and basing just conclusions upon them. The methods of science should be the methods applied to social problems if sound principles of progress are to be determined. The Labour Party's recent manifesto says nothing of what science has done or may do to improve the world in this way, but asks, "Can the method of science be applied to nothing save the organisation of men for war and their equipment with instruments of destruction?" We have here a paraphrase of Ruskin's assertion that "The advance of science cannot be otherwise recorded than by the invention of instruments to kill and put down noble life"—a view in which distorted vision is combined with the sin of ingratitude.

Modern civilisation is built upon science, and almost all industrial developments had their origin in principles or substances discussed in scientific laboratories by investigators working purely for the advancement of natural knowledge. The principle that a moving magnet can create a current of electricity in a coil of wire near it, discovered by Faraday nearly a century ago, led to the construction of the dynamo, and was the seed from which the great industry of electrical engineering has grown. It is estimated that this industry now represents a capital of more than one thousand million pounds, and it could not have existed without the discovery by Faraday of the fundamental principle of all electro-magnetic machinery. All the pure copper required for this machinery and electrical purposes generally is produced by electrolysis, and here again the principles used were discovered during scientific investigations by Davy and Faraday. Aluminium—that most useful metal, which is destined to compete with iron and steel in its importance—is now manufactured exclusively by electrolysis of a fused mineral containing it.

The electric furnace was first used by the French chemist, Moissan, in scientific research; and now it is employed for the production of hundreds of thousands of tons of steel annually. Calcium carbide, used so extensively in the production of acetylene gas for house lighting and motor lamps, and for oxy-acetylene welding, is entirely manufactured by heating lime and coke together in an electric furnace. The discovery of X-rays was an incidental result of researches into the nature of electricity, and the existence of electric waves, which led to wireless telegraphy and telephony, was first proved in a laboratory. Long before the thermionic valve had made the wonderful achievement of broadcasting possible, the effect upon which it is based was the subject of scientific investigation, and studies of the emission of electrons disclosed the principle upon which it depends.

Nearly a century and a half ago it was shown by Priestley and Cavendish that, when electric sparks are passed through air, some of the nitrogen and oxygen combine to form oxides from which nitric acid or nitrates may be afterwards obtained. This is the principle of the process by which hundreds of thousands of tons of nitrates are now produced annually in Norway for use as agricultural fertilisers in the place of saltpetre from Chile. The process needs, however, a supply of cheap electric power to make it commercially profitable.

When Germany was cut off from natural supplies of nitrates during the War, she had to obtain what she wanted from the nitrogen in the air, and was so successful that more than a million tons were produced in 1918. The method used was based upon the principle of catalysis, whereby chemical combination is promoted by the presence of small quantities of particular elements, which thus act as matrimonial agents. Nitrogen and hydrogen were passed under pressure over finely divided iron, and a certain amount of the two gases combines under these conditions to form ammonia, which, by being passed with oxygen through tubes containing another catalytic agent, may be converted into nitric acid. The hydrogen required for combination with atmospheric nitrogen is obtained by electrolysis of water, or from water-gas and steam by a process depending upon catalysis. The nitrogen is obtained by distilling liquid air. Nitrogen is more volatile than oxygen, so it distils off first and the two gases may thus be separated.

The methods used in the manufacture of liquid air and other gases, and in modern refrigerating machines generally, are based upon scientific experiments by Joule and Kelvin on the phenomena attending the free

expansion of gases. They found that, when air issues from a small orifice, a fall of temperature is experienced amounting to half a degree Fahrenheit for each atmosphere of difference of pressure between the two sides of the orifice. The great refrigerating industry thus had its origin in the discovery of a purely scientific principle.

It is the same with substances as with principles and processes—they are first found as the result of scientific research and are afterwards used, often after a long interval. The metal tungsten used for the filaments of electric bulb lamps and thermionic valves was scarcely known outside scientific laboratories a few years ago. It was discovered about 1785, but its uses were not understood until nearly a century later. It is an essential constituent of high-speed tool-steels, which require to be not only extremely hard but also to maintain their hardness at high temperatures, even at an incipient red-heat. Tungsten steel is also used for the permanent magnets of telephones and the magnetos of every motor car and aeroplane. Manganese was in existence long before it was made an ingredient of the famous Hadfield steels, used for the helmets of British forces during the War, armour-plates, tramway points, and many other purposes. Chromium is used in the making of stainless steel; titanium, molybdenum, nickel, vanadium, and other elements are similarly employed to give special properties to steels, yet all these elements were discovered by scientific investigators without a thought of their practical value. Thorium and cerium, used in the manufacture of incandescent gas mantles, of which about four hundred millions are made annually, were products of the chemical laboratory many years before they gave rise to a large industry; and even the air-burner itself used for such mantles and in all gas fires was first devised and used by Bunsen for laboratory purposes.

Every scientific discovery, however remote it may seem at the moment from the ordinary practical needs of life, may be the seed from which will grow a mighty tree under which man will build his industrial tent. When argon was isolated from the air in 1895, no one regarded the discovery as of any practical importance, yet the gas is now used in half-watt and other gas-filled electric lamps as the most suitable for the purpose. Neon, isolated from the atmosphere a little later, is widely used for the brilliant pink glow lamps of illuminated advertisements, particularly in Paris, where it is a by-product of the manufacture of liquid air. Probably the most remarkable example of this kind is afforded by the gas helium, which was detected in the sun by Lockyer and Janssen in 1868, twenty-six years later was extracted from cleveite by Ramsay, and is now produced to the extent of thousands of cubic feet daily from natural gas wells in the United States for the inflation of dirigibles and other air-ships. As it is non-inflammable and non-explosive, it has decided advantages over hydrogen for this purpose and is only slightly heavier.

Before things can be used in any way they must be discovered, and it is the particular function of science to reveal them. It is the business of the scientific investigator to discover, of the engineer or inventor to recognise and apply the results achieved, of the artisan to employ his skill in making them commercially profitable, and of the community to see that they are used to promote social welfare. If the world has not been made any happier by what science has given to it, the fault is with the human race itself and not with science. Happiness is a relative term, and no two individuals have the same cup with which to measure it. The beast in the field, or the pig in its sty, may be considered by some people as emblems of content, and if these be the standards to use, then modern man may envy the cave-dweller of prehistoric times. We cannot, however, avoid progress, and whether this is accompanied by increased happiness or not depends upon ourselves. We live in a beautiful world, yet how few there are who find delight in it or raise their eyes to the starry heavens above them. The gifts of God are for those to enjoy who will, and the gifts of science may likewise contribute to the uplifting of the human race if they are rightly regarded, or its degradation if they are not. The attitude of civilised man towards new scientific knowledge at this epoch of the world's history is that of a child playing with fire. It is necessary now more than ever to teach him the strength as well as the danger of the element in his hands, and to cultivate the desire to make the noblest use of all things which are granted to him through the achievements of workers for the advancement of natural knowledge. When this spirit prevails, the human race will prove itself worthy of the opportunities which science gives for social and spiritual progress, and man may indeed become but a little lower than the angels.

The Valuation of Mines.

Mineral Valuation. By Prof. Henry Louis. Pp. x+281. (London: C. Griffin and Co., Ltd., 1923.) 15*s*. net.

THE principles underlying the valuation of mines, whether for the purpose of sale or probate, the raising of loans, investment, or taxation, are not so fully comprehended, except by few mining engineers, or so widely known as they should be. Consequently, in the matter of actual valuations, judging from those which have come before us, these principles are

frequently incorrectly applied. In the case of valuations for assessment of Poor Rate the abjuration of principle is, perhaps, most manifest.

Books on the subject of the valuation of mines and minerals are not numerous, and some, like Hoskold's "Engineers' Valuing Assistant," are either out of print or, in some measure, incorrect. We welcome, therefore, the appearance of Prof. Louis's admirable contribution to the subject.

The work covers, in seven chapters, a fairly wide field, treating, as it does, of the principles of valuation, ownership of mineral leases and concessions, sampling, explanation of the formulæ in use, examples in the valuation of coal and metalliferous mines, and valuation for special purposes, *e.g.* rating, etc. Chapter ii., relating to "Mineral Deposits," is perhaps the best in the book, the occurrence of minerals being a subject of which Prof. Louis has had wide experience and on which he has written much. Under this head he describes simply and with lucidity the manner of occurrence of minerals in beds, veins, and masses, indicating the variations in point of value to which they are subject.

His dissertation on the "probability of error" in the determination of the thickness of deposits for computation of the contents (chapter iii.) is of much interest; but the method usually adopted by mining engineers and alluded to by Prof. Louis on p. 50 is, perhaps, as satisfactory as any other method, namely, "after calculating average values as closely as the available data permit . . . to deduct a certain percentage 'for safety.'" The author is insistent, and rightly so, on the impossibility of assigning "to any mineral property an absolutely definite value, but only a most probable value." Whilst this is particularly true of a mineral property, by reason of the variations in regularity of deposits, of selling prices, and the general risks attendant on mining, it is of course true also, to a lesser extent, of other things as well, *e.g.* agricultural land, owing to the risks to crops due to bad seasons, variation in selling prices, etc. To meet the greater uncertainty of mines, valuers allow in the computation of the value of the annuities an unusually high rate of "remunerative" interest.

The debateable subject of subsidence of the surface due to extraction of minerals (as to which a Royal Commission, of which Prof. Louis is a member, is at present inquiring) is touched upon, and the author rightly says (p. 69), "It will be seen that we are still very far from having arrived at anything like an accurate estimate of the requirements in any given case, and it will always be well to be guided by local experience obtainable from previous workings whenever such is available." But the author might, with advantage, have mentioned Fayol's theory of the dome which reconciles so many of the seemingly contradictory results of different observers regarding subsidence, this theory being to the effect that in stratified deposits the zone of subsidence is limited by a sort of dome, which has for its base the area of the excavation; the extent of the movement diminishing the further one goes away from the centre of that area.

The question of depreciation of plant enters into mine valuations; it may, indeed, be an important item: an immense sum is often expended on the plant, for example, of a deep modern colliery. In making the allowance for depreciation, Prof. Louis criticises what he terms the income tax method; "it is charged each year upon the value of the plant less the amount of depreciation written off the previous year." He says, seeing that the plant can never come down to zero, and that, under the method he criticises, the amount written off for depreciation is a maximum when the machinery is new and becomes very small as the machinery gets older, the method is wrong. The value of the plant at the termination of the lease—if the property is leased—of course depends, amongst other things, on whether the minerals in the leasehold are exhausted or not, and on the site of the mine; and, on the second point, at a well-managed mine renewals of machinery and plant are carried out to a considerable extent during a long-termed lease, which to some extent militates against Prof. Louis's criticism, though not entirely.

Chapter v. treats of "Formulas and Calculations." Why, by the way, does Prof. Louis prefer this plural to the one in common use—"formulæ," and, whilst on the subject of grammar, why does he prefer "under these circumstances" to "in these circumstances"? The formulæ are mainly those familiar to students of Hoskold's "Engineers' Valuing Assistant" and King's "Theory of Finance," the latter being the best work, known to the present reviewer, on the doctrine of interest and annuities certain. The exigencies of space forbid a detailed review of this section of the book, but it may be noted that the author directs attention to the necessity of making the proper and necessary deduction for income tax in the calculation for the recovery of capital. Likewise, "if the capital be invested in the purchase of mineral rights . . . it becomes further liable to mineral rights duty in accordance with the Finance (1909–1910) Act," namely, 1*s.* in the pound. It is not generally realised what a difference there is between the gross and net income derivable from the ownership of mineral lands; mineral rights duty being chargeable *after* the deduction of income tax.

On the vexed question of the proper formula to apply for the determination of the present value of a deferred annuity in which two rates of interest are involved, Prof. Louis recommends (p. 101) that which was, we believe, first put forward by Mr. George King, and is accepted by the Inland Revenue in valuations for the purposes of probate. The simplest form in which this can be stated is that given by the reviewer in a work of which he is joint-author, namely, where:

Y.P. = years' purchase.

a = the amount to which 1*l.* per annum accumulates in e years at r per cent.

A = the amount to which 1*l.* per annum accumulates in t years at r per cent.

r = the accumulative low rate of interest.

R = the remunerative high rate of interest.

d = the period of deference.

e = the period of enjoyment.

t = the total period $= d + e$.

Then
$$\text{Y.P.} = \frac{a}{1 + \frac{\text{AR}}{100}}.$$

Allusion has been made at the commencement of this review to want of adherence to fundamental principles in valuation of mines for purpose of assessment of rates, the basis of which is, by law, the annual value. There are no less than sixteen different methods of assessment in use in England and Wales, but there can be no doubt that the fairest is that advocated by Sir E. Boyle, namely, to value the surface works and plant as the non-directly productive works of a railway are valued, and the mine on the gross receipts upon coal raised, excluding colliery consumption, and deducting therefrom the expenses incurred in getting and raising the coal, *i.e.* to take as the value the net income derivable from the coal.

All who seek enlightenment on this and other branches of the subject of valuation of minerals cannot do better than study Prof. Louis's admirable and comprehensive work. Richard Redmayne.

Dutch Potters and their Work.

Old Dutch Pottery and Tiles. By Elisabeth Neurdenburg. Translated with Annotations by Bernard Rackham. Pp. xv+155+59 plates. (London: Benn Bros. Ltd., 1923.) 84*s.* net.

It is a pleasure to welcome this competent, scholarly, and interesting account of that renowned pottery-work of the Dutch craftsmen and artists which exercised such a profound and quickening influence on the potter's art as it was practised in all the countries of northern and central Europe, especially during the course of the eighteenth century. We already possess, in English, quite a number of small handbooks which treat of this important subject; but here, at last, a volume is presented which may be acclaimed as worthy and complete in its text, and is also so handsomely illustrated as to satisfy every requirement of the collector.

One praiseworthy feature, which immediately arrests attention, is the frank simplicity with which the many troublesome questions concerning the date or even the period of the various types of pottery and tile-work manufactured in the different towns and provinces of Holland are discussed and their origins elucidated. The factories at Delft, most famous of Dutch pottery-towns, are described at length, and we have interesting personal accounts of their proprietors and the principal painters in their employ; though we are still, fortunately, in the time when the proprietor of a pottery was his own principal artist or master-craftsman. The factories at Rotterdam, Haarlem, The Hague, and those in the province of Friesland are not overlooked, though, as is only to be expected, they do not receive the same detailed notice, for their pottery was not of the same importance either in quantity or in technical excellence.

The descriptive account of the native peasant-pottery and tiles, enriched with decorations in "slip" or with more ambitious designs in "sgraffiato," strikes one as somewhat meagre and unilluminating. This is a matter for regret, when we remember the extensive and splendidly decorative use which was made of these simple methods by our English potters of the seventeenth and eighteenth centuries.

Of the famous tin-enamelled wares, with their brilliant and effective painted decoration in blue or in polychrome, the book gives an excellent and convincing account. We are shown, by a documented narrative, how the processes were first introduced into Holland and how the mingled stream of Italian and Spanish influence fertilised the native art of the Dutch potters; either as a result of the incursions of Italian and Spanish pot-painters or from the return of Dutch potters who had travelled abroad for the increase of knowledge. Thus, an account is given of one, Hendrik Vroom, who travelled to the south of Europe to become qualified as a painter in oils but repeatedly earned his living while pursuing his studies by serving as a painter of pottery; working in Seville for an Italian potter and, later on, at a majolica factory in Venice. By such interchanges the art and craftsmanship were both improved, for the Dutchman sharpened himself on the more fiery metal of the South; so that, when he turned in earnest to the reproduction of Oriental designs, borrowed from the fashionable porcelain of the Far East, he was so well equipped that he was able to take full advantage of the lessons taught by the greatest of

all decorative artists. How fully the lesson was learnt has been demonstrated again and again, as when, on close examination, among a set of Chinese vases used for the adornment of a mantel-shelf one will be found to be a Delft-ware copy of a broken original.

The most famous of the Dutch potters and pottery-painters, such as De Keizer, Pijnacker and Frijtom of the seventeenth century and Van Eenhoorn and Fictoor, who were at work early in the eighteenth century, as well as the later painters like Hoppesteyn and Adrien Pijnacker, are fully dealt with and the characteristic details of handling or treatment by which their work may be distinguished are clearly explained. Valuable and interesting as the work is, it is more than a little disconcerting to find the author indulging in such an unwarrantable statement as is contained in the last paragraph, where she states that when the Staffordshire earthenware of Wedgwood and his compeers displaced the tin-enamelled wares by their fine and eminently serviceable qualities, "The wares which had been the pride of Holland, possessing in their soft, pleasant enamel and cheerful, harmonious colouring a charm unequalled even by Chinese porcelain, went under before the output of an industry to which Dutch craftsmen had given its start." One is inclined to rub one's eyes and wonder if the words flow from some ultra-patriotic writer who, not content with the assured position always accorded to the wares of her native country, must needs exalt them above their proper place by challenging the finest pottery known among men. William Burton.

A Lover of Mountains.

Below the Snow Line. By Douglas W. Freshfield. Pp. viii + 270. (London: Constable and Co., Ltd., 1923.) 18*s.* net

Mr. Freshfield has been, as he tells us, "as much a traveller as a climber," and he offers these "selections from old records of travel" in the hope that they may "convey to a few kindred spirits suggestions of alternative playgrounds near and far off, accessible at times when the High Alps are practically closed." But neither the title of the book nor the innuendo of these sentences must be taken literally. They do no justice to the scope of Mr. Freshfield's journeys, to the amount of true exploration involved, or the depth of the author's knowledge of mountains and mountain ranges, or his great love for mountain travel. After all, they "half reveal and half conceal the soul within." Perhaps the title was a mere chance repercussion from that of Mr. Clinton Dent's "Above the Snow Line." It serves at least to prove that to the true mountaineer all things fall to be considered in relation to the snow line. The lower slopes have no absolute value, save as they lead to the higher, or, if they have the misfortune to be so situated geographically as to have no higher slopes, they are to be considered as opening a prospect of the great hills, or, if even this be denied, as illustrating them in reminiscence.

There is indeed more in it than that. Mr. Freshfield is in grain a traveller; and, though we can scarcely conceive of him as travelling without a mountain as a goal or as a background, his interest in mountains does not consist solely in getting up and down them. He has, it is true, been engaged in doing so for a period that includes almost the whole of the history of modern mountaineering. Mr. Alfred Wills ascended the Wetterhorn in 1854. Mr. Freshfield published "Thonon to Trent" in 1865. A great many things have happened since then. Trent has changed both its nationality and its name, and a whole system of Alpine theory and technique has been evolved. But during all that time Mr. Freshfield has continued to find pleasure on one side of the snow line or another, and to delight those who take the same pleasure by telling them, on occasions all too rare, what he found there and why he liked it. How many summits must his foot have trodden? How many mountain valleys must he have known?

> "Conturbabimus illa, ne sciamus,
> Aut ne quis malus invidere possit,
> Cum tantum sciat esse. . . ."

Mr. Freshfield brings to his task of communicating his pleasure to others qualities more valuable than mere experience. He has an ironic wit, wide reading, and a retentive memory, and he has always written as a scholar and a man of taste. The hardships and discomforts of mountaineering are easier to bear when encountered with a certain rough jocularity. But that which cheers on the hillside is often intensely depressing in the study, and the stock Alpine joke, preserved like a fly in amber in the pages of the Alpine periodicals, has a shrunken and almost repulsive appearance. Mr. Freshfield does not disdain to jest. But he is too witty to be facetious.

Mr. Freshfield will always be associated, in particular, with those Italian Alps which he made his own in the years before 1875 and to which he allured his countrymen by the volume published in that year. That charming book must have sent so many people to the district of which it treats that it is difficult to think of Mr. Freshfield without Val Maggia, or of Val Maggia without Mr. Freshfield. This book cannot hope to make so wide an appeal. It does not happen to every lover of the mountains to have the time to visit Japan or the Mountains of the Moon or the Kabyle Highlands. Not all of us, even if we had time, have the capacity for enduring heat which enables

Mr. Freshfield to take a midsummer holiday in Corsica. Still, here is a fine feast for all who like to commune in spirit with a fellow-lover of the hills. The papers entitled "Behind the Bernina" (Val Malinco, Val Masino, and Val Codera) and "The Bergamasque Alps" are a sequel to "The Italian Alps," and in revisiting these enchanted glens the author recaptures and reproduces the charm of "that large utterance of the earlier gods." The Maritimes and the Gran Sasso are exactly the setting for him, and wherever Mr. Freshfield goes he takes with him the classic writers who have fed his imagination and formed his style. It gives a certain pleasure to catch him out in a misquotation, and that from Milton, a common misquotation from whom dogs Mr. Freshfield's name. It will be found on page 46.

Expositions of Atomic Physics.

(4) *Modern Electrical Theory.* By Dr. Norman Robert Campbell. Supplementary Chapters. Chapter 17: The Structure of the Atom. (Cambridge Physical Series.) Pp. x+161. (Cambridge: At the University Press, 1923.) 10*s.* net.

THE theory of atomic structure has, during the past few years, reached a stage of sufficient success and stability for it to be possible to describe many of its features in a simple manner. There is a general agreement as to the validity of certain fundamental conceptions, such as the nuclear structure, the interpretation of isotopes, and the general functions of the outer electrons, while, to turn to more delicate points, the quantum theory and the wave theory of radiation, like an ill-assorted couple of individually worthy people, have learnt to live together in peace by a tacit agreement not to insist too much on each other's faults, so that it is possible for their friends to ignore their essential incompatibility. In short, the times seem propitious for popular summaries of recent advances in molecular physics, and a large number of such books, appealing to various circles of readers, have recently appeared, some of which are now before us.

(1) England is traditionally successful in the writing of simple scientific expositions for general reading, so that it is the more astonishing that two of these books should be translations from the German, and that these two should be but representatives of a large number of such translations not of works, like Sommerfeld's celebrated treatise, distinguished by great learning and great industry, but of ordinary lectures and essays peculiar for neither novelty of matter nor elegance of exposition. It is difficult, for example, to find any compelling reason for the appearance of Prof. Graetz's book in English dress. This summary of recent atomic theory was written while the War was still in progress (in fact, part of it is based on lectures delivered in territory occupied by the Germans), and, while it has been revised by the insertion of new matter, imperfectly incorporated with the old, the last revision was nearly two years ago. In consequence, the book is seriously behind the times. To take one example only: it is stated, in what purports to be an exposition of Bohr's views, that the electrons are arranged in concentric rings, each ring containing a number of electrons, the model for neutral helium, in particular, being figured with two electrons at opposite ends of the diameter.

Apart from being out-of-date, the book is vitiated by a deplorable looseness of expression which is very liable to mislead the general reader for whom it is intended. We are told that radium emanation loses its activity, "unlike radium, thorium, etc., which keep their activity for ever"; that for reflection to take place, X-rays must fall on the crystal at practically grazing incidence; that the nuclear charge determines the ordinal number in the periodic system, "and therefore determines also its atomic weight." The account of positive rays is bad. In short, the author does not seem to be sufficiently familiar with his material. Altogether, the book is superfluous, and it is a pity that such praiseworthy production in the matter of paper and print as it enjoys should not be devoted to a better object.

(2) The book of Prof. Haas's is a better performance, but is scarcely what it is implied to be, a book for laymen. In a hundred and fifty small pages, the author runs quickly through the electromagnetic theory, the kinetic theory of gases, the electron theory, the quantum theory, recent work on the structure of the atom, and the theory of relativity. It is scarcely necessary, in the face of this programme, to labour the fact that the treatment is far too laconic to be of use to any one with but little foreknowledge of the subjects handled. The language is simple enough, but such features of modern physics as the conception of a black body, the gyromagnetic effect, the quantum of action, and so on, cannot be clearly explained in single paragraphs by the mere device of omitting mathematical symbols.

The book gives a good summary of those branches of knowledge which it handles, a summary which can be read with profit by young students who want to get a general view of what they are learning: it is more like an index than an exposition. Many will differ from the translator, who has otherwise performed his task well, over his decision to express the extreme numbers, usually written in index notation, in words, such as a "quadrillionth part of 1½ grams," or "800 billion per second." It is true that he gives a table of this notation in his introduction, but the scheme is of doubtful advantage.

(3) Now Mr. Bertrand Russell has succeeded in writing a book on the atom which is really accessible to the general reader. He uses a simple and lively style, which does not disdain to find in the flea "which crawls for a while and then hops" an image of the motion of the electron in the Bohr atom. His book is very readable, and gives what is in the main a very good account of the fundamental features of modern atomic theory. Unfortunately, Mr. Russell's unfamiliarity with the practical side of physics has led him into some extraordinary statements, such as that a spectrum which is "a continuous band of colours, like a rainbow," is called a band spectrum, or that fluorescence is "the subsequent emission of light of exactly the same frequency as that which has been absorbed," or that, "broadly speaking, there are three lines, the K, L, and M lines, which make up the X-ray spectra." The author makes an attempt, which seems a little too ambitious, to expound Hamiltonian mechanics without symbols. He has, obviously, written mainly under the influence of Sommerfeld's book: to have rendered some of the main lines of thought in that book comprehensible to a wide circle of readers is no mean feat.

(4) Dr. Norman Campbell appeals to a different circle, that of students who are specialists in physics. He continues the task of bringing parts of his "Modern Electrical Theory" up-to-date by means of monographs which he calls chapters. The book before us shows some of the valuable qualities which physicists have learnt to associate with its prolific author, whose impulsive claim and vivacious enthusiasm in the cause of progress find frequent expression in such a passage as:

"If we are hidebound by tradition, let us by all means stick to Amperean and Maxwellian theory, reject as a pernicious heresy, unsanctioned by the Fathers of the Church, all modern theory of spectra; let us retire as hermits to the desert of ignorance and refuse to have any dealings with the wicked, bustling world of modern science. If, on the other hand, we believe that progress in science is not impossible, and that the age of discovery did not end abruptly in 1870, let us be confident in our beliefs, and attribute to genius in our own time an authority no less and no greater than that of our intellectual forbears."

It is regrettable that this spontaneity of utterance seems to be allied to a breathless haste which has led to the omission of all mention of important pieces of work, and a certain carelessness which impairs much that has been written. It is, no doubt, outside the design of the book to devote attention to the methods of experiment by which the knowledge has been won, but, even so, it seems questionable to say of the positive rays that they "are never homogeneous in velocity," and so to ignore all Dempster's work. It is scarcely fair to Aston to say that he merely "re-designed Thomson's apparatus." It is strange to refer in detail to the discrepancy between the Bohr and the Weiss magneton, and to say nothing of Pauli's theory or of the work of Gerlach and Stern. Nobody is more impressed with the advisability of correctness in dimensions than Dr. Campbell, and yet he gives h, a unit of action, in ergs on page ix, while according to his equations on page 82 and elsewhere it is erg cm.! The notation is at variance with that of chapter xv., and is not consistent in the book itself. The index is futile.

Unfortunately these faults are but typical: it would be a distasteful task, but an easy one, to extend the list. Maturer reflection would, it seems certain, have led Dr. Campbell not only to introduce certain modifications in his exposition, but also to cancel his abuse of Sir William Ramsay, which serves no good purpose. The conclusion is irresistible that the author could have written a very much better book if he had only been willing to take more trouble and more time over it.

Our Bookshelf.

Electrical Engineering Practice: a Practical Treatise for Electrical, Civil, and Mechanical Engineers, with many Tables and Illustrations. By J. W. Meares and R. E. Neale. Fourth edition, rewritten and enlarged. In 2 vols. Vol. 1. Pp. x + 584. (London: Chapman and Hall, Ltd., 1923.) 25s. net.

In the new edition of Meare's and Neale's "Electrical Engineering Practice," the scope of the work has been widened and the matter has been suitably rearranged. The book is thoroughly up-to-date and reflects clearly the present state of the industrial knowledge of electrical engineering in Great Britain. The authors are a little hampered at times by having to keep closely to the specifications and nomenclature definitions of the British Engineering Standards Association (the B.E.S.A.), the Wiring Rules of the Institution of Electrical Engineers, and the recommendations of the International Electrical Commission. The B.E.S.A. has always many committees sitting revising specifications for materials, machines and apparatus and dealing also with nomenclature and symbols. As these specifications are issued periodically it is not easy for authors to keep pace with them. The committees are not necessarily bound by their previous decisions. For example, the older generation of electricians recom-

mended that "continuous current" and "virtual value" should be used instead of "direct current" and "effective value." The younger generation has simply reversed these decisions. Our sympathies are with the authors who strive to model their nomenclature on the very latest recommendations, and find later that changes have been made. The constant strivings of electrical engineers after standardisation in specifications have done much to stabilise the industry.

The authors in many places where there is doubt give the variants, as, for example, effective virtual and root mean square (R.M.S.), ground and earth, and several other synonyms. They measure both magnetic induction B and magnetic force H in the same unit, namely, the gauss, which is defined to be one line of magnetic flux per square centimetre.

From the teacher's point of view, however, this leads to hopeless difficulties. We can recommend this book to those engineers who have a sound knowledge of theory and want to know the latest practical problems which the engineer has to solve.

Geologic Structures. By Bailey Willis. Pp. xi+295. (New York and London: McGraw-Hill Book Co. Inc., 1923.) 17*s.* 6*d.*

THIS book is essentially different from James Geikie's "Structural and Field Geology," which makes its appeal through its fine presentation of rocks as they actually appear on bare surfaces of the crust. The two works may well stand side by side. Prof. Bailey Willis concerns himself here with the mechanics of rock-displacement and rock-folding, and illustrates these by photographs of his series of models made to illustrate the structure of the Appalachians. He uses mixtures of wax, plaster, and turpentine, producing strata that yield very variously to mechanical stress. The deformation of an incompetent series under load provides material that returns, as it were, into the core of a rising arch formed by competent strata that can lift a load when laterally compressed, or into the core of a syncline when the competent series lies below them and is bent downwards, displacing matter in the depths (p. 148). Hence we have highly crumpled series between strata of more simple curvature. The shearing of materials in sediments as well as in schists, so that new parting-planes are set up, accompanied by thinning and elongation of the mass, is frequently brought before us in this stimulating volume. Moreover, we never lose sight of the tridimensional character of the structures described. There is a valuable chapter on field-methods, in which the author remarks (p. 28) that "the explorer should have the pluck of an American and the self-respect of a Chinese." The book provides geologists with very pleasant reading.

G. A. J. C.

Differential Equations. By Prof. H. B. Phillips. Pp. vi+78. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 6*s.* 6*d.* net.

DR. PHILLIPS's little book is not a treatise on differential equations in the ordinary sense. He does not deal with any but the most elementary equations, and his aim is purely utilitarian, namely, to provide "thorough drill in the solution of problems in which the student sets up and integrates his own differential equation." There are a very large number of problems, with some worked out in the text. The problems are from all branches of applied mathematics, physics, physical chemistry, etc. We can certainly advise students of these subjects to become acquainted with the easier types of differential equations through the agency of Dr. Phillips's attractive and readable book.

A few criticisms of detail may perhaps be allowed. In the example on p. 6 the minus sign should be used *at once* in the form $dR/dt=-kR$, instead of leaving the negative in the form of an incidental result of the calculation. On p. 25 something should be said about the geometrical properties of homogeneous equations of the first order. The definition of phase angle on p. 66 is incorrect. There are also a number of mistakes and misprints.

S. B.

An Introduction to the Study of the Compounds of Carbon, or Organic Chemistry. By Ira Remsen. Revised and enlarged with the collaboration of the author by Prof. W. R. Orndorff. (Macmillan's Manuals for Students.) Pp. xii+567. (London: Macmillan and Co., Ltd., 1923.) 10*s.* net.

REMSEN's text-book has for many years been regarded as perhaps the best introduction to organic chemistry. It is extremely well written and not obscured by tedious details, and is well within the student's capacity. Theory is kept within bounds, and one feels that to the author, at any rate, organic substances are not chalk marks on blackboards. In the new edition the essential character of the book is preserved, but by omitting illustrations and directions for experiments, it has been found possible to bring the text thoroughly up-to-date and to include some rather more advanced material. Very little calling for criticism can be found, but it is suggested that the theory of esterification on p. 67 is unsound, and that ethylene is not most conveniently prepared from the dibromide (p. 276): Newth's method is not even mentioned. Again, on p. 282, some account should have been taken of Chattaway's work. Apart from such trifles, the book is clear, up-to-date, and accurate, as well as readable.

Tracks of British Birds. Edited by H. Mortimer Batten. Life size. Printed on cloth chart, 20 in. by 30 in. (Edinburgh and London: W. and A. K. Johnston, Ltd., 1923.) 4*s.* net.

THIS forms a companion chart to "Tracks of British Animals," already noticed in these columns, and follows the same general lines. Four categories of birds are represented, namely, swamp birds, ground birds, perching birds, and birds of the seashore, each with about ten examples. The tracks are reproduced life-size, and a few brief explanatory notes on the general subject are given at the foot of the chart. Organisations such as Boy Scouts and Girl Guides, in which instruction in the craft of the country side occupies a good deal of attention, will find this chart invaluable, and it will be welcomed by teachers of Nature Study in schools as a most useful aid to the teaching and cultivation of powers of observation. The use of the word mavis as the common name of the song-thrush is, we believe, only general north of the Tweed, and we suggest the addition of the latter name for the benefit of those who are not familiar with the Scotch term.

Letters to the Editor.

Hydrone and Water: Thunderstorms and Globe Lightning.

PROF. ARMSTRONG (NATURE, Dec. 8, p. 827) humorously appeals to me and other physicists to rush in and immerse ourselves in his aqueous difficulties, where apparently he hesitates to tread. Had FitzGerald been alive he might have been a willing victim, for he was always ready to apprehend the difficulties of others and often illuminated them by a flash of genius.

Prof. Armstrong sometimes seems more at home in an atmosphere likely to generate heat, than in the placid evolution of electricity or light; but in this instance he really does seem to want a question answered, though he does not put it very clearly. If he wishes us to enter a complex molecular assemblage, like hydrone, we may soon get out of our depth; for we know that he despises H_2O, and even H_2O is not as clearly apprehensible as we should like, in terms of atomic structure. A molecule as big as a fist would in some respects be advantageous. But what has that to do with electrical manifestations?

If we reply to Prof. Armstrong's apparent question in terms of elementary electricity, we shall be told—no doubt with perfect truth—that chemists knew all that before. Still, I will run the risk of a few platitudes. Dr. G. C. Simpson and I have both answered, publicly or privately, about the effect of aggregating small charged spheres into large ones, or vice versa; so to this I will only add that I am more disposed than is Dr. Simpson to attribute a great deal of atmospheric electricity to the influence of an outside source, namely, the sun. But Prof. Armstrong says that his point is more fundamental than that. He harps upon the need for electrodes, and constantly uses the term "circuit." I suggest that he rather over-emphasises these things. Electrodes are only necessary if the separated charges are to be conveyed to a distance by conduction: but they can travel by convection, and electrical separation can occur by displacement. Electrodes are needed for a galvanometer, not for a gold-leaf electroscope.

Examples.—A crystal of tourmaline warmed or cooled will exhibit opposite electrifications at its two ends, and if the crystal could be broken they would be separated. Pressure applied to other crystals shows a similar effect. Any conductor properly broken in an electric field will separate the electricities, just as silk rubbed on glass will exhibit electric separation when pulled apart. The same sort of thing Dr. Simpson expects in broken water drops. And certainly Armstrongs (both of the name) well know that drops of pure water propelled through a suitable nozzle will emerge electrified. In none of these cases are there electrodes, or any obvious circuit, and yet electric energy is displayed.

In a sense, it is true, there must always be a circuit of some kind. Electricity behaves rather like an incompressible fluid of which space is completely full. We cannot generate electricity; we can only separate or decompose and move apart the opposite kinds. But the circuit may be completed by insulated displacement, as well as by conduction.

The position is a little complicated by the singular and surprising fact that positive electricity is more closely identifiable with matter than the negative variety,—a prevision of which fact was intuitively grasped by Benjamin Franklin long ago. This great difference in massiveness between the two kinds of electricity enables electrical separation to go on *in vacuo*, and seems to me likely to be responsible for much of the energy of electrical separation subsequently displayed in the earth's atmosphere,—displayed most obviously when the magnetically separated entities come together again.

But what has all this to do with hydrone and water? Prof. Armstrong will not fail to notice, and probably contemn, my caution in keeping high and dry.

But now to be incautious. If Prof. Armstrong has qualms about supposing that rearrangements or combinations of H_2O in a hydrone molecule can effect electrical separation, I think those qualms are judicious; it would be too much like seeking a generation of one kind of electricity only. At the same time, if any cause can be assigned which would separate the opposite electricities of matter into different regions of a globe, an enormous amount of energy would be displayed, sufficient for ball-lightning. The quantities dealt with are prodigious. But where is such cause to be found? Could the opposite charges be centrifugalised apart? Could they, in rushing together, form a cyclone which would keep them from collapsing together for a time? The speed required, to maintain a shell of protons round a nuclear group of electrons, like a sort of inverted large-scale atom, is not unreasonable. A spherical vortex has been worked out by Prof. W. M. Hicks; what does he think of the suggestion?

I have no wish to enter the lists against the high meteorological authority of Dr. Simpson, but I do not feel that the last word has been said about the electrical energy of thunderstorms. Nor do I suppose that the last word has been said about what constitutes a chemical molecule, nor yet about hydrone.

OLIVER LODGE.

Salisbury, December 9.

Industrial Research Associations.

I HAVE read with much interest the article entitled "Industrial Science" appearing in NATURE of December 1, and I would beg to thank you for pointing out that the scheme of the Department of Scientific and Industrial Research for the establishment of Research Associations has not had a fair chance. Few could have foreseen the difficulties which it has encountered, and still fewer could realise what these actually are unless engaged in industrial operations.

As a firm believer in the ultimate success of the co-operation of science with industry, and as one who has followed closely the initial stages of one of the largest of the Research Associations, I should like to add that I am convinced that the scheme inaugurated by the Department is fundamentally a good one, and in my opinion is likely to have a very far-reaching effect, in helping our industries to face with confidence the unusual difficulties of the present situation, due no doubt in large measure to the lack of appreciation in the past of the value of science to industry.

I am aware that there are many who do not believe in the value of Research Associations, and that recently it was suggested in another journal that the "least direct way of helping industry by science is the quickest: stimulate research at existing institutions," etc. I appreciate most thoroughly the research work that is being done in the universities and similar institutions, and I am in reality most

anxious to secure the help and co-operation of these institutions, but the above suggestion, in my opinion, omits several important considerations. For example, commercial men are not very often in a position to appreciate when the difficulties of an industrial process are suitable problems for scientific research, and as a consequence many problems which should be referred to the universities for scientific help might fail to be so treated. Again, considerable knowledge both of textile processes and of the appropriate sciences is often necessary even to diagnose the cause of a defect, the solution generally requiring the co-operative efforts of the textile expert, the chemist, the physicist, and the botanist. Such qualities could scarcely be found combined in either the university professor or the industrialist.

Even assuming that these difficulties have been surmounted and the university professor is trying to solve an industrial problem, it seems that the writer of the above quotation has scarcely realised the amount of time which the university professor would have to spend in learning the conditions in which his new discoveries would have to be applied, without which information his researches, though they might be very fruitful in the accomplishment of scientific fact, would in all probability be of no real value to the industry. If, on the other hand, the university professor devoted the necessary time and thought to the solution of the industrial problems submitted to him, he might find himself with little or no time to devote to his professorial duties.

For such reasons, and from nearly four years' experience, I am satisfied that efficient co-operation between science and industry can be obtained by means of Research Associations, where highly trained scientific men will have daily intercourse with the industry, either as a whole or with the particular section of it connected with the special research problems they have in hand. In these circumstances such men may not only overcome difficulties as they arise, but, what is far more important, they will also certainly point out new lines of advance. I believe indeed that Research Associations will establish a necessary link between the universities and industry, and will be the means of stimulating the industries to take advantage of the opportunities provided.

Kenneth Lee,
Chairman.

Experiments on Alytes and Ciona.

Those who have followed this discussion may be interested in its subsequent course. I lately received the following letter, undated, from Dr. H. Przibram, director of the Versuchsanstalt, to which I have made the reply subjoined. W. Bateson.

December 2.

Vienna, XIII./7,
Hietzinger Hauptstr. 122.

My dear Professor Bateson,

Having read your offer about Kammerer's Alytes in Nature, No. 2811, my proposal is this: that you may carry out your previous intention of coming to Vienna yourself. I would gladly renew my invitation to you to spend some time at my house. Thus you would be given ample opportunity to examine the specimen without risk of its loss. It was mainly my wish to satisfy you that made me consent to Kammerer taking the specimen to England. I am sorry you have not availed yourself of this opportunity, but I could scarcely take the responsibility of entrusting the unique sample to anybody else (I had in fact declined to do so on a previous occasion, as Mr. Boulenger will affirm).

It is not probable that I shall be away from Vienna at any time before the middle of April next. At any rate, please write beforehand, when you intend coming. It would indeed be a great pleasure to see you with us.

In case you have noticed Mr. Munro Fox's letter in Nature, No. 2818, on Ciona, I would like to direct your attention to the fact that the discovery of its siphons lengthening with repeated removal was not made first by Kammerer. It was known so long ago as 1897 by Mingazzini's experiments, which were, in their turn, based on a previous observation of our friend in common, Jacques Loeb, as he mentioned to me in 1907 during my stay in California. So I do not see how Mr. Fox's inability to reproduce the experiment allows him to deny Kammerer's success with the first generation.

Believe me, dear Professor Bateson, most sincerely, your old friend, Hans Przibram.

If you think it desirable that my answer may be known in public, I would be glad if you would send this letter as it is to the editor of Nature for publication.

December 2, 1923.

Dear Dr. Przibram,

I was not without misgiving that difficulties might be raised. For that reason I offered a sum, 25*l.*, calculated to cover the railway fare, 10*l.*, of a special messenger, with a sufficient margin. I understand the obstacle is not financial, or I would gladly now double my offer.

Thank you for a most kind invitation. It would be delightful to see you all in Vienna once more, which I was prevented from doing last year. Some day I certainly hope to come, if only to look at the new marvels of the Versuchsanstalt. But as regards Dr. Kammerer's Alytes, which as it still seems to me ought to be the most convincing exhibit of all, I doubt the value of such a journey. If I were to come, and—as it might happen—return with scepticism unabated, could I do more than add one to the number of those who already have seen and yet have not believed?

In my last letter I explained how I missed making a proper examination here. Reports had varied, and I drew the inference that the nature of the black marks must be mainly a question of interpretation. Not until I saw the toad at the Linnean meeting, with the unexpected and misplaced development on the *palm of the hand*, did I discover that there was anything so positive to examine. As I thought over the incident it struck me as extraordinary that this, the real peculiarity of the specimen—which, indeed, it was set up to display—had never been mentioned by Dr. Kammerer. He left England immediately after the meeting. I might, no doubt, have been a little quicker, but in amends, and in the hope of bringing the matter to a definite issue, I made the offer, not an unfair one, which you have declined.—Yours truly,

W. Bateson.

Colour Vision and Colour Vision Theories.

In a recent letter to Nature (September 29, p. 473) Dr. Edridge-Green has condemned the colour theory of Young and Helmholtz by the sweeping statement: "There is no fact that directly supports the trichromatic theory." It is scarcely credible that such men of science as Young, Helmholtz, Maxwell, and Abney could have deliberately adopted a theory of colour vision with nothing at all to commend it.

Dr. Edridge-Green further states that I have written several papers supporting the trichromatic theory, but implies that they are included among many which though "written to support the trichromatic theory are found on examination to give facts strongly adverse to it." It is true that my papers support the theory, but the inference that they were written for that purpose is incorrect. The papers are discussions of experimental researches on the effects of fatigue of the eye, and the results, usually given in the form of persistency curves, are set forth independent of any theory. The experimental fact, disclosed by the curves, that the disturbances induced by fatigue in the eye invariably affected the red, green, and violet colours, could not in my judgment be interpreted in any other way than in support of the trichromatic theory.

Dr. Edridge-Green also quoted one sentence from one of my papers in which I refer to a difficulty arising from the visual complexity of the part of the spectrum between the wave lengths $0{\cdot}470\,\mu$ and $0{\cdot}570\,\mu$, which includes the region where the sensation curves of Abney and of König have two intersections, and those of Exner three. He states that this part of the spectrum is complex only on the trichromatic theory, while on his it is quite simple, and that my results therefore "should be as stated," or, in other words, accord with his theory. My former experiments, and more especially those very recently published, which show how colour vision in one eye is affected by reflex action arising from fatigue in the same eye and in the other, prove that the spectrum in its physiological action is exactly as complex as the sensation curves indicate it to be. I find a transition point, or, as it now seems better to term it, an equilibrium point or colour, corresponding to each of the intersections of the sensation curves. These facts are experimental, and certainly support the trichromatic theory in the most detailed and explicit manner. Indeed it was the occurrence of these complex intersections of the trichromatic sensation curves that enabled me to predict and later to discover these equilibrium colours.

The difficulty that Dr. Edridge-Green quotes from my paper regarding vision in the green has now been removed by further investigations which are described in a paper, "On Reflex Visual Sensations," recently published in the Journal of the Optical Society of America, August 1923. The solution is remarkably concordant with Prof. Peddie's conclusion contained in his recent book, which had not been published when that paper was written, and also in his letter in NATURE of October 27, p. 621, that in the visual process we have a double set of three variables, one of which arises from the internal action of the visual apparatus. This conclusion to which Prof. Peddie has come, from the interpretation of many phenomena of colour vision, accords with my own experiments on reflex sensations, though I would express it as a set of three variables acted upon by two separate and opposite stimulations, direct and reflex, the former acting to fatigue or depress the sensations, and the latter to enhance them. The double stimulation of the three sensations seems to be the necessary fundamental connecting principle in colour vision. By its employment many facts which were admittedly difficult to reconcile with the trichromatic theory are now seen to be completely in harmony with it.

By the discovery of reflex visual action upon the colour sensations it now seems possible legitimately and confidently to establish the trichromatic theory of colour vision upon the broad physiological foundations so securely laid by the researches of Sir Charles Sherrington.

FRANK ALLEN.

Department of Physics,
University of Manitoba,
Winnipeg, Canada.

PROF. PEDDIE seems to suggest that no one understands the trichromatic theory but himself. I resent his remarks in this connexion, and for this reason, unless some one else joins in the discussion, this is my final letter.

The trichromatic theory, which is very simple, has been thoroughly understood by physiologists since it was propounded. In former times most physicists, like Prof. Peddie, overlooked the physiological aspects of the question, but this is not the case with the physicists of the present day, as may be seen by the writings of Sir Oliver Lodge, Prof. A. W. Porter, Dr. Houstoun, Prof. Andrade, Dr. Troland, Dr. C. L. Martin, and others. The question is primarily one of physiology and not a mathematical problem on the functions of three variables. By physiology we are limited to one set of fundamentals for normal vision for one person. A man cannot have five and six toes on one foot at the same time. Now each set of facts requires a different set of fundamentals which makes the theory quite untenable. Let us compare, for example, the fundamentals of Abney and Burch. Abney gives the red sensation as affected by light of all wave-lengths. Burch gives the red sensation as affected by light from $\lambda 760\,\mu\mu$ to $\lambda 555\,\mu\mu$, with other points of difference. Abney gives $\lambda 548\,\mu\mu$ as stimulating the fundamentals, in sensation luminosities in the following proportions: red sensation, $49{\cdot}7$, green sensation $35{\cdot}6$, and blue sensation $0{\cdot}035$. Dr. Troland writing on the same subject, using the word minuthesis instead of fatigue, gives his results as follows:

"The general conclusion to be drawn from the work is therefore that minuthesis due to one colour does not alter the luminosity of another colour to a degree differing appreciably from that in which it is altered itself. In other words, the change in sensitivity to brightness occasioned by stimulation of the retina is independent of the wave-length constitutions of the minuthetic and of the reacting lights. This seems to imply that the luminosity function is not essentially linked with the color or chromatic function and stands in contradiction to the views of Abney, Ives, and others who treat luminosity as the sum of the primary colour values of any stimulus. The present results appear also to conflict with experimental data along similar lines published by Abney and by Burch, so that further study of the problem would seem to be required on a larger number of subjects."

These results are in a complete agreement with those of Prof. A. W. Porter and myself. (See Proceedings Royal Society, 1912, and the "Physiology of Vision," page 248.) Prof. Peddie's explanations are not explanations on the trichromatic theory: in the first he introduces a fact which can only be explained on my theory; in the second and third he gives no explanation. The positive after-image of red disappears before that for green, therefore on the trichromatic theory, if yellow be compounded of red and green, red having disappeared, the positive after-image of yellow should change to green, which it does not.

F. W. EDRIDGE-GREEN.

London, December 8.

The Optical Spectrum of Hafnium.

IN a letter to NATURE of October 27, p. 618, in which we gave a complete list of the lines belonging to the hafnium spectrum between 2500 and 3500 Å.U., we announced a detailed examination of the remaining part of the spectrum which can be obtained photographically. The result of this examination will be found in a paper, now in the press, which will appear shortly in the Math. Phys. Proceedings of the Royal Danish Academy. This paper contains

a list of all the hafnium lines (about 800) found between 7300 and 2300 Å.U., together with a detailed discussion of our methods and results. In the meantime we give here a list of the strongest lines in the region between 7300 and 3500 Å.U. Some of these lines (denoted in the table with an asterisk) have already been published at the Gothenburg meeting of Scandinavian Naturalists, where, on July 13, we presented a list of some 20 characteristic hafnium lines between 4500 and 3500 Å.U.

The spectra were produced as described in earlier letters to NATURE. In the table the lines are given to 0·01 Å.U. in international Å.U. in air, but the errors may amount to about 0·05 Å.U. In the region of the longest wave-lengths, where the accuracy is less, we give the values to 0·1 Å.U. The intensity is given both for arc and spark spectra in the usual scale (1 to 6). For the longest wave-lengths our spark spectra were not strong enough to permit us to give spark intensities, and above 5100 Å.U. the spark intensities are only of relative value and can be compared directly neither with the corresponding arc intensities nor with the spark intensities of the shorter waves.

As mentioned in our first letter (NATURE, March 10, 1923), we must expect to find some of the most prominent hafnium lines among the zirconium lines measured before hafnium was discovered, as all commercial zirconium contains from one-half to five per cent. of hafnium. In fact, we find in the region of the spectrum, for which Exner and Haschek's zirconium measurements are sufficiently exhaustive, nearly all the strong hafnium lines here given among Exner and Haschek's zirconium spark lines as weak lines of intensity 1 or 2. Since Bachem (Diss. Bonn, 1910) gives only the three lines 6386, 4093, and 3505, these lines may, until further investigations are made, be taken as the most persistent or ultimate hafnium lines in this part of the spectrum.

Scientific Names of Greek Derivation.

MAY I follow Prof. Grenville Cole (NATURE, November 17, p. 724) in supporting Sir Clifford Allbutt? The prefix "dino-," as thus spelled, is ambiguous. We who know that "dinosaur" means "terrible lizard" may smile at the undergraduate and his "dinnosaur." But how would you pronounce "Dinocystis"? Wrongly, no doubt, as I did myself until I learned that the first begetter of the name derived it from δίνειν, to swirl, because the rays are spirally coiled. The same for Dinocharis and Dinophysa. Well, then, what about the giant cork-screw shell from the Hastings Sand—the Dinocochlea of B. B. Woodward? That perhaps means "spiral coil"; or does it mean "monster coil"? Should it, in short, be Deinocochlea or Dinocochlea?

We may, in systematic nomenclature, feel bound by the rules for transliteration recommended by one or other international committee; but in writing English let us be free. Alas! here comes the Society for Pure English with its Tract XIII., and invites us to print "coeval," "medieval," "primeval," and "peony." Why? If you eliminate the bouquet of the grape, the wine may be the purer, but it tastes no better. Already you may hear others than undergraduates speak of ĕconomics and ĕcological. These changes of spelling do not follow the debased pronunciation, they induce it; and so the meaning and force of words vanishes with their savour. Pure English indeed! Fortunately some impure English, called slang, still has "a tongue with a tang."

Next Prof. Cole deals with the writing and printing of diphthongs. The British Museum, he reminds us, writes "Moeritherium." That is because the officers of its Geological Department and others long since discovered that the use of digraphs (œ, æ, etc.) to represent diphthongs was the most fruitful source of misprints. Let us help the printers and our pockets! Otherwise I foresee the day when the undergraduate will call "this fascinating creature" the Merrytherium.

F. A. BATHER.

LIKE Prof. Cole (NATURE, November 17, p. 724) I prefer to transliterate the Greek letters, especially the vowels and diphthongs, directly into English—to represent, for example, αι by *ai* instead of *æ*, and ει by *ei* instead of *i*. Perhaps the worst examples I know of the emasculation of Greek diphthongs are the old-established Miocene and Pliocene, which show not only a weakening of ει to *i*, but also a further degradation of αι to a simple *e*. I am afraid it is too late to restore these words; but I am sorry to say that there are those who, on the specious plea of consistency, wish to write Cenozoic for Kainozoic and to extend this system of transliteration indefinitely. What this means is illustrated by the fate of the two words καινός and κενός, both represented by "ceno-," which in Cenozoic and Cenocrinus means "recent," and in Cenoceras and Cenosphæra means "empty," a most unnecessary and unreasonable confusion of distinct words.

JOHN W. EVANS.

An Uncommon Type of Cloud.

THE type of cloud photographed by Dr. Lockyer (NATURE, November 17, p. 725) is very frequently seen at Kodaikanal in south India during the thunderstorm season in April and May. It is always associated with thunder and always appears after the thunder clouds have expended their electrical energy. This often happens quite suddenly when the storm is of local origin.

On one occasion when developing a photographic plate at the Observatory I received a slight shock from a lightning discharge nearby, or more probably from an induced charge in the lead lining of the developing table. Since then I have hesitated to go up to the Observatory during thunderstorms, and have been accustomed to look out for the "all clear" signal which these mammato-cumulus clouds give us.

Another remarkable fact connected with local thunderstorms at Kodaikanal, and probably elsewhere, is the curious roaring sound emanating from the cloud before a storm begins. At first I considered this was due to heavy rain approaching, but concluded that this could not be so. The situation at Kodaikanal is such that one may find oneself very near to a cloud mass rising over the steep sides of the mountains, and the sound always appears to come from the cloud itself, and not from the ground or from trees. Possibly Dr. Simpson can explain this; he would probably have heard it at Simla.

Consumption of Fish by Porpoises.

IN the course of our cruises, we have often harpooned porpoises of various species, and occasionally investigated the contents of the stomach. Sometimes the stomach was found to be empty, but in most cases it contained remains of fish, though these were, as a rule, so decomposed by the digestive fluids that identification was impossible. Now and again, however, it could be done. In the vicinity of the Continental Slope, for example, west of the English Channel, where porpoises are nearly always found in abundance, we found great bundles of the pelagic pipe-fish, *Entelurus æquoreus* L., in the stomachs of porpoises taken. But as a rule, the porpoise evidently prefers fish of somewhat more fleshy build than the pipe-fish.

The present note is occasioned by the recent preliminary investigation of a sample from one of the cruises of the *Thor*. On June 24, 1910, being then off the south coast of Spain, in the Mediterranean (between 36° 10′ N., 4° 42′ W., and 36° 19′ N., 4° 0·6′ W.), we harpooned a female specimen of the common long-nosed porpoise (*Delphinus delphis* L.). The stomach contents consisted of fish-residue: more or less dissolved soft parts, crumbling backbones, otoliths, and eye-lenses. I noted that most of the fish-bones were green, but no identification was attempted. The most interesting feature was the great number of otoliths, or ear-bones, of fish. When these were sorted out and counted, there were no fewer than 15,191 of different sizes, though mostly small. Several species were represented, about five; but, owing to lack of material for comparison, I cannot give any further determination at present. Some are presumably those of Scomberesox, clupeoids and scomberoids, possibly also scopelids.

The sample is interesting, inasmuch as it gives some slight idea of the porpoise's enormous consumption of fish: in the stomach of this one specimen we found remains of no fewer than 7596 fish. How long the porpoise took to collect the whole 7596 it is impossible to say, since we do not know how long the otoliths remain in the stomach before being dissolved or passed out. The fact that otoliths are not always found in the stomachs of porpoises seems rather to suggest that they do not remain there very long.

JOHS. SCHMIDT.

Crystallisation of Cementite in Steel.

WITH reference to the particularly interesting article by H. C. H. C. in NATURE of November 17, p. 728, might I mention the following amongst many other examples which have come under my notice illustrating the tendency of cementite to form cell walls or a network under conditions where the occurrence of pearlite is more commonly anticipated? In dead mild steels the occurrence of cementite in either network or comparatively massive formation has been recognised by a number of investigators. Fig. 1 illustrates an exceptional case in which isolated cell walls were found only near the edge of a dead mild-steel plate, in a region otherwise microscopically carbonless. The only apparent explanation of this occurrence was that the plate must have become carburised locally during the processes of manufacture.

FIG. 1.—Cementite network in mild steel. × 300.

FIG. 2.—Cementite in ferrite grain junctions, in nickel steel. × 1500.

In the alloy steels, the simultaneous occurrence of structurally free ferrite and juxtaposed carbide network would be regarded as uncommon, but Fig. 2 shows an instance of this occurrence in a large oil-hardened nickel-steel forging. At the magnification of 2500 with which the original photograph was taken by means of the super-microscope, the carbon-containing constituent can readily be seen to be lamellar pearlite, which makes easy the identification of the carbide plates in the ferrite boundaries.

Minute "Organisms" isolated from the Virus of Mosaic Disease of Tomato.

The nature of the infective principle in plants suffering from mosaic disease is obscure, although most recent workers favour the view that it is a living organism. Allard and Duggar have emphasised the minuteness of the causal agent, whilst Matz, Kunkel, Nelson, and others have described protozoan-like bodies in the cells of affected plants.

A considerable amount of work has been done on this problem at Cheshunt, and the present note records the isolation and growth in pure culture of a minute "organism" from the filtered virus of tomato mosaic.

Isolations were made from affected plants by a modification of Noguchi's method. Tubes of sterile extract of tomato stem and leaf (100 gm. fresh material to 1000 cc. distilled water) were prepared, and into each was dropped a small piece of living tomato tissue cut, under aseptic conditions, from the interior of healthy green fruits. Ten tubes were inoculated by touching the tomato tissue under the liquid with a loopful of tomato virus filtered aseptically through a sterile Doulton candle. Ten uninoculated tubes were left as controls. All tubes were incubated in a Bulloch's anaerobic jar for two months, and on removal were found to be clear. The tubes were then left under ordinary atmospheric conditions, and two months later one tube was contaminated by a fungal growth, but the liquid in the remaining nineteen was quite clear in both the inoculated and the control tubes. This liquid was examined for micro-organisms by plating and streaking upon different culture media, but no growth was observed. On the glass, however, of each of the original inoculated tubes about one centimetre above the liquid were small brown bodies, the largest of which was 200μ in diameter. No such bodies were present in the controls.

These bodies were tightly fixed to the glass, and not easily detached. They are brittle and break into fragments of a crystalline appearance. The bodies are discoid convex, and when stained with borax carmine the surface shows concentric and radiating markings. They clear in acid with evolution of gas, the cleared bodies having a fine granular appearance. When stained by Giemsa's method they resemble bacterial colonies, containing deeply stained purple granules standing out distinctly on a stained background. These granules are 0·3 to 0·4μ in diameter (occasionally smaller granules are seen) and appear as cocci, diplococci, polar bodies, or unstained rods. These are not merely crystals or detritus but definitely organised bodies growing in colony formation. Distinctive preparations have been made by staining with Giemsa for 24 hours and then differentiating with absolute alcohol. The granules are best seen in smears made from the cleared colonies prior to fixation by drying.

Tubes of virus kept in the laboratory for six to eighteen months under aerobic conditions revealed similar colonies on the glass in those tubes where no toluene had been added for preservative purposes or from which the toluene had disappeared. After acid clearing and staining, the minute granules were readily demonstrated. Films made from the clear liquid in the tubes bearing the colonies were also stained with Giemsa, and purple-stained granules similar to those so abundant in the colonies were regularly found in these preparations. They were not numerous, five or six only being seen in a single field, and appearing as cocci or as diplococci.

Continued cultivation of the "organism" has been maintained in tubes of tomato extract containing cubes of sterile raw tissue. (The addition of 0·3 gm. calcium carbonate to 10 c.c. of extract hastens the production of colonies. Increased concentration of carbon dioxide in the atmosphere also seems to assist in the formation of colonies and alters their appearance; the brown colonies becoming white and chalky.) Numerous media have been inoculated with negative results, but one inoculation is especially interesting. A flask of lemco gelatine containing a high proportion of gelatine was inoculated with a drop from one of the original culture tubes. No growth was apparent for four months, but after six months the surface was covered with minute hard white bodies, which on examination proved to be similar to those described. Colonies transferred to Noguchi tubes dissolved in the liquid, and films prepared from this ten days later showed the presence of minute granules either singly as diplococci or as aggregates in alveolar plasmodium-like structures in which cocci stood out deeply stained in comparison with the faintly stained matrix.

The bodies forming on the glass of Noguchi tubes and in the liquid, and the lemco colonies, have been inoculated into healthy plants under various conditions; and while there are indications that they may be causally related to mosaic disease, no definite claim can yet be made. The presence of these "organisms" in the virus of tomato plants suffering from mosaic, and their very interesting nature, appear, however, of sufficient importance to warrant the immediate direction of the attention of workers on this difficult problem to their existence. A detailed investigation of the character and genetic relationships of the "organisms" recorded in this note and their relation to mosaic disease is being carried out at Cheshunt. W. F. Bewley.

Globular Lightning.

Your correspondent, Mr. E. Kilburn Scott, suggests in Nature of November 24, p. 760, that "the ball may be a mass of concentrated nitrogen oxides," and considers that this would "fit in well with the formation and action of such gases," and he compares the chemical activity of lightning with the well-known reactions occurring in high-tension arc flames.

Although I do not wish to be understood as expressing any opinion regarding "globular" lightning, I should like to point out that in the letter which appeared in Nature of September 15, p. 396, I produced evidence in connexion with the extremely vivid and prolonged thunderstorm of July 10, 1923, which left no doubt that the chemical changes that occurred then resembled those of the silent electric discharge, rather than high-tension arc flames, because, although there was no increase in the proportion of the oxides of nitrogen in the air within the area of the storm, there was a very great increase in the proportion of ozone.

I may add that since the proportion of nitrogen peroxide is always much higher in London than in country air, and is considerably greater in winter than in summer, we may look, as in the case of sulphur dioxide, to combustion of coal as the probable source of most of it at least. The seasonal changes of the curves for these two variable ingredients of the atmosphere are very similar, and are not in any way related to that for ozone. William C. Reynolds.

Rejuvenescence and the Testicular Graft.

By Dr. F. H. A. MARSHALL, F.R.S.

IT has been known from very early times that castration in both man and animals, besides causing the suppression of the sexual instinct, produces marked changes in the bodily conformation and the secondary characters of sex, and that these effects are far more definite if the operation be performed before puberty. There are numerous references to the subject in the works of Aristotle, who remarks on the immense modifications in the general configuration brought about by the mutilation of a comparatively minute organ. The abnormal height of the eunuch, his undeveloped larynx and soprano voice, and the absence of hair on the face and other parts of the body where it is usually present in men are among the well-known effects of testicular deprivation. The domestic animals also furnish striking examples of the consequences of castration, and the same may be said about birds. Thus the testes, besides being responsible for the development of the sexual instinct, are an essential factor in the formation of the bodily characters associated with maleness. The manner in which this influence is exerted, however, has only comparatively recently been ascertained, and there are still many gaps in our knowledge.

According to Berman, the author of "The Glands regulating Human Personality," the first to conceive the idea that the gonads exert their effect through an internal secretion poured into the blood was Bordeu, who was Court Physician to Louis XV. in the eighteenth century. Berthold, however, in 1849 was the earliest to base the idea on experimental proof. This investigator removed the testes from cocks and transplanted them into new positions in the body, and he noted that the birds developed or retained their male characteristics (voice, sexual and combative instincts, growth of comb, wattle, etc.) just as though they were normal males. These results were attributed by Berthold to substances formed by the testes irrespective of their position, and thus he was the first to put on a definite experimental basis the idea of an organ elaborating a hormone which, after being carried in the circulation, acted upon other and distant parts of the body. Little account was taken of Berthold's work at the time, and it was not until much later that the conception of organs having an endocrine function was revived by Claude Bernard, who applied it to the liver. In recent times Berthold's work on the testicular graft has been confirmed for a large number of animals, and the fact that the testis, in addition to producing the semen, gives rise also to one or more chemical substances of the nature of hormones has been established.

The notion that the testis produces an internal secretion which, besides being responsible for the male characters, possesses also a rejuvenating influence, is a somewhat different one. It was originally put forward in 1889 by Brown-Séquard, who injected testicular extract, first into animals and then into himself. He was convinced that in both cases beneficial effects accrued, and claimed that he himself underwent a radical change and regained the force and vitality of former years. The extracts were made from dogs' and guinea-pigs' testes, and were injected subcutaneously. At this time, Brown-Séquard was seventy-two years old. The supposed rejuvenating effects, however, did not last, and although this form of treatment was extended to some hundreds of patients suffering from various diseases (rheumatism, sciatica, locomotor ataxia, tuberculosis, etc.) by Brown-Séquard and Brainard, who claimed that good results often followed, the practice of testicular injection was soon discontinued and became generally discredited.

In recent years, however, the idea of testicular rejuvenation has been revived in connexion with grafting experiments. In 1913, Lespinasse, an American doctor, recorded a case of testicular transplantation in a man, but gave no evidence of the persistence of the graft beyond that afforded by sexual potency. About the same time Lydston, of Chicago, is reported to have done similar work with human grafts, and the medical department of the California State Prison is said to have organised transplantation experiments in which testicles obtained from executed criminals were grafted on to senile individuals, but there is no satisfactory evidence as to the results obtained.

More recently (1918) Stanley and Kelker have performed the same operation, and in further experiments the testes of animals were substituted for human ones. It was believed, however, that in all cases the grafts became necrotic and were either absorbed or else the site of operation opened up and the necrotic material was discharged. In a later paper, Stanley has described a large number of experiments (more than 1000 had been carried out by 1922) in which men were injected with partially macerated testis by a syringe. With this method the danger of sloughing was much reduced, and the injected substance could be felt under the skin for months, but it was eventually absorbed. From these experiments Stanley concluded that animal testicular substance injected into the human body caused decided benefit for some time. Among those treated were patients suffering from neurasthenia, epilepsy, asthma, tuberculosis, diabetes, and many other chronic diseases, as well as senile decay. Most of the subjects reported increased sexual activity and resumption of virility where this had been lost. It is said, further, that testicular substance often has a beneficial effect in relieving pain of unknown origin and in promoting bodily well-being, and that the power of vision is sometimes greatly strengthened. The testicles used were those of goats, rams, deer and boars.

Three cases have been described by Lyons in which rams' testicles were transplanted on to men suffering from debility and impotence, and in two of these favourable results were claimed, but the fate of the grafts was unknown.

The above recorded experiments were all carried out in America in the last decade. In the same period, numerous operations of a similar order have been carried out in Europe. In 1915, Lichtenstern, of Vienna, operated on a soldier who had lost his testicles as a result of being wounded in the War. After a few months, the patient showed all the usual signs of

complete castration and suffered from want of vigour and general apathy. Lichtenstern then engrafted an undescended testicle from another individual, and as a consequence the symptoms of castration disappeared and the man became normal. Two and a half years later he was still normal, having been married fifteen months. Further cases of testicular transplantation in men are recorded by Lichtenstern as well as by Kreuter and Mühsam, the operation being performed for eunuchoidism and homosexuality, as well as for debility and impotence, and successful results are claimed. In none of these cases does there appear to be definite evidence as to the fate of the graft, but it would appear almost certain that it must have persisted for some time.

Voronoff, whose work on the so-called "monkey gland" has attracted so much attention, began his experiments on the testicular graft at the Collège de France in 1917. His earlier work was upon sheep and goats, in which he grafted young testes into old animals and into animals castrated before puberty. The best results were obtained by grafting the testes into the scrotal sacs, or in the case of aged animals, upon the testes already present. Retterer and Voronoff, in a paper published last summer, tell us that some of these animals are still under observation at the Laboratory of Experimental Surgery of the College and that they continue to display sexual vigour and ability to copulate. The success attending these experiments led Voronoff to attempt testicular transplantation upon aged men. In connexion with this work, two points are strongly emphasised; first, the advantage of making the graft in a suitable position and preferably the natural position of the organ; and secondly, the importance of biological affinity between the individual from which the testis is taken and the recipient of the graft; consequently, in carrying out testicular transplantation from animals to men, Voronoff selected the chimpanzee as the most suitable animal from which to obtain the graft, since of all the anthropoid apes this species is believed to be the nearest akin to man. The result of the operation in many instances is claimed to be entirely successful. The walls of the arteries are said to have become softened and the capacity for work increased, and, in short, a complete restoration of mental and muscular vigour is stated to have been attained. In the majority of men so operated upon sexual potency also is said to have been revived.

In some of Voronoff's experiments there is definite evidence concerning the persistence of the graft, and Retterer and Voronoff have described microscopic sections of graft tissue after several months of transplantation. Thus the figure of a section of a goat's testis a year after grafting shows cells which might reasonably be supposed to have had an internally secreting function, though the tissue as a whole had undergone considerable degeneration and neither spermatozoa nor interstitial cells can be detected. The authors state that the condition of the transplanted chimpanzee's testis is similar, but they do not appear to have recorded the duration of the graft. On the other hand, Thorek, an American surgeon, who has recently confirmed Voronoff in regard to the persistence and efficacy of the chimpanzee graft when made upon man, has described and supplied photographs of sections of such grafts when removed four months after transplantation, and these show an abundance of secretory cells and every evidence of active life, though the seminiferous tubules had undergone incomplete regression. The good results are attributed to a new technique whereby the vascularisation of the graft was greatly improved.

There is one point of importance on which Retterer and Voronoff differ from most physiologists, and this relates to the elements which are responsible for producing the internal testicular secretion. The bulk of the experimental evidence is strongly in favour of the view that the testicular hormone is elaborated by the interseminiferous or interstitial cells, and Steinach, who has called this tissue the "puberty gland," attributes the supposed rejuvenating effects of vasectomy to the hypertrophy of this gland, pointing out that the spermatogenetic tissue after this operation undergoes degeneration as noted by former observers. According to the French investigators, however, the testicular graft does not contain interstitial cells, the rejuvenating function being due to the epithelial cells which continue to discharge the problematical secretion into the circulation notwithstanding the fact that they become converted by poverty of nutrition into "young connective tissue." On the other hand, in Thorek's preparations, the interstitial cells have proliferated and appear to have been functionally active.

In conclusion, it must be emphasised that the work is as yet in the experimental stage. In many of the cases recorded the effects of "suggestion" are not satisfactorily excluded, and the evidence as to the persistence of a functional graft is still meagre. That the histological results are conflicting and that those of Voronoff are contrary to the usual view as to the source of origin of the hormone, are valid reasons for reserving judgment. Nevertheless, it must be pointed out that the accumulation of evidence in support of the contention that a testicular graft obtained from another individual, and even from another species, may exert a definite physiological influence upon the recipient, is considerably greater than many men of science have so far been disposed to admit.

Some Aspects of the Physical Chemistry of Interfaces.[1]

By Prof. F. G. DONNAN, C.B.E., F.R.S.

LET us now inquire how far the phenomena which are characteristic of a gas-liquid interface occur also at the interface between two immiscible or partially miscible liquids. Many years ago it was shown by Gad and by Quincke that a fatty oil (such as olive oil) is very readily dispersed in the form of an emulsion by a dilute solution of caustic soda. Some experiments which I once made showed that a neutral hydrocarbon oil could be similarly emulsified in a dilute aqueous solution of alkali if one of the higher fatty acids was dissolved in it, whilst the lower fatty acids do not

[1] Continued from p. 870.

produce a similar action. It was shown that the action runs parallel to the lowering of interfacial tension and must be ascribed to the formation of a soap, which lowers the interfacial tension and concentrates at the interface. These phenomena have been further investigated by S. A. Shorter and S. Ellingsworth, by H. Hartridge and R. A. Peters, and by others.

If a substance which is dissolved in one liquid A, and is practically insoluble in another liquid B, is found to have, in very dilute solutions, a strong effect in lowering the tension at the interface A-B, the following interesting questions arise:

(1) What is the amount of the surface concentration or adsorption per sq. cm. of interface?

(2) Can it be calculated by means of the simplified Gibbs equation?

(3) How does the surface adsorption vary with the concentration?

(4) Does the "saturation" value correspond to the formation of a unimolecular layer?

Some of these questions were experimentally investigated in my laboratory by W. C. McC. Lewis. For the liquid A water was chosen, and for B a neutral hydrocarbon oil. Working with sodium glycocholate as the surface-active substance, it was found that the experimentally measured surface adsorption q was much greater than that calculated by means of the equation

$$q = -\frac{c d\gamma}{\mathrm{RT} dc}.$$

Comparing the values with those previously obtained for the air-liquid surface, it is clear we are not dealing with simple unimolecular layers, but with adsorption layers or films many molecules thick. On the other hand, if we calculate from Lewis's results the surface area per molecule as deduced from the surface tension measurements by the simplified Gibbs formula, we arrive at values which are consistent with the gradual building up of a unimolecular layer (of possibly heavily hydrated molecules or micelles). It is possible, therefore, that the Gibbs equation gives the surface concentration of the primary unimolecular "two dimensional" surface phase, and that any building up of further concentrations beyond this layer does not affect the surface tension. In a later investigation Lewis determined the surface adsorption of aniline at the interface mercury-aqueous alcoholic solution, and found in this case a very fair agreement between the observed and calculated results. This case is more favourable, since we can be in little doubt concerning the molecular weight of the solute units. We may conclude, therefore, that Lewis's measurements in this case point to the building up of a primary unimolecular layer, unaccompanied by any further concentration or "condensation" of molecules or colloidal micelles.

Experiments similar to those of Lewis have been very recently made by E. L. Griffin, who has measured directly the adsorption of soaps from aqueous solutions at a mineral oil-water interface. The results obtained are as follows:

Substance.	Average Surface per Molecule adsorbed.
Sodium Oleate	48×10^{-16} sq. cm.
Potassium Stearate	27×10^{-16} sq. cm.
Potassium Palmitate	30×10^{-16} sq. cm.

These figures are very interesting, for they would appear to indicate the formation of unimolecular surface layers.

We have seen that in the case of the air-water surface there exists an electrical separation or potential difference in the surface layer, and that certain substances can produce pronounced variations, or even reversals in sign, of this electrical double layer. It becomes a matter, therefore, of great interest to inquire whether similar phenomena occur at the interface between two immiscible liquids, and, if so, to ascertain whether such electrical charges or double layers bear any relation to the "stability" of pure emulsions, or fine dispersions of one liquid in another. It is well known that those disperse or finely heterogeneous states of matter known as colloidal solutions depend in part for their stability on the existence of such electrical potential differences. We might expect, therefore, that an investigation of these emulsion systems would throw some light on the general theory of what are called "suspensoid" or "lyophobic" colloidal states.

Investigations with these objects in view were carried out some years ago in my laboratory by R. Ellis and F. Powis. The method employed was to measure directly by means of a microscope the motion of minute globules (suspended in water) under the influence of a known electric field. From the measured velocity and potential gradient, the interfacial P.D. and the electrical charge can be calculated from the theories of Helmholtz, Lamb, and Stokes. The microscopic method has the advantage that the P.D. between the aqueous solution and the glass wall (cover glass or object glass) can be determined simultaneously. It is a remarkable fact that the P.D. between various types of hydrocarbon oils (purified from acid so far as possible) and water was found to be 0·045-0·053 volt, the oil being negative—that is to say, the oil droplet moving towards the anode. If we compare this with the value recently calculated by McTaggart for the P.D. between an air-bubble and water (deduced from a precisely similar type of measurement), namely 0·055 volt, we can draw the conclusion that the potential difference is due to an electric double layer residing in *the surface layer of the water*. The oil droplet moves, therefore, with an attached negative layer or surface sheet, probably determined by hydroxyl ions, this being balanced by a positive layer the charge of which is determined by hydrogen ions.

Perhaps the most remarkable result which has emerged from these electrical investigations of oil suspensions is the relation between the stability of the emulsion and the potential difference of the interfacial double layer. The minute oil globules are in constant Brownian motion and must frequently collide. Why do the forces of cohesion not produce agglomeration or coalescence (coagulation or clearing of the emulsion)? At distances great in comparison with their own dimensions the electric double layers will act practically as closed systems. But when two oil drops approach sufficiently near each other the conditions will be different, since we must expect a repulsive force when two similarly charged outer layers just begin to interpenetrate each other. Hence the answer to the question asked above is that the third factor is the potential difference or electric density of the interfacial double

layer. Other things being equal, the probability P of an encounter leading to coherence will be a diminishing function of the electric intensity π of the similarly constituted double layers, *i.e.* $dP/d\pi$ will be negative. Hence, of the total number of encounters in a given small period of time, the number which lead to coherence should be a maximum at the point of zero potential difference (iso-electric point of Hardy).

Now the experiments of Powis brought out the very important fact that when the interfacial P.D. (whether positive or negative) is above a certain value, which was about 0·03 volt for his conditions, the rate of coagulation or coherence of the oil drops is relatively small, but rapidly increases when the P.D. falls inside the zone $-0{\cdot}03$ $+0{\cdot}03$ volt. Under definite conditions there exist, therefore, what we may, speaking broadly, call a *critical potential* and a *critical potential zone.* When the P.D. is outside this zone the emulsion is comparatively very "stable." Very small concentrations of electrolytes, which, as we have seen, increase the P.D., increase this stability. As soon as the concentration of any electrolyte is sufficient to bring the P.D. into the critical zone, the stability of the emulsion undergoes a sudden and very marked decrease, and relatively rapid coagulation occurs. Take, for example, the case of thorium chloride. On increasing the concentration we find that the interfacial P.D. traverses successively the following regions:

(1) Above the critical value (and negative).
(2) Inside the critical zone (negative and positive).
(3) Above the critical value (and positive).
(4) Below the critical value (and positive).

In exact correspondence with this series we find that the emulsion goes through the following states:

(1) Stable (oil particles "negative").
(2) Unstable and flocculating (oil particles negative or positive).
(3) Stable (oil particles positive).
(4) Unstable and flocculating (oil particles positive).

Here we see a very striking analogue and explanation of the phenomena observed by Joly in studying the effect of aluminium salts on the sedimentation of clays, and of the numerous examples of the so-called "irregular series" observed in the flocculation of suspensoid hydrosols by salts with polyvalent cations.

As Linder and Picton showed, when two suspensoid hydrosols, one negative and the other positive, are mixed, then, depending on the ratio, a stable hydrosol (either positive or negative) can be obtained. In continuation of this work, W. Biltz demonstrated the existence in such cases of a "zone of coagulation," *i.e.* a zone of concentration ratios leading to coagulation. A study of the mutual behaviour of a negative oil emulsion and the positively charged ferric oxide hydrosol provides a complete explanation of this curious phenomenon. When increasing amounts of the iron oxide hydrosol are added to the oil emulsion, it is found that the interfacial P.D. falls to zero, and then reverses its sign, becoming increasingly positive—an action which is due to the adsorption of the positively charged micelles at the oil-water interface. When the P.D. is above a certain value (positive or negative) the system is stable. But within the critical zone a rapid and relatively complete mutual coagulation takes place.

These studies of oil emulsions (and of the glass-water interface), by means of the micro-cataphoresis method, have thrown a great deal of light on many previously ill-understood points in the theory of colloids. The following table contains the concentrations (in millimols per litre) of certain electrolytes required to reduce the potential of a certain hydrocarbon oil emulsion from its "natural" value (against pure water) of 0·046 volt to the critical value, 0·03 volt:

——	Concentrations.	Ratios of Concentrations.
KCl	51	2500
$BaCl_2$	1·9	95
$AlCl_3$	0·020	1
$ThCl_4$	0·0070	0·35

These results show the enormous influence of the valency of the cation in a series of salts with the same univalent anion, and explain in a striking manner the analogous effects in the coagulation of lyophobic hydrosols. The exact value of the critical potential and the range of the critical zone will depend, of course, on the experimental definition of "rapid coagulation," and on the concentration, nature, and degree of dispersion of the hydrosol. It is not to be supposed, therefore, that these critical values are constants except under very definite conditions. The fundamental fact is that under given conditions the rate of coagulation of the particles of an oil suspension or of a lyophobic hydrosol undergoes a relatively sudden and very great increase when the interfacial P.D. falls below a certain finite value (positive or negative).

In discussing the "stabilities" of hydrocarbon oil emulsions, it must not be forgotten that I was dealing with very dilute *suspensions* of oil in water, produced by mechanical agitation without the addition of any "emulsifier." I pointed out that in the emulsification of oils in water by means of soap, the soap lowers the interfacial tension and concentrates at the interface. When we wish to produce oil emulsions in the ordinary sense of the term, we must use some such emulsifying agent, and for this purpose many substances are employed, such as soap, gum acacia, gelatin, casein, starch, etc., etc. All these substances concentrate or condense on the surfaces of the oil globules. If we may regard these surface films as very mobile from the molecular-kinetic point of view, it is clear that they will confer an increased degree of stability on the emulsion.

It is probable, however, that the stability of the emulsion is in many cases due to the fact that the surface films possess a very viscous, quasi-rigid, or gel-like character, so that a more mechanical explanation is necessary. As S. U. Pickering showed, oils may be emulsified in water by the gels of certain basic salts; and A. U. M. Schlaepfer has shown that emulsions of water in kerosene oil may be obtained by means of finely divided "carbon." Nevertheless, even in cases where an emulsifier is used, we may hope to succeed in obtaining a more precise physical analysis of the system. It is interesting in this connexion to note that Mr. W. Pohl has recently found in my laboratory that when a neutral hydrocarbon oil is emulsified in

water by means of sodium oleate, the electrical potential difference at the oil-water interface is almost doubled, and that the effects of alkalies and salts on this potential difference are very similar to those found in the case where no emulsifier is employed.

I cannot conclude this account of certain aspects of surface actions and properties without making a passing, though all too brief, reference to the beautiful investigations of Sir George Beilby on the amorphous layer. He has shown that when the surface of crystalline matter is subjected to shearing stress there is produced a surface layer of a vitreous or amorphous character—a "flowed" surface—in which the particular ordered arrangement of the molecules or atoms which is characteristic of the crystalline matter largely disappears. Working at University College, London, Dr. Travers and Mr. R. C. Ray have recently obtained a very interesting confirmation of the Beilby effect. The heats of solution (in kilogram calories per gram mol) of vitreous silica and silver sand (silica as crystalline quartz) in aqueous hydrofluoric acid were found to be 37·24 and 30·29 respectively. After grinding for fifteen hours the corresponding values were 36·95 and 32·46 respectively. If we assume that the internal energy of the amorphous phase produced by grinding is the same as that of the vitreous silica (silica glass), we can calculate from these results that about 31 per cent. of the crystalline silica has been converted by grinding into "amorphous" silica. The densities of silica glass and silver sand were found to be 2·208 and 2·638 respectively. After fifteen hours' grinding the density of the latter was lowered to 2·528. On the same assumption as before, it follows that about 26 per cent. of the quartz has been converted into the vitreous condition. The difference between the figures 31 and 26 is doubtless due to the approximate character of the assumption underlying the calculations and to experimental errors. There seems little doubt, however, about the soundness of the main conclusion—namely, that the mechanical action of shearing stress on crystalline matter is to produce a random molecular or atomic distribution in the surface layers.

Obituary.

Mr. J. M. Wilkie.

Mr. John Matthew Wilkie died on November 29 after an operation. He was born at Montrose in 1876, and was educated as a pharmaceutical chemist; after passing his minor in Edinburgh he went to Derby and later to London. In 1900 he was appointed as an assistant analyst, and eventually deputy chief analyst, in the laboratory of Boots Pure Drug Co., where he remained until his death.

Perhaps the best known of Mr. Wilkie's researches were the estimation of small quantities of lead, published with Mr. Harvey, the silver methods for the determination of phosphoric acid, and the alkaline iodine oxidation of phenols, the last two researches being published in the journal of the Society of Chemical Industry. He also devised a most ingenious method for the estimation of sulphur and oxidised sulphur compounds, which depended on the formation of acid by the bromine oxidation, but this research has only been published in abstract, as he was never quite satisfied that he brought it to a satisfactory completion. These sulphur oxidation methods have, however, been in use at Messrs. Boots' laboratory for some years with most satisfactory results. The last four years of his life was devoted to an almost monumental research on the determination of minimal quantities of arsenic. Step by step he patiently investigated the points of the method, and at the time of his death his work was concluded, and he was engaged in putting his notes into order for publication. This research was given to the world in abstract at the joint meeting of the Society of Public Analysts with the Nottingham Section of the Society of Chemical Industry at Nottingham on January 17 last.

As secretary to the Nottingham Section of the latter society from 1914 to the present year, he was largely responsible for the success of that Section and the great increase in the membership. He had just become chairman of the Section, and, although he had only presided at one meeting, he signalised that by inaugurating a discussion in which a large number of young members were persuaded to take part. It was always Wilkie's policy to encourage and bring forward young talent, so much so that at Mrs. Wilkie's special request he was borne to his last resting-place by the young men that he used to encourage and talk about so often.

The issue of *Science* of November 23 contains an appreciative account, by "H. H. W.," of the life and work of Prof. Robert Wiedersheim, the distinguished professor of anatomy in the University of Freiburg, who died on July 12. Wiedersheim was born on April 21, 1848, at Nürtingen-am-Neckar, and went in succession to the Universities of Tübingen and Würzburg. At Würtzburg he obtained his M.D. and became assistant professor under Köllicker (1872–76). In 1876 he went to Freiburg as assistant to Prof. Alexander Ecker, whom he succeeded as professor of anatomy in 1887. This post he held until he retired from active work in 1918. Wiedersheim's work lay in the fields of human and comparative anatomy. In 1882 he published his "Lehrbuch der vergleichenden Anatomie der Wirbeltiere," following up this work with the "Grundriss der vergleichenden Anatomie," covering the same ground in a more concise manner. The last edition of the latter, the seventh, appeared in 1909. A modified translation of the "Grundriss," by Prof. W. N. Parker, was published in 1886 by Messrs. Macmillan and Co., Ltd. He also published a number of monographs, among which "Das Kopfskelet der Urodelen," that on the ear of the Ascalaboten, the anatomy of *Salamandrina perspicillata* and *Geotriton fuscus* are best known. With his death an outstanding figure in the history of the comparative anatomy of vertebrates has passed away.

We regret to announce the following deaths:

Mr. George Wharton James, of Pasadena, California, known for his work on American Indian ethnology, on November 8, aged sixty-five.

Prof. H. Freeman Stecker, professor of mathematics in the Pennsylvania State College, a worker in non-Euclidean geometry, on October 30, aged fifty-six.

Current Topics and Events.

DR. G. D. LIVEING, who reaches his ninety-sixth birthday on Friday, December 21, may be assured that, in addition to the many personal friends who offer him congratulations on the maintenance of activity and intellectual interest at so great an age, chemists and other men of science, not only in Great Britain but also abroad, think of him with affection and esteem. He has had a remarkable life, and his contributions to scientific knowledge will long remain a permanent testimony to his care in experiment and caution in conclusion. Dr. Liveing went to St. John's College, Cambridge, was eleventh Wrangler in 1850, and in the following year was placed at the top of Class I. in the newly instituted Natural Sciences Tripos. He was elected to a fellowship at St. John's College in 1853, and became professor of chemistry in the University in 1861, a post which he filled until 1908. His name will always be associated with the growth and development of the Chemical Laboratories of the University. In 1879, Dr. Liveing was elected a fellow of the Royal Society, of which he was vice-president for two periods, 1891–2 and 1903–4. He was awarded the Davy medal in 1901 for his contributions to spectroscopy, and in making the presentation, the president of the Royal Society referred to Liveing's work as "one of the most valuable contributions to this department of chemical physics yet made by British workers." The work on spectroscopy was given to the world in numerous papers in the Proceedings of the Royal Society and the Cambridge Philosophical Society, and was brought together in 1915, in collaboration with the late Sir James Dewar, under the title "Collected Papers on Spectroscopy." Dr. Liveing holds the unique distinction of having been in residence at Cambridge for more than seventy-five years in unbroken succession, and his figure is probably well known to most living members of the University.

PROF. KLEINE of Berlin, who has just returned to Europe, has been investigating the therapeutic properties of a drug known as "Bayer 205" in Rhodesia and the Congo in cases of human sleeping sickness and trypanosomiasis of domestic animals—diseases which are such a serious handicap to the development of Africa. It is well known that salts of arsenic and antimony are able in many cases to control these diseases, but these remedies are far from satisfactory, and the remarkable results which were reported in Germany in 1922 in the treatment of experimental trypanosomiasis in animals and in dourine of horses with the new drug "Bayer 205," the composition of which has not yet been made public, aroused much enthusiasm. The completely satisfactory treatment of a human case in Hamburg, after arsenic and antimony had failed at the Liverpool School of Tropical Medicine, excited considerable interest. Other patients were treated at the London School of Tropical Medicine, and it became evident that in many cases the drug had a rapid action on the trypanosomes, and, so far as can be said at present, has effected a permanent cure. The one disadvantage is a certain irritative action on the kidneys, which, however, is not of a permanent nature. Prof. Kleine was granted permission by the British Government to conduct experiments in Rhodesia, and the published accounts of his work show that the hopes which were entertained were fully justified, and that cures can be effected in a large percentage of natives suffering from sleeping sickness even in its advanced stage. As regards the trypanosomiasis of domestic animals, he has noted that it is only efficacious in ridding them of trypanosomes which are most closely related to those which produce disease in man. Experiments on the prophylactic action have shown that if cattle which are to be exposed to the bites of tsetse flies are given an injection of the drug before exposure, the chances of infection are reduced, and even if infection does occur its course is considerably modified. It is understood that Prof. Kleine will, in the near future, give an account in London of his experiences.

IN some cases the American graduate appears to receive a farewell address of the nature of a "pastoral charge" before he leaves the university to make his own way in the world. Such an occasion obviously encourages platitudes, but we may be grateful that the issue of *Science* for October 19 enables Prof. Millikan's address to a graduate class at Stanford University, California, to reach a wider public. He recalls that Senator John Sherman, when addressing a class of graduates in 1891 in which Millikan was included, told them their problem was to make democratic government work in a country three thousand miles one way, by two thousand the other, a government and a country which had been preserved to them by the sacrifices made to them by his generation. Now, as the result of untold sacrifice, 1923 finds the world, by no means yet ready for the task, presented with the problem of making democracy work on a huge scale, not only in the United States of America but also in almost every important nation on earth. Prof. Millikan finds that one of the greatest contributions that science makes to the problem is the discovery that progress is in general made by the evolutionary process. "The whole of Newton is incorporated in Einstein." He decides that if bullets are to be replaced by ballots it will only be "because the nations of the earth learn to take a more rational, a more objective, a more scientific attitude towards life and all its problems." . . . "For in the jungle ignorance and prejudice and impulse and emotion must determine conduct, and so long as that is the case none other save the law of the jungle is possible." Prof. Millikan has no nostrum to propose to eliminate the jungle influence, but looks to "the slow growth of a larger degree of both public intelligence and public conscience than we now have. Intelligence enables one to know better what he ought to do, while conscience keeps him doing as he knows he ought." He concludes that "science, imbued with the spirit of service, which is the essence of religion, and religion guided by the intelligence, the intellectual honesty, the objectiveness and the effectiveness which is char-

acteristic of the spirit of science, can between them, without a shadow of doubt in view of the rate at which discoveries are now being made and at which changes are being brought about, transform this world in a generation."

At a recent meeting of the Zoological Society, Mr. R. T. Gunther exhibited some vertebræ of a marine Jurassic crocodile, Steneosaurus, which were marked on the sides with discoloured grooves apparently due to contact with blood-vessels. In a letter to the *Times* of December 7, he reported that a dissection of the intercostal arteries of a modern crocodile by Mr. R. H. Burne had confirmed this idea, and he suggested that the unusual markings may have been produced by some calcification of the arteries due to a gouty condition, perhaps in old age. As the appearances are almost unique, Mr. Gunther has presented one of the vertebræ to the Geological Department of the British Museum, where it is now exhibited. The discovery led Prof. Elliot Smith, in a letter to the *Times* of December 12, to recall observations of blood-stains on human bones from Egypt and Nubia, from 4000 to 5000 years old, made by Prof. Wood Jones and himself. In a subsequent letter to the *Times*, Mr. Reid Moir advises caution in interpreting red or brown stains on fossil bones as marks of blood, most of these being evidently due to the deposit of oxides of iron by percolating water.

The Library of the Chemical Society will be closed for the Christmas holidays from Monday, December 24, until Thursday, December 27, inclusive.

Sir Charles Sherrington has received an official communication from the Institut de France informing him that he has been elected a corresponding member of the Section of Medicine and Surgery of the Paris Academy of Sciences, in succession to the late Sir Patrick Manson.

The Christmas Juvenile Lectures at the Royal Institution, "Concerning the Nature of Things," to be delivered by Sir William Bragg, commence on Thursday, Dec. 27, at 3 o'clock. Succeeding lectures are on Saturday, Dec. 29, Tuesday, Jan. 1, Thursday, Jan. 3, Saturday, Jan. 5, and Tuesday, Jan. 8.

The Board of Trade announces that by virtue of the Importation of Plumage (No. 2) Order, 1923, the green (or Japanese) pheasant (*Phasianus versicolor*), order Galliformes, and the copper pheasant (*Phasianus Soemmerringi*), order Galliformes, have been removed from the schedule to the Importation of Plumage (Prohibition) Act, 1921. The importation of the plumage of the above-mentioned birds will, therefore, not be permitted without licence on and after January 1, 1924.

The *Illustrated London News* of December 15 publishes an account by Mr. R. C. Andrews of the discovery of eggs of deinosaurs in the Cretaceous rocks of Mongolia, with excellent photographs of some of the specimens. To emphasise the fact that at least one egg attributed to a deinosaur has been known for many years, it also publishes a photograph of fragments of this egg which have long been in the British Museum. The earlier specimen was found with part of the skeleton of Hypselosaurus in an Upper Cretaceous formation in Provence, France, and the outer surface of the shell is tuberculated like that of the new eggs.

The following committee has been appointed by the Royal Academy to investigate the quality of artists' materials and the various methods of cleaning old pictures: Sir Aston Webb, Mr. S. J. Solomon, Mr. G. Clausen, Mr. C. Shannon, Prof. A. P. Laurie, Sir Herbert Jackson, Sir Arthur Schuster, Dr. A. Scott, Mr. C. F. Cross, Dr. W. W. Taylor, Dr. R. S. Morrell, Mr. N. Heaton, Mr. P. Tudor-Hart, Mr. J. D. Batten, and Mr. F. E. Jackson.

In the notice of a "scientific novel" in Nature of September 1, p. 320, Mr. H. G. Wells was mentioned as the first to exploit in imaginative literature the idea of liberating the energy of the atom. Prof. W. A. Osborne, of the University of Melbourne, thinks this is incorrect, and remarks in a letter to us, "I should not be surprised if the first use in fiction of the possibility of unlocking atomic energy occurred in 'The Crack of Doom,' by the late Mr. Robert Cromie. This story was published in 1895 by Digby Long, and shortly afterwards a cheap reprint appeared from the house of Newnes."

A series of articles on the reconstruction of Tokyo has recently appeared in the *Times* (December 12, 13, and 15). The total value of the houses destroyed in the city is estimated at about 146 million pounds, the number of houses lost being 224,567, of which more than 97 per cent. were burnt. According to Prof. Ichikawa, fire broke out after the earthquake in the building adjoining the University Library. The water supply had already ceased, and, although every effort was made to screen the various rooms, the fire swiftly penetrated into them, the destruction of the library and the greater part of its contents being the work of a few moments.

The Prince of Wales has consented to become the first member and president of the Fellowship of the British Empire Exhibition, a non-party organisation which has been formed to promote Empire unity. The subscription for membership, two guineas, entitles the member to a certificate of membership, a badge, and a season ticket to the Exhibition at Wembley. The funds thus raised are to be devoted to scholarships for university or technical education, each of the value of 1000*l*. No details are given of the conditions of awards except that candidates must be citizens of the British Empire and either members of the Fellowship or nominated by members. In accepting the presidency of the Fellowship, the Prince expresses the hope that its programme of Imperial education and settlement scholarships will play a valuable part in promoting knowledge of the Empire.

In addition to the letter from Dr. H. H. Mills, printed in last week's Nature, page 865, we have received several others in which different views are expressed upon Mrs. Hertha Ayrton's scientific work and influence from those given by Prof. Henry E. Armstrong in the obituary notice which appeared

in our issue of December 1. One of the subjects especially referred to is the anti-gas fan, of which it is pointed out that more than 100,000 were used during the War. As, however, a full discussion of this device as a protection from gas attacks appeared in 1920 in vol. 105 of NATURE, pp. 336, 422, 453, and 612, and Mrs. Ayrton herself took a leading part in it, no useful end would be served by going over the same ground again. With regard to her work on the electric arc, it may be remarked that an appreciation of it appeared in the Journal of the Institution of Electrical Engineers for October last, over the initials of a distinguished authority on electrical engineering.

IN view of the high standard of the essays sent in for the R. 38 Memorial Prize, 1923, the Council of the Royal Aeronautical Society has decided to increase the amount for this year only from 25 guineas to 40 guineas, and to divide the prize between the papers on "The Aerodynamical Characteristics of the Airship as deduced from Experiments on Models, with Application to Motion in a Horizontal Plane," by Mr. R. Jones, and "A Detailed Consideration of the Effect of Meteorological Conditions on Airships," by Lt.-Col. V. C. Richmond and Major G. H. Scott. Both these papers will be published in the Journal of the Royal Aeronautical Society, together with the paper on "The Strength of Rigid Airships," by Mr. C. P. Burgess, Commander J. C. Hunsaker, and Mr. Starr Truscott, which the Council mentions as deserving special commendation. Intending competitors are reminded that the names of entrants for the 1924 prize should be sent in to the Secretary, Royal Aeronautical Society, 7 Albemarle Street, London, W.1, on or before Dec. 31; the last date for the receipt of the papers is March 31, 1924.

THE annual exhibition of the Physical Society of London and the Optical Society, which is to be held on Wednesday and Thursday, January 2-3, at the Imperial College of Science and Technology, South Kensington, will be open in the afternoon (3-6 P.M.) and in the evening (7-10 P.M.). Mr. H. B. Grylls will give a lecture on "The Heape and Grylls Rapid Cinema Machine" at 4 P.M. on January 2 and at 8 P.M. on January 3. Sir Richard Paget will give a lecture on "The Nature and Artificial Production of Human Speech (Vowel Sounds)" at 8 P.M. on January 2 and at 4 P.M. on January 3. More than fifty firms are exhibiting scientific apparatus, and a number of experimental demonstrations have been arranged. Invitations have been extended to the Institutions of Electrical and Mechanical Engineers, the Chemical Society, the Radio Society of London, the Röntgen Society, and the Faraday Society. Admission in all cases will be by ticket only, and members of the above Societies should apply to their secretaries. Others interested should apply direct to Prof. A. O. Rankine, hon. secretary of the Physical Society, Imperial College of Science and Technology, South Kensington, S.W.7.

SCIENTIFIC work in Egypt has just lost a strong supporter owing to the retirement of Mr. E. M. Dowson from the post of Financial Adviser to the Egyptian Government. This post is the highest in the Egyptian Government Service open to a non-Egyptian. Mr. Dowson joined the Service in 1901 as a member of the Survey Department, and on the retirement of Colonel Lyons in 1909, was made Director-General. During the latter part of the War he acted as Under Secretary of State for Finance and later as Financial Adviser, to which post he was definitely appointed in 1919. Having been head of a scientific department he knew the importance of scientific research to the progress of a country and fostered it in every way he could. Of the work carried out under his direction one may mention the geodetic triangulation of Egypt and the precise levelling of the Nile valley. He was also responsible for a number of improvements in the organisation of scientific work under the Egyptian Government, including the formation of the Cotton Research Board and the transfer of the Physical Service to the Ministry of Public Works as a separate department.

A USEFUL piece of work has been done by the British Industrial "Safety First" Association in issuing a revised and extended version of the illustrated pamphlet by Mr. Leon Gaster on "Good Lighting as an aid to Safety." The underlying principles of good lighting are based on a great deal of patient scientific work and somewhat complex investigations, but the main conclusions are here set out in quite simple terms and are illustrated by many telling sketches and photographs. There are, for example, pictures showing how various forms of accidents may be caused by bad lighting, and charts indicating how the frequency of industrial accidents is greatest during the dark winter months. Examples of improved output following the adoption of scientific methods of lighting are quoted, and it is pointed out that the cost of adequate illumination is usually less than 1 per cent. of the cost of production. Reference is also made to lighting conditions in mines and on the railways. The chief recommendations of the Home Office Departmental Committee on Lighting in Factories and Workshops are explained, and the classification of operations into two classes, "fine work" (requiring not less than 2-ft.-candles, and "very fine work" (requiring not less than 5-ft.-candles), is incorporated in the booklet as an appendix.

IN consequence of the existence of the Colorado beetle in France, and in order to prevent the introduction of this dangerous pest into England and Wales, the Ministry of Agriculture and Fisheries deemed it necessary in the early part of 1923 to issue an Order (the Colorado Beetle Order of 1922) which in effect prohibited the entry into Great Britain of living plants and vegetables grown in a wide area in France. Following representations made to the Ministry, and as a result of the visit of investigation to the infected region in France which was made by the Ministry's entomologist during the autumn, it has now been decided to amend the regulations. The Colorado Beetle Order of 1923 has accordingly been issued and came into operation on December 17, revoking the corresponding Order of 1922. The effect

of this new Order will be that in place of the declaration required at present, each consignment of living plants, potatoes, or tomatoes shipped from ports in European France to Great Britain must in future be accompanied by a particular certificate or copy certificate, which must be delivered to an Officer of Customs at the same time and together with the entry relating to the consignment. In future no certificate or declaration of any kind will be required in the case of vegetables for consumption other than potatoes or tomatoes.

A SERIES of articles on "Science and Industry in America," from the pen of Dr. W. Rosenhain, has recently appeared in the *Engineer*, and in the concluding article, on October 26, the author sums up his impressions derived from visits to a large number of scientific and industrial laboratories in North America. It is remarkable that the enormous development of certain laboratories devoted to industrial research, whether under the management of a commercial body, such as the General Electric Co., or of a Government department, such as the U.S. Bureau of Standards, has noticeably had a paralysing effect on the universities, some teachers of science imagining that it is useless for them, with limited equipment, to enter into competition with such great institutions. Such an impression, as the author remarks, would be most unfortunate if it were to become general. The employment of so many competent physicists and chemists in industry has to some extent injured the scientific staffs of the universities, and the standing of the men in charge of teaching and research is not always as high as might be expected from the wealth and population of the country, and from the vast sums expended on buildings and equipment. On drawing up a list of the most eminent men in various branches of scientific investigation, the proportion of Americans is disappointingly small, when the resources of the country are taken into account. This attitude of America towards science and its applications is recognised and deplored by American men of science themselves, and it is a subject of speculation how long it will take so great a nation to awake to the necessity of a change in this respect.

BULLETIN No. 717 of the Department of the Interior, Washington, is on "Sodium Sulphate: its Sources and Uses," by R. C. Wells. This pamphlet deals with the mineral forms of sodium sulphate together with salt cake, nitre cake, and Glauber's salt. The sulphate process of making wood pulp is also described. The booklet is well illustrated with diagrams of crystal forms, equilibrium diagrams, etc.

WE have received from the Canadian Department of Mines a copy of a report on titanium by A. Robinson. The three parts into which the book is divided deal with the metal and its compounds, its occurrences in Canada, and the production and uses of the metal respectively. The book is well illustrated with maps and diagrams. The uses to which titanium and its compounds may be put are fully discussed. These include its use in the metallurgy of steel, arc light electrodes, pigments, mordants, and in the ceramic industry.

Our Astronomical Column.

MERCURY AN EVENING STAR.—Mercury will be visible to the naked eye on a few evenings at the end of December, the planet being above the horizon more than $1\frac{1}{2}$ hours after sunset. At about 5 P.M., Mercury will be visible on very clear evenings a little above the W.S.W. horizon, shining with a rosy light and scintillating after the manner of a fixed star. The brilliant planet Venus will be situated about 8° to the eastwards and afford a clue to the exact position of Mercury, which will shine with far less lustre. A field-glass might be employed to advantage. Early in January, Mercury will disappear from the evening sky, but Venus will remain very conspicuous in the twilight during the ensuing winter and spring months.

THE EINSTEIN SHIFT IN THE SOLAR SPECTRAL LINES. —Allusion was made in this column recently to the announcement of Prof. C. E. St. John that he was satisfied that this shift really exists. He gave further details in a paper read at the meeting of the Royal Astronomical Society on December 14; in his previous researches he had felt it necessary to confine himself to lines that are not subject to pressure shift. But now that the pressure in the photosphere is proved to be low, the choice of suitable lines for measurement is greatly widened. In studying the wave-lengths of iron lines at the centre of the sun's disc and at different levels in the photosphere, he finds a shift in excess of Einstein at the highest levels, in agreement with Einstein at the middle levels, and in defect at the lowest ones; these could be explained by downward and upward currents in the respective regions, superposed on the general Einstein displacement. He also found the latter displacement at the sun's limb; here, too, some other influence was superposed on it; scattering due to the greater thickness of solar atmosphere traversed by the rays was suggested. Mr. Evershed expressed himself in full agreement with the conclusions, but Prof. Newall thought the evidence was still not decisive, as many other disturbing influences were at work on the sun, *e.g.* the Stark effect, polarisation and anomalous dispersion; the observed displacement might be due to these.

FIXED CALCIUM CLOUDS IN INTERSTELLAR SPACE.—Mr. J. S. Plaskett has made an examination of the radial motion indicated by the calcium lines in some Cepheid stars of early type which have been found not to partake of the periodic shift of the other spectral lines. It has for some time been considered that these stars are surrounded by calcium clouds. It is now found that these clouds in various regions of the heavens appear to be stationary relatively to the general system of the stars. The clouds would thus seem to be independent of the particular stars showing the lines, and it was suggested at the meeting of the Royal Astronomical Society on December 14 that there might be a general diffusion of calcium vapour throughout the stellar system, but that in most stellar spectra its presence is masked by the strong H and K lines belonging to the stars themselves. Various difficulties were referred to in the discussion. Some thought that the clouds would be luminous and show bright lines; another difficulty is the practically perfect transparency of the stellar spaces which Dr. Harlow Shapley deduced from his work on the globular clusters. The subject is still somewhat obscure.

Research Items.

EARLY HITTITE RECORDS.—Valuable additions to our knowledge of the early history and political relations of the peoples of Western Asia are made by Prof. Sayce in the concluding part of *Ancient Egypt* for the current year, which has just appeared. Prof. Sayce translates some of the early cuneiform Hittite tablets, recently published by Dr. Forrer, which relate the campaigns of Sargon of Akkad and Naram Sin in Asia Minor. Naram Sin's enumeration of seventeen kings who formed an alliance against him includes rulers of cities in Babylonia, Northern Syria, and Eastern Asia Minor, and proves the intimate connexion which existed between all parts of Western Asia in the third millennium B.C. From one of the Boghaz-Keni tablets, in a record of a later King Telibinus, we now learn that the leader of the Hittite invasion of Babylonia, about 1900 B.C., which overthrew the Amorite dynasty of Khammurabi, was Mursilis I. Telibinus also gives a list of the cities over which he ruled, including Damascus. This is the earliest mention of this city in cuneiform tablets. It indicates that the Hittite sovereignty extended southward as far as the northern boundary of Palestine, and explains how Hittite settlers found their way to Hebron in the time of Abraham.

MATHEMATICAL WORK OF JAMES GREGORY.—In vol. xli. of the Proceedings of the Edinburgh Mathematical Society, Prof. G. A. Gibson gives a critical and historical account of the work of James Gregory. To the ordinary student of mathematics, Gregory is now known almost solely as the man who first used the phrase "converging series" as a technical term, and as the author of the series for $\tan^{-1}x$. The latter series is comparatively unimportant, not a fundamental series like Taylor's, and it is very unlikely that it would have been associated with Gregory's name but for the part it played in the Newton-Leibniz controversy. Yet all contemporary references to Gregory show that he was considered to be among the first mathematicians of his day, quite apart from his fame as the author of the "Optica Promota." Undoubtedly the books he published were of sterling merit, though comparatively few references to them exist in modern mathematical literature.

AL-RAZI [RHAZES] AS A PIONEER CHEMIST.—In No. 3-6 of vol. xliv. of the *Deutsche Literaturzeitung* (Berlin, 1923), Prof. Julius Ruska, of Heidelberg, has an article on the contributions to chemistry of the Persian physician Al-Razi (died A.D. 923 or 932). He points out that a satisfactory history of Islamic medicine and chemistry is still lacking, and remarks that it is necessary to get back to the texts themselves. According to Prof. Ruska, Al-Razi's chemistry, as found in his "Book of the Secret of Secrets," is characterised by the inclusion of a good deal of new material unknown to the Greek alchemists, and also by the classification of chemicals into three classes, according to their origin from animals, plants, or minerals. Prof. Ruska attributes to Al-Razi in addition (*a*) the introduction of sal-ammoniac, and (*b*) the first systematic and well-organised treatment of particular chemical reactions; here, however, he is inaccurate, since Jabir ibn Hayyan (died about A.D. 813) mentions sal-ammoniac very frequently, noting both the natural product and that made from hair, and also devotes several small books to a consideration of such operations as calcination, distillation, sublimation, etc. As Al-Razi was certainly well acquainted with Jabir's books, it is clear that a great deal of the credit for the pioneer work to which Prof. Ruska refers must be given to the latter chemist. It is interesting to note how modern research is restoring to the Muslims the great reputation for chemical skill which they possessed for so long, though it suffered heavily in the latter half of the nineteenth century.

PHYTO-PATHOLOGY IN HORTICULTURE.—The *Gardener's Chronicle* for November 3 contains, under the general title "The Relation between Horticulture and Phyto-Pathology," the first instalment of a paper by Prof. Johanna Westerdijk, read at the International Horticultural Congress at Amsterdam in September last. Dealing with problems of unusual difficulty, this paper seems to be singularly clear and precise, and is none the less valuable for its frank recognition of the numerous lacunæ in our scientific knowledge of the life-history and method of spread of many important horticultural diseases. The present instalment contains a wealth of data upon two important problems—(1) the need for sterilisation of seeds in the case of certain diseases and the methods adopted in various countries in such processes of sterilisation; (2) the successful growth of plants in "sick" soils by the genetic selection of resistant strains.

TREES OF THE GOLD COAST.—The Bulletin of the Imperial Institute, volume 21, No. 2, 1923, contains an interesting account of the trees of the Gold Coast, which is based upon information supplied by Dr. J. M. Dalziel, senior Sanitary Officer of the Gold Coast, and illustrated by four excellent photographs. The trees described occur mainly in the deciduous forests of what is sometimes called the Sudan zone of vegetation. From the forestry point of view the trees are not of great value, but they have many local uses for timber, fibre, gums, and fuel, etc., while the fat of the shea-butter tree (*Butryospermum Parkii*) gives to the open park-savannah forests considerable economic value.

OCEANOGRAPHY OF THE JAVA SEA.—A gap in the oceanographical knowledge of the waters of the Malay archipelago has been filled by the researches of Mr. K. M. van Weel in the Java and South China seas from 1917 to 1920 (Meteorological and hydrographical observations in the western part of the Netherlands East Indian Archipelago: *Treubia*, vol. iv. pt. 1-4, 1923). The lengthy memoir is accompanied by a portfolio of 28 distributional charts. The floor of the Java Sea is shown to slope gently downwards from Sumatra towards the east, barely reaching a depth of 100 metres to the west of Macassar Strait. East of the 100 metre isobath the depths appear to increase suddenly, but this is outside the area of Mr. van Weel's survey. A remarkable feature is a deep channel in Sunda Strait between Sumatra and Java. An erosion channel caused by a strong current moving out of the Java Sea suggests itself, but this explanation does not fit the facts. Mr. van Weel is disinclined to regard it as a tectonic chasm as has been suggested, and leans to the belief that it represents the sunken valley of a large river. He accepts Molengraaff's pleistocene continent on the site of the Java and China seas, and regards the Sunda submarine channel as a submerged feature of that land. All hydrographical as well as a number of meteorological observations are given in full.

RIVER POLLUTION.—The pollution of the River Tyne, and its deleterious effect on the salmon fisheries

is the subject of a well-written paper by Miss E. M. Meek in the report of the Dove Marine Laboratory for 1922–23. Fifty years ago the salmon fisheries of the Tyne were more than ten times as prosperous as they are to-day, and almost conclusive evidence is now given to show that the decline of this industry is due to sewage pollution. The paper is of general interest since it is illustrated by a series of curves correlating the effect of sewage contamination upon the oxygen content of the water. The result of an experiment on *Zoarces viviparus* indicates that the toxicity of the sewage is directly due to foreign substances in the sewage and not to the reduced oxygen content of the water. It would be interesting to know to what extent sewage must be diluted in order that this fish can continue to breed under experimental conditions; also, what is the direct effect, if any, of the reduced oxygen supply.

BOUNDARIES IN THE UNITED STATES.—Bulletin No. 689 of the United States Geological Survey is a complete account of the boundaries, areas, geographic centres and altitudes of all States in the United States, including oversea possessions. It is a revised and enlarged edition of a bulletin that was first published in 1885 and has been republished with additions several times since that date. A brief introduction discusses how boundaries are established and changed, but the greater part of the volume deals with the boundaries of the different States. Full details of the present position of the boundaries and of all past changes are given, with detailed references to treaties and other State documents. In addition to a number of sketch maps, there is a large reproduction of the second edition of the Mitchell map of the British and French dominions in North America as printed in 1774 or 1775. This was the map that was used in forming the peace treaties of 1782 and 1783, for in spite of its imperfections it was the best available at the time. A coloured map shows the routes of the principal explorers from 1501 to 1844 in the territory now covered by United States jurisdiction. The publication contains a great deal of valuable material for the study of the evolution of boundary lines and frontiers.

PHILIPPINE EARTHQUAKES.—The Philippine archipelago is one of the most active seismic regions in the world; yet, near its centre, lies the long narrow island of Cebu, in which, for the last four centuries, almost the only earthquakes felt have come from outside. On this account, the earthquakes that may be considered as belonging to it are of interest, if only in showing that historic time may be too brief to reveal all the areas of seismic change. One earthquake that caused slight damage in Cebu occurred in 1887, and a second on February 28, 1922. The latter is the subject of a brief report by the Rev. M. Saderra Masò, the historian of Philippine earthquakes (Bulletin of the Weather Bureau, Manila, for February 1922). The area of damage included the capital city Cebu and the small island of Mactan to the east. In the channel between the islands, beneath which the origin probably lay, unusual movements of the sea were observed, and on the same day, but at an unknown hour, the cable crossing it was broken.

SUB-SURFACE GEOLOGY IN OILFIELDS.—Until the last few years, sub-surface structural analysis in oilfield work tended to be a very haphazard process. Too often subterranean structures have been described in terms of mapped surface evidence, and methods of correlation of well-log data have been in the main of a somewhat crude character, until the technique of palæontology and petrology was acquired in dealing with the evidence adduced from drilling operations. Some recent reports of petroleum geologists attached to the United States Geological Survey have shown that the necessity for more detailed work of this character is now fully appreciated, and a great deal of minute investigation is being prosecuted in this connexion. It is therefore somewhat of a surprise to see that in the case of the sub-surface study of the Pershing oil and gas field, Osage County, Oklahoma, the author, Mr. W. W. Rubey, has adopted methods depending almost entirely on drillers' reports, graphic well-logs, field-statistics, and the like, rather than the more highly technical and certainly more convincing methods of study. It is open to doubt as to how far graphical methods of interpreting oil-well behaviour lead to really important evidence which may be used as a basis of deduction of subterranean conditions and as a guide to the future course of developments of the oilfield concerned. As criteria of geological circumstances, individual or even collective oil-well performances are of doubtful value if studied without reference to as comprehensive a knowledge of the unexposed rocks as possible. It is not to be expected of the average driller that he is trained in even the elements of lithology; his terminology is necessarily crude and in many instances untrustworthy. It is for the geologist to analyse and name the samples, just as it is his business to use those results for precise correlation below ground. Thereafter, by co-ordination of such evidence and all other statistical data furnished during the life-history of each well, he is in a position to supply the operators with all the information necessary to economical development of the field as a whole.

RAINFALL IN SUMATRA.—The Royal Magnetic and Meteorological Observatory at Batavia has recently published, in Verhandelingen No. 11, a summary of rainfall in the northern part of "Sumatra's Oostkust," by Dr. J. Boerema. The observations are made at the official rainfall stations and the figures are not used unless they cover a period of at least 5 years. There are 288 stations available and in addition 22 stations in Atjeh and 4 in Tapanoeli. Monthly and annual results have been calculated for a normal period of 20 years. Maps for the year and for each month show the areas of equal amounts of rainfall for practically the whole country; also the months of maximum and minimum rainfall. It is estimated by discussion that a monthly mean rainfall calculated from 5 years' observations may differ to the extent of 40 to 50 per cent. from the average obtained from a long series of observations, say 35 years; in the case of 10 years' observations, the deviations are reduced to about half that value. For 30 years the difference from the 35-year normal is only 3 per cent. The rainfall increases from the coast to the mountains, the annual map showing a general rainfall of about 60 to 100 inches near the north-east coast to about 150 to 260 inches in the mountains. An annual average of 263 inches is given at Bandar Baroe. The rainiest season is October and November, with a secondary maximum in April and May. The double tropical periods of rainfall are scarcely disturbed by the monsoons. The minimum rainfall occurs in February and June. Statistics are given of the monthly and annual amount and frequency of rainfall at all stations. More than ordinary interest is associated with the carefully worked results since Sumatra is divided by the equator and falls about equally in the Northern and Southern Hemispheres. Such discussions are of the highest value to the world's meteorology.

HEAT CONDUCTION IN LIQUIDS.—In the issue of the Proceedings of the American National Academy of Sciences for October 15, Prof. P. W. Bridgman, of Harvard, gives a summary of the results of his measurements of the heat conductivities of 15 liquids at 30° and 75° C., and at pressures up to about 12,000 atmospheres. The liquids were placed between two concentric metal cylinders, to the inner of which heat was communicated electrically and the difference of temperature of the two measured. For all the liquids tested, with the exception of water, the conductivity decreases as the temperature rises, and increases with rising pressure. For the more compressible liquids the conductivity at a pressure of 12,000 atmospheres is nearly three times that at atmospheric pressure. If the transfer of energy from molecule to molecule is assumed to take place with the speed v of sound in the liquid, the thermal conductivity should be $4v/d^2$, where d is the distance apart of the centres of consecutive molecules. This relation is shown to be satisfied approximately.

FIRING WITH PULVERISED COAL AND BLAST FURNACE GAS.—The firing of coal in a pulverised condition, that is, 90 per cent. through a 100 mesh screen (100 holes to the linear inch) and 65 per cent. through a 200 mesh, is attracting some attention in Great Britain. In the United States about 30,000,000 tons of coal per annum is being burnt in the pulverised condition, chiefly in the iron and steel, cement, and glass industries. Since 1920 the rapid growth in the application to steam generation has been remarkable, and very soon about 3,000,000 tons per annum will be absorbed in this one operation, although little or no progress has so far been made in Great Britain. One advantage of pulverised coal is that it will work in conjunction with blast furnace gas. In the operations of the blast furnace a large volume of low-grade gas is given off, averaging 90-110 B.Th.U. per cubic foot, with a composition of about $24\frac{3}{4}$ per cent. carbon monoxide, $5\frac{3}{4}$ per cent. carbon dioxide, $2\frac{1}{4}$ per cent. hydrogen, $\frac{3}{4}$ per cent. methane, and $66\frac{1}{2}$ per cent. nitrogen. As a rule the surplus gas is burnt on very crude lines under steam boilers, and because of the great fluctuations in the supply, generally coal has to be used as an auxiliary fuel. This gives bad results, since it is difficult to keep pace with the variations in the gas supply. For these conditions, however, pulverised fuel is good, since it is almost as easy as gas to regulate and adjust, and can be started up or shut down in a few minutes. A good example of this principle is the huge River Rouge power plant of the Ford Motor Co. at Dearborn, Detroit, where 70 per cent. blast furnace gas and 30 per cent. pulverised coal is burnt without difficulty. It has been stated that by neglecting this means of utilising blast furnace gas, Great Britain is at present wasting more than 1,000,000 h.p.

THE EARTH'S ELECTROSTATIC FIELD.—In the September issue of *Terrestrial Magnetism and Atmospheric Electricity*, Dr. S. J. Mauchly reviews the evidence now available as to the daily variation of the potential gradient in the air over both land and sea. The land observations were made at nearly 20 stations between Cape Thordsen in latitude 78° north and Cape Evans in latitude 77° south, and the ocean observations on board the magnetic observing ship *Carnegie* in the Pacific, Atlantic, and Indian oceans. Dr. Mauchly finds that as a first approximation the gradient varies daily from 80 or 90 volts per metre at 4 o'clock to 110 or 120 volts per metre at 18 o'clock Greenwich mean time at all land and sea stations. There appears to be some variation of the magnitude of the daily change and of the time at which the maximum gradient is attained, with the season of the year and with the locality, but these are not sufficient to invalidate the general conclusion. In mid-Pacific and at land stations during June and July, a reduction of the amplitude of the daily change makes it evident that there is also a 12-hour wave, but the observations are not yet numerous enough to justify conclusions being drawn as to its nature and its generality.

SYNTHESIS OF BENZENE.—The classical experiment of Berthelot on the polymerisation of acetylene to benzene, made so far back as 1858, was a fundamental synthesis of benzene, and is still quoted in the textbooks. The yield of benzene and allied hydrocarbons, however, was so small that much experimental skill was necessary to prove their presence. The results were not greatly improved by the use of catalysts, the main action in all cases being the decomposition of the acetylene into its elements. In the *Comptes rendus* of November 5 of the Paris Academy of Sciences, N. D. Zelinsky describes experiments on the polymerisation of acetylene in the presence of activated wood charcoal at 640° to 650° C. Under the conditions described, more than 70 per cent. of the weight of the acetylene passed over the charcoal was converted into liquid products. From this liquid absolutely pure synthetic benzene (303 gm.) was obtained, and other substances isolated from the condensate included toluene, *p*-xylene, styrol, indene, naphthaline, fluorene, and anthracene.

SCOTT-STILL MARINE ENGINES.—A great deal of experimental work on the Still engine has now been done by Messrs. Scotts' Shipbuilding and Engineering Company of Greenock, and their experience has enabled the firm to consider the application to actual vessels. The m.s. *Dolius* is now fast approaching completion, and is the first in which a large-scale installation of Scott-Still engines has been fitted. In this system the cylinder on one side of the piston is used as an oil engine (two-stroke Diesel cycle) and on the other side as a steam engine. The water in the jackets is kept at working steam pressure, and any heat passing through the cylinder walls is used to generate steam. Heat is also recovered from the exhaust gases by means of a regenerator, and also by a feed heater. The m.s. *Dolius* is 400 ft. long and has a displacement of 11,650 tons. The total power of 2500 b.h.p. is divided between two main engines of four cylinders, each 22 in. diameter and 36 in. stroke, and running at 115 to 120 revs. per min., giving a ship speed of about 11 knots when fully loaded under service conditions. Steam is generated at about 140 lb. per sq. in., and is first employed at the back of the piston in one cylinder acting as a high-pressure piston, and then is taken to the other three cylinders, which together act as the low-pressure cylinder. Official trials of the engines have been made by the Marine Oil Engine Trials Committee appointed by the Institutions of Mechanical Engineers and Naval Architects. Their report has not yet been issued, but the following summary is available: Average mean effective pressure, oil engine, 77·8 lb. per sq. in.; average m.e.p. steam cycle referred to oil engine volume, 6·6 lb. per sq. in.; total average m.e.p., 84·4 lb. per sq. in.; revs. per min., 122; total indicated horse-power, 1425; brake horse-power, 1251; mechanical efficiency, 87·8 per cent.; oil consumption per b.h.p. per hour, 0·356 lb.; steam evaporated per hour, 2400 lb. An account of the engine, with photographs and drawings, appears in *Engineering* for November 23.

The British Empire Exhibition, 1924.

WIDESPREAD interest throughout the British Empire and elsewhere was aroused by the Imperial Conference, attended by statesmen and representatives from the constituent parts of the Empire, which recently concluded its sittings in London. Among the subjects dealt with at this historic gathering was the natural resources of the Empire and their exploitation, and practical expression to many of the points raised will be given by the British Empire Exhibition to be held next year at Wembley. During the summer months, from April until October, the Exhibition will be a centre of attraction throughout the British Empire and indeed throughout the world. The immediate object will be to furnish a display of the natural resources of the countries of the British Empire and the activities, industrial and social, of their peoples; the ulterior motive is the promotion of Imperial trade. In effect, it should be an impressive spectacle demonstrating the progress of civilisation.

The scheme for a British Empire Exhibition was put forward in 1913 by the late Lord Strathcona, but it was not until 1919 that definite steps were taken to promote such an exhibition. A provisional committee secured the approval of the Board of Trade, the King graciously consented to become patron, and in June 1920 the project was formally launched at a meeting held at the Mansion House. The Prince of Wales became president of the general committee, and in December 1920 an Act of Parliament was passed authorising the Government to contribute to the guarantee fund, and the Dominions Overseas were formally invited to take part in the Exhibition. A site of 150 acres, since increased to 200 acres, was selected at Wembley, and work was commenced.

The magnitude of the part in the Exhibition which will be taken by the Dominions Overseas can be gathered from the following figures: at the Paris Exhibition of 1900, they had 60,000 sq. ft.; at the White City in London in 1908, 110,000 sq. ft.; at Wembley they are having 600,000-700,000 sq. ft. of space. Most of the Dominions are building pavilions to display their exhibits. Australia is spending a quarter of a million pounds on its display; the Indian Empire, about 167,000*l.*; New Zealand, a minimum of 60,000*l.*; and the other Dominions, amounts in accordance with their size. The building for Australia alone covers 150,000 sq. ft., while the Government of India has occupied 100,000 sq. ft.

Other noteworthy buildings within the grounds are the Palaces of Industry and Machinery, and the agriculture section, which will house the Home Country exhibits, and a building for the conferences which are to be an important feature of the Exhibition. To turn to a lighter side, there is a sports stadium about one and a half times the size of the Coliseum at Rome, which will accommodate 125,000 spectators, and an amusement park where the usual exhibition amenities will be provided. All the principal buildings of the Exhibition are of a permanent and substantial nature, and it is hoped that the site will be the home of future large-scale exhibitions.

The British Empire Exhibition is itself of the nature of a company, and the funds necessary for the organising work and construction have been advanced by banks on the security of the guarantee fund. It is hoped that the receipts from gate-money, sale of space in the Exhibition, and other sources of revenue, will render it unnecessary to call on the guarantors. At the close of the Exhibition, the property will be vested in a body of trustees to administer as a site for exhibitions, and any profits obtained, subject to a first charge in favour of the guarantors should it have been necessary to call upon them, is to be devoted to public objects.

In order that the Exhibition may fulfil its purpose—to display the natural resources of the British Empire and the activities of its people—it is obvious that a wide range of exhibits must be included. To all, the general condition is attached that, if manufactured, they must have been manufactured mainly within the Empire, or, if raw materials, they must have been produced within the Empire. To organise such a vast and varied collection is a task of no mean order. For this purpose the exhibits have been divided into 10 sections, 45 groups, and 150 classes. Among the section headings are food, which includes agriculture, fisheries and food-products; raw materials, including minerals and forest products; education, science and art, including the several grades of education and human, animal, and plant diseases of the tropics. Groups in other sections are devoted to aeronautics, telegraphy and telephony, chemical plant, dyes, instruments, hygiene and sanitation, and social economy. More than thirty committees have been appointed, each consisting of experts in a particular subject or branch of industry, to deal with the exhibits. In some cases, the organisation of exhibits has been undertaken by recognised trade associations; *e.g.* the British Engineers' Association is arranging the general engineering section, the British Electrical and Allied Manufacturers' Association the electrical engineering section, the Society of Motor Manufacturers and Traders the motor transport section, and the Association of British Chemical Manufacturers the chemical section. Pure science exhibits are being arranged by the Royal Society and the Association of British Chemical Manufacturers, the latter body having undertaken the whole of the pure chemistry side.

The chemical section itself will be a self-contained hall with about 40,000 sq. ft. of floor space within the Palace of Industry, and the chemical manufacturers' association is spending 100,000*l.* on it. The bulk of the space will be devoted to exhibits from the leading firms of chemical manufacturers in Great Britain, which will be arranged roughly in five groups: (1) heavy chemicals, (2) dyestuffs and intermediates, (3) fine chemicals, (4) soap and perfumery, and (5) scientific. One small section within the Chemical Hall, 2500 sq. ft. in area, will be devoted to pure chemistry, and it is hoped to demonstrate here the body of scientific research on which the chemical industry of Great Britain rests. The organisation of the scientific section is in the hands of a committee of representatives of scientific societies interested which was recorded in our issue of November 3, p. 665. This committee and the Royal Society's committee on scientific exhibits have three members in common, and in this way it is hoped to avoid overlapping.

It will not be possible in the space available for the scientific section to attempt a complete, standing exhibit illustrating the achievements of modern chemistry. The difficulty is to be overcome by providing a succession of exhibits which will follow one another during the period while the Exhibition remains open. For this purpose, the subject has been broken up into a number of sections or branches, and distinguished authorities in the various branches are arranging appropriate displays which will be "staged" in succession. A list of the names of those who have agreed to act in this capacity was given in NATURE of November 10, p. 700. In connexion with the work of the scientific section, a number of descriptive pamphlets indicating the nature

and purpose of the various exhibits will be available, and it is hoped to be able to publish a volume, each chapter of which will be contributed by an authority on the subject discussed, recording in more technical language the state of chemical knowledge at the time of the Exhibition. This volume should be a veritable milestone in the history of chemistry, and should prove a source of information and inspiration for scientific workers for years to come.

The onus of the success or failure of the whole of the chemical exhibits has been accepted by the Association of British Chemical Manufacturers; and now that arrangements are nearing completion, the Association has adopted the courageous policy of giving wide publicity to its doings. Statements have been issued to the Press, and scientific journals with an interest in chemistry have been provided with more detailed information. This has doubtless done much to arouse interest, especially in the scientific world, in the display which is to represent chemistry and chemical industry at Wembley.

The Royal Society's committee on scientific exhibits at the Exhibition is faced with a difficult task. The progress of British science in all its branches, with the exception of chemistry and allied parts of physics, has to be demonstrated impressively and effectively in a space of 2200 sq. ft., by means of a grant from the Government through the Department of Overseas Trade. Here again the field has been divided up into a number of parts, each of which has been put into the hands of an authority. The first classification consists of a primary group (mathematics, astronomy, and physics), and a secondary group (meteorology, geology, metallurgy, engineering, and aeronautics). In each subject there will be (*a*) exhibits and demonstrations illustrating current research, (*b*) instruments, and (*c*) historical material, if space permits. Instruments will be shown mainly from the National Physical Laboratory and the leading instrument makers, while the historical material, consisting of portraits, historical apparatus, and so on, will be drawn mainly from the Science Museum and the Royal Institution.

In organising the pure science exhibit, the aim of the Royal Society's committee has been not to show a mere group of apparatus, but to take some new law or principle, to trace its history, and demonstrate the consequences of its discovery. Thus, to give an example, one series of exhibits will illustrate the discovery and subsequent history of the electron. Starting from the work of Sir William Crookes, illustrated by some vacuum tubes showing the cathode rays and the other consequences of an electric discharge in a vacuum, we shall pass to the researches of Sir J. J. Thomson and the discovery of the electron as a definite entity moving with great velocity, carrying a fixed charge of negative electricity, and having the same mass whatever be its source. This work leads on to the discharge of ions from hot bodies, and the early experiments of Guthrie and the work of O. W. Richardson, on which most of the known laws governing that discharge are based. Then will come the original experiments of Fleming, the phenomena observed in an electric lamp, the discovery of the thermionic valve and its use as an amplifier of wireless waves, and in many other directions.

The National Physical Laboratory is responsible for a section on measuring instruments, illustrating much of its important work in the maintenance of standards of all kinds—thermal, up to temperatures of 2000° C., and electrical, from the currents and voltages used in ordinary practice to those at radio frequency of some 500,000 to the second. On the engineering side there will be exhibits to illustrate recent work on the measurement of stress in solids, the phenomena of fatigue, and the nature of the relative motion of the molecules of a crystal when subject to strain. Wherever possible, the exhibits will take the form of demonstrations, the whole object of the committee being to avoid a "museum" of instruments. The biological exhibits will be selected to indicate some aspects of the progress that has been made in zoology, botany, and physiology, and the varied nature of modern researches in these subjects. There will also be exhibits showing recent results of the study of adaptation, variation and heredity, sex-determination, the physiology of development, etc.

Finally, arrangements are being made for a series of short lectures by scientific workers in connexion with the Exhibition. In short, an attempt is being made to present pure science to the world as a living and progressive subject, and to demonstrate the high value of the work which has been carried out and is still going on in the scientific laboratories of the Empire.

In addition to these purely scientific exhibits, there will be sectional exhibits dealing with the application of science to industry. These will be in the hands of a committee of the Department of Scientific and Industrial Research, acting on behalf of the various Research Associations. Such exhibits will be grouped with their related industries, which will provide the necessary funds as part of their general exhibits. Government research organisations will not have separate exhibits except in so far as they illustrate the working of particular industries such as mining and agriculture; their contributions will go with the pure science exhibit organised by the Royal Society committee.

Reference was made above to what may be termed a Congress Hall, which includes four conference halls with appropriate committee rooms, etc., capable of seating 2142, 550, 180, and 150 persons respectively. A small committee, under the chairmanship of Sir Lawrence Weaver, is making arrangements with various bodies which are organising conferences to be held at the Exhibition. Among the numerous important gatherings which have already been fixed, we may mention the following: an Empire Mining and Metallurgical congress under the presidency of Viscount Long of Wraxall, organised by the Institutions of Mining Engineers and Petroleum Technologists, the Mining Association of Great Britain, the Iron and Steel Institute, the Institute of Metals, and the National Federation of Iron and Steel Manufacturers, to be held during the first week of June; a textiles conference, organised by the Textile Institute, during the second week of June; a World Power conference, organised by the British Electrical and Allied Manufacturers' Association, during the first and second weeks of July; a Museums conference, organised by the Museums Association, during the third week of July; and a conference on Science and Labour, organised by the British Science Guild and the National Joint Council of the Trades Union Congress and the Labour Party, on May 30-31. These conferences will be an important phase in the activities associated with the Exhibition, and the exchange of views promoted will have effects of world-wide significance.

The British Empire Exhibition at Wembley next year will, it is true, be an epitome of the products and the activities of the British Empire. Rightly organised, it can be more. It can show the people of Great Britain, of the British Empire, and, through the numerous foreign visitors it is certain to attract, of the whole world, the progress of industry and the purely scientific work on which all industry is based, in turning to man's need and comfort the natural resources of the world.

Variations in the Level of Lake George, Australia.

On May 18, 1876, a letter appeared in NATURE from Canon R. Abbay on the subject of the changes in level of Lake George, in the south-east of New South Wales, which in the past hundred years has varied from a small swamp to a depth of 25 feet or more. We have now received from Canon Abbay a letter and a diagram showing the variations of level in the lake from 1817 to 1918. The latter, which is reproduced in Fig. 1, was drawn from information compiled by the late Mr. H. C. Russell, Government Astronomer of New South Wales, up to 1904, and since that date by the Commonwealth Meteorological Bureau. It also shows the "residual rainfall curves" for Goulburn, the nearest station, and for Sydney, 150 miles distant. A residual rainfall curve is obtained by finding the difference of rainfall for each year from the average for the whole period and adding up the differences for successive years, so that the figure plotted for any year represents the total excess or deficit of rainfall from the beginning of observations until that year. The curves show, as Canon Abbay points out, that while rainfall is evidently an important factor in the level of the lake, there must also be other influences at work.

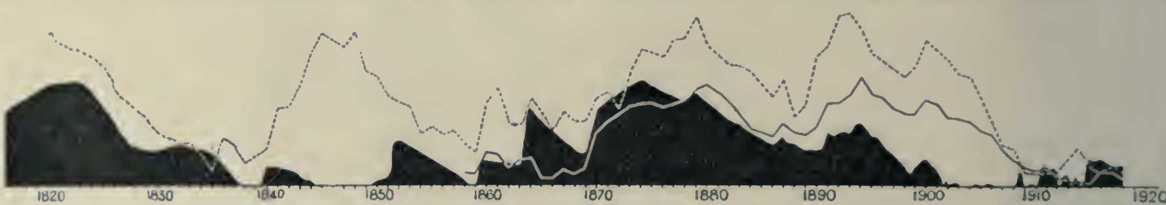

FIG. 1.—Fluctuation of water in Lake George, N.S.W. (Lat. S. 35° 4'; Long. E. 149° 23'). The fluctuations of the water in the lake as shown in black from 1817 to 1904 were compiled from various sources by Mr. Russell, and from 1904 to 1918 by the Commonwealth Meteorological Bureau.

Residual mass curve of Sydney rainfall .... Mean rainfall at Sydney for 76 years, 48·35 in.
Residual mass curve of Goulburn rainfall ———————— Mean rainfall at Goulburn for 60 years, 25·34 in.

The lake is without outlet, and we may accordingly regard its changes of level as determined by the balance between the rainfall and evaporation in its basin, the loss by seepage probably being negligible. As a measure of rainfall the long series of observations at Sydney has been employed from the commencement of the official observations in 1840. The question of evaporation is more difficult, but it has recently been found that in the Central African lakes, Victoria and Albert, the amount of evaporation bears a very close inverse relationship to the number of sunspots, the correlation coefficient between lake level (Lake Victoria) and sunspot number, after elimination of rainfall, being as high as +0·90, and much higher than the correlation with the average rainfall in the basin. In the case of Lake George, a few years of heavy rainfall and slight evaporation result in a considerable rise of level, and if they were succeeded by a series of dry hot years the lake level would fall gradually until it was dry or until another wet period supervened. It was accordingly found best to correlate the changes in level between the beginning and the end of each year (L') with Sydney rainfall (R), and average sunspot number (S), during the same year, and the following results were obtained:

Correlation between change of level and rainfall; influence of sunspots eliminated: $r = +0{\cdot}35$.

Correlation between change of level and sunspots; influence of rainfall eliminated: $r = +0{\cdot}39$.

The regression equation is:

L' (in inches) = 0·96 R (in inches) + 0·43 S (Wolf's No.).

The corresponding equation for Lake Victoria, Central Africa, was:

L (Actual level, inches from base) = 0·36 R + 0·36 S.

The years in which the lake was dry have been omitted from the calculations. The results confirm those obtained from Lake Victoria, that variations of evaporation are probably more important than rainfall variations in determining the level of lakes, and that the rate of evaporation is appreciably greater when sunspots are few than when they are numerous.

The diagram shows that the rainfall at Goulburn agrees fairly closely with that at Sydney, but if the rainfall at several stations over the lake basin had been available for a long period, there is no doubt that the correlation with their average would have been appreciably higher than that with Sydney rainfall. It also appears that the evaporation at Lake George is not determined by sunspots to the same extent as that at Lake Victoria. As Canon Abbay points out, the frequency of west and north-west winds would be of great importance in this connexion, and this would be governed by the pressure gradient between, say, Melbourne and Brisbane.

In 1875 Canon Abbay thought that the rise in the lake, which had proceeded fairly steadily from about 1849 until that date, was connected with the destruction of "bush," allowing the rainfall to run into the basin with little loss, but the subsequent fall in level showed that this could not be the cause, since the destruction of the bush continued while the level of the lake was falling. The nineteen-year periodicity which has been advocated in connexion with Australian weather occurs in the lake levels, though not very definitely, and there is also an eleven-year periodicity connected with the sunspot effect. The two chief maxima in the level, about 1821 and 1875, and the two chief periods when the lake was dry, about 1848 and 1905, are separated by intervals of 54 to 57 years, and may represent a quasi-periodicity of about 56 years caused by the interference of these two periodicities; but weather cycles are treacherous things, and it would not be safe to base a forecast on them. C. E. P. B.

Geological Progress in India.

It is satisfactory to notice that, in spite of financial stress in India, the Government has continued to add to the staff of the Geological Survey, which, with the recruits recently selected, now includes 26 out of the sanctioned 30 officers of the senior grade. The progress of work also during the last few years, since the return to normal duties of those officers who were on active service, has resulted in an approach to completion of many lines of work that had been for some time necessarily left indefinite. Among these the classification of the Tertiary beds of Burma, and their correlation with the Tertiaries of Western India and the standard stratigraphical scale of Europe, are now showing distinct signs of stability.

The untimely death of Mr. E. Vredenburg (NATURE, April 14, p. 505) prevents the completion of the heavy task of summarising the palæontological results, but

the papers which he has published already, together with the work especially of Dr. G. de P. Cotter, are sufficient to permit of a satisfactory classification of the Burma Tertiaries, the correct correlation of which is of great importance to the petroleum industry of the province. Of the distinct steps forward, one of the most important has been recognition of the precise nature of the lateral variation in facies, especially that from north to south, in consequence of the progressive rise and silting of the meridional marine gulf which existed to the east of the Arakan hills in early Tertiary times. Extended mapping of the formations shows how freshwater formations in the north pass southwards into beds of marine origin, while estuarine and littoral beds pass into those of more settled marine origin. The papers of Messrs. Vredenburg and Cotter published in the Records of the Geological Survey (vols. li. and liv.) bring together the main results of this work expressed in tabular form, and additional details have just been issued in a posthumous paper by Mr. Vredenburg (vol. lv., part 1, 1923).

The correlation of the Burma Tertiaries with other areas has been based mainly on marine fossils, but, meanwhile, most valuable studies of the vertebrate remains included in freshwater beds have been carried on by Dr. G. E. Pilgrim. Most of this has been in connexion with the younger Tertiaries of the famous, but, as it proves, not entirely well-known, localities of the west and north-west. Recent work in the Punjab Salt Range shows that some revision of the correlation tables will be necessary, and that it will be possible, when the newly discovered vertebrate remains are studied, to correlate by direct fossil evidence the lower and middle Siwaliks of the Salt Range with those of the Himalayas.

The director's report of the Survey for 1922, just issued by Dr. E. H. Pascoe in the Records, describes, besides a summary of Dr. Pilgrim's most recent work, some interesting results in other parts of India, in addition to those separately noticed in previous pages of NATURE. Among these, an interesting discovery of true Gondwana coal has been made in the Southern Shan States, indicating a Jurassic or Rhætic age, corresponding to a part of the upper division of the Gondwana system in India and some of the coal beds of Tonkin.

Considerable additions have also been made recently to our knowledge of the Deccan trap and of the dykes through which the lava attained the surface. Recent work by Mr. H. Walker in the Tapti valley reveals the interesting fact that the river, for more than 30 miles in an east-west line, follows a fault valley, roughly parallel to the general tendency to rifting which Sir Thomas Holland referred to in his presidential address to Section C (Geology) of the British Association at the meeting in Australia (NATURE, vol. xciv., September 3, 1914, p. 8) as a preparatory condition for the outflow of the Deccan lava sheets.

Another feature of general interest arises from the long-delayed analyses of brines from the Sambhar lake in Rajputana. The economic question which led to a special investigation of this lake 20 years ago arose from the observation of the salt-manufacturing officers that the lake showed signs of depleted resources and consequently possible loss as a source of Government revenue. The investigation undertaken in 1903 by the Geological Survey showed that, while the total amount of sodium chloride stored in the silt rendered nervousness on this account unnecessary, there was a possibility that the continual removal of pure chloride as salt and the consequent increase in the proportion of residual carbonate and sulphate among the soluble salts might increase the difficulty of customary manufacture by fractional crystallisation. A methodical system of sampling was then undertaken annually from various parts of the lake, and Dr. W. A. K. Christie has recently analysed the products. A summary of his results shows that there was a small but definite deterioration in chloride as the result of ten years' work in extracting salt between 1907 and 1916. Taking the two five-year periods to tone out annual variations, the ratio of chloride to other soluble salts in the lake brine has dropped from 86·09 : 13·91 to 85·38 : 14·62. In the brines obtained from the sublacustrine silt the corresponding ratio has fallen from 83·18 : 16·82 to 81·07 : 18·93. Arrangements have been made for resuming the annual sampling of the brines; for unless a system be devised for recovering some of the other salts, the value of the lake as a source of salt will cease long before there is any approach to exhaustion of the total supplies.

Palæontology at the American Museum of Natural History.

THE researches of the palæontological department of the American Museum of Natural History for the years 1918 to 1921 have now been issued as a volume, making the seventh in the series. In all there are twenty-three papers, contributed by Prof. H. F. Osborn, Dr. Matthew, Dr. Gregory, Messrs. Granger, Mook, Von Huene, Miller, Gidley, and Camp. Prof. Osborn describes some new Titanotheres, mostly primitive forms, from the Huerfano, and in two other papers continues his studies on the Proboscidea. One is an account of some American mastodons, and the other is important as giving his views to date on the evolution, phylogeny, and classification of the elephant group as a whole. Dr. Matthew, in addition to faunistic papers, continues, with Mr. Granger, the review of the faunas of the Eocene deposits of the United States. The papers by Messrs. Gidley and Miller are faunistic. There is a series of ten papers by Mr. Mook on crocodiles, recent and extinct; a paper by Mr. Von Huene on reptilian and stegocephalian remains in the Cope collection; and three by Dr. W. K. Gregory, one of them in collaboration with Mr. Camp, which are continuations of his studies on the comparative myology and osteology of vertebrates.

In considering these contributions to our knowledge of palæontology, for the value of which the authors' names are a sufficient guarantee, it will be noticed that the bulk of them are continuations of previous studies, and are designed to attack definite problems. Such, for example, is the series by Dr. Gregory on the muscles and bones, where various parts are compared one by one and worked out in a most systematic manner. These papers will form a mine for other workers. In the same spirit is Mr. Mook's intensive study of the crocodiles and Prof. Osborn's on the elephants.

The volume is a worthy memorial to the energy and devotion of the president and staff of the museum, and the museum without doubt gains from this advertisement of its activity. If the publications by members of the staff of the palæontological department of the British Museum for a similar period were gathered together, it is probable that they would make a worthy companion volume, but, being widely scattered in several publications, the public has never the opportunity to discover this fact.

It may further be noted that, in the period covered by these communications, the American Museum from its palæontological department alone sent six expeditions into the field as far as China, India, and Cuba, as well as in the States themselves.

University and Educational Intelligence.

BIRMINGHAM.—The degree of D.Sc. has been conferred on Mr. C. S. Fox for a thesis on "The Bauxite and Aluminous Laterite Occurrences of India," and supplementary papers; and on Mr. B. M. Griffiths for a thesis on "The Phytoplankton of Bodies of Fresh Water, and the Factors determining its Occurrence and Composition," and supplementary papers.

CAMBRIDGE.—Mr. S. W. P. Steen has been elected to a fellowship at Christ's College.

The secretaryship of the Board of Research Studies has become vacant by the resignation of Sir Geoffrey Butler, now elected representative of the University in Parliament, who has done valuable work in steering the new scheme for the Ph.D. degree successfully past certain initial difficulties.

It is proposed, subject to the approval of the Statutory Commissioners, to bring all University officers appointed in the future under such pension scheme as shall be adopted by the University and approved by the Commissioners; and further, for the University to take powers to come to an agreement with present holders of University offices whereby they may come under the general pension scheme.

It is proposed to admit to the privileges of affiliation graduates of certain other universities who have graduated with first-class honours without the present restriction that they must have passed in English, mathematics, and Latin or Greek at one of the examinations leading to their present degree.

EDINBURGH.—On Monday afternoon, December 10, the Rt. Hon. S. M. Bruce, Prime Minister of the Commonwealth of Australia, visited the University and received the honorary degree of Doctor of Laws. Mr. Bruce was warmly received, especially by a number of Australian students, who formed a compact section of the audience and who gave their distinctive call. In a speech immediately following the ceremony Mr. Bruce emphasised the great need they felt in all the Overseas Dominions that men of university training should take increasing interest in the affairs of their respective countries. At no time in the history of Great Britain or the Empire as a whole had it been more imperative that they should have these men, with all their traditional ideas gathered in the university, to give of their services freely and willingly to the country and to set a standard of good citizenship. He appealed for renewed unity of the people, and said that "a strong and united British Empire is the greatest hope there is to-day for the future peace of the world and for the happiness and security of the whole of humanity."

SHEFFIELD.—The following appointments have been made: Mr. R. A. Morrell, to be lecturer in radiology; Mr. G. Wilkinson, to be lecturer in the history of medicine; and Dr. D. C. Barron, to be assistant-lecturer in medicine.

LONDON.—The following doctorates have been awarded: *Ph.D.* (*Science*): Prabhatchandra Sarbadhikari (Imperial College—Royal College of Science) for a thesis entitled "Cytology of Osmunda and Doodia—On the Somatic and Meiotic Mitosis of Doodia—I"; Mustapha Ahmed Abu Zahra (Imperial College—Royal College of Science) for a thesis entitled "The Mechanical and Graphical Solution of the Two-dimensional Motion of a Cylinder of a General Section in Viscous Fluid subject to Oseen's Approximation"; Hassan Sadek (University College) for a thesis entitled "Miocene Period in the Gulf of Suez Area, Egypt." *Ph.D.* (*Economics*): Emma Annie Winslow (London School of Economics) for a thesis entitled "Budget Studies and the Measurement of Living Costs and Standards."

MR. E. C. DAVIES, a distinguished student of Prof. R. M. Wild at the University of Manchester, has been appointed assistant lecturer in chemistry at the Natal Technical College, Durban, S. Africa.

SINCE our issue of December 15 the following announcements of the election of representatives of the Universities in Parliament have appeared: Oxford—Sir Charles Oman (U.) and Lord Hugh Cecil (U.); Wales—Mr. G. Davies (Lab.).

APPLICATIONS are invited by the committee of the University College Hospital for the Radcliffe Crocker travelling scholarship in dermatology, the approximate value of which is 280*l.*, tenable for a period of twelve months, to be spent at some place of study outside the United Kingdom. Further particulars may be obtained from the Dean, University College Hospital Medical School, University Street, W.C.1.

THE New York correspondent of the *Times* states that Mrs. Montgomery Ward has given 3,000,000 dollars (about 660,000*l.*) to the North-Western University, Chicago, to create a medical centre at the University to be called the Montgomery Ward Memorial. Yale University has announced that 4,000,000 dollars (about 880,000*l.*) of the 15,000,000 dollars (about 3,330,000*l.*) left to it by the bequest of John W. Sterling will be used to erect a library.

RECENT progress in vocational education in America is described in the sixth annual report of the Federal Board for Vocational Education. The enrolment in schools aided by the board has increased steadily from 164,000 in 1918 to 475,000 in 1922, in which year their total expenditures amounted to 12½ million dollars. The outstanding feature of this development has been the growth of the general continuation schools. The main purposes of this type of school are the same as those of the continuation schools provided for by Mr. Fisher's Education Act of 1918. Of the 48 states, 43 now maintain part-time schools for young persons who have left full-time schools to go to work, and 21 have enacted state-wide mandatory or permissive part-time school laws. Although the enrolment in schools of this type has increased from 53,000 in 1918 to 228,000 in 1922, this number is less than one-tenth of the boys and girls 14 to 17 years of age not attending school of any kind. One notable aspect of recent progress in the vocational school movement is its influence on the regular public day schools: "There is a new spirit in elementary education; it is the spirit of attention to practical needs." Conversely the outlook of the vocational education programme is being broadened so as to include much more than simply "specific preparation" for the technical processes of a skilled trade. Some idea of the extent to which employers recognise the value of continuation schooling may be gathered from the fact that at least 25 national associations of employers have set up organised systems of training for employees, some with endowments ranging from 2 to 10 million dollars. The Federal War Department has developed an elaborate system of testing for and teaching trades in the Army, based on a policy of fitting men not only for effective military service but also for success in civil life.

Societies and Academies.

London.

Aristotelian Society, November 26.—Prof. H. Wildon Carr in the chair.—J. W. **Scott**: The incidence of mathematico-physical speculation on philosophy. Mathematical speculation upon philosophical questions is especially forceful at two places—the theory of the infinite and the theory of appearances and their relation to reality. The naïve conception of the infinite has been a common problem for philosophers and mathematicians alike. Kant declares that we can prove with equal cogency that space or time both must be and cannot be infinite; and Galileo points out that an infinite number is a number such that the number of numbers making it up is the same as the number of numbers making up a contained part of it. Philosophers and mathematicians alike do not stop at the difficulty of the naïve conception. For each there is a false as well as a true conception of infinity, and their definitions are curiously alike. The essence of infinity consists for the mathematician in a certain relation between the whole and its parts, and for the idealist philosopher infinity is only to be ascribed to wholes which are self-contained, such as works of art. The other problem, namely, the problem which of the contradictory appearances of a sense-perceived object is the real appearance of the thing, may be solved along the same lines. Perspectives sum into a container. The unity either of a thing or of a sensum is the unity of an infinitude; and an infinitude is something in some sense self-contained.

December 3.—Prof. T. P. Nunn, president, in the chair.—Dorothy **Wrinch**: On certain aspects of scientific thought. Many important scientific hypotheses embody the assumption that certain properties are irrelevant to each other. They may be grouped together as "irrelevance postulates." Thus in the quantum theory there is an important hypothesis to the effect that the energy of a bundle of radiation given off by an atom of matter to the ether, divided by the frequency with which it manifests itself to the spectroscope, is always an integral multiple of a universal constant h. The assumption states that this ratio h has the same value, irrespective of all physical and chemical properties of the matter which emits the radiation. Also other "constants of Nature" such as the charge carried by an electron, the velocity of light, the universal constant of gravitation, correspond each to a "postulate of irrelevance." Einstein has suggested a postulate of irrelevance of a still more radical kind in his assumption that the laws of Nature are invariant with respect to systems of co-ordinates which satisfy certain very general conditions. In the generalised theory of relativity these are the Gaussian systems.

Royal Anthropological Institute, November 27.—Mr. H. J. E. Peake in the chair.—E. H. **Hunt**: Hyderabad cairn burials and their significance. Cairn burials with stone circles are found scattered over the whole of South India. Their numbers indicate that important persons alone could have received this form of burial, and the civilisation represented must have held full sway for a prolonged period. Pots are found inside and outside cists. Body positions are commonly "contracted," though "extended" and "urn" burials are found, and burnt bones. Iron is found constantly, but iron affords no evidence of date in India. Surface denudation of more than fifteen feet of hard soil in places and disintegration of granite slabs in the absence of salt afford evidence of considerable age. History shows that these burials cannot date later than Asoka in any case. Vedic writings are silent. There is a curious series of similarities with early Egypt: (1) Cultivation by irrigation; (2) orientation of graves; (3) burials; (4) polished black and red pots, red pots on ring stands, and pot marks, *e.g.* the "KA" mark; (5) lapis beads, a stone foreign to Egypt, and probably also to India. Parallel with these resemblances an equally striking series of differences can be made out, such as the absence of stone circles in Egypt, though boulders abound.

December 4.—H. **Balfour**: On certain aspects of the technology of the Nagas of Assam. The field-observations recorded were made during a three-months tour through the Naga Hills in company with Messrs. J. H. Hutton and J. P. Mills, resident officials of the I.C.S., in the winter of 1922, during which some 50 or 60 native villages were visited. The prevailing system of "dry" cultivation by *jhuming*, as contrasted with the elaborate intensive system of "wet" terrace-cultivation practised almost exclusively by the Angami, has had devastating effects upon jungle-growth. Among the Ao Nagas, when fire-making is practised for divination or taking omens, it is not necessary to obtain a spark. The ordinary process is followed of sawing a bamboo thong round a stick, but the latter need not be split as it invariably is for ordinary fire-making. When the thong breaks the broken ends are carefully studied, and the omen is taken from the nature of the fracture. This use of an *unsplit* stick for divination has not before been recorded. A type of fish-trap is used, not before described from the Naga Hills, the chief interest of which lies in its almost continuous dispersal from this area through the Malayan and Indonesian regions to Melanesia, affording a valuable culture-link between the extremes of its geographical range. This culture-link is further emphasised by the loom and by other items, which together throw light upon the route followed by culture-dispersal within this wide area. The carved "figure-heads" embellishing the huge monoxyle dug-out gongs of the Ao Nagas are conventionalised representations of the head of the water-buffalo. An account was given of "bull-roarers," recently discovered by Messrs. Hutton and Mills to exist in this region.

Royal Microscopical Society (Industrial Applications Section), November 28.—Sir Kenneth Goadby in the chair.—J. E. **Barnard**: The characteristics of a microscope for general and special purposes. The tests for mechanical efficiency that should be satisfied.—S. H. **Browning**: The application of the microscope to industrial diseases.—C. A. **Newton**: The microscope in the examination of condensed milk. If a film of sweetened condensed milk be examined at a magnification of from 50 to 100 diameters, the sugar it contains can easily be seen. The sugar crystals afford an indication of the good quality of the milk; if they appear clean and well defined, the milk will keep well, while in bad milk, or milk likely soon to become bad, there appears also an acicular crystallisation of the milk sugar. Sweetened condensed milk in its normal state is too dense or too opaque for examination by the higher powers of the microscope necessary to observe any micro-organisms likely to be present. Diluting with nine parts of distilled water, a thinner film is available, and in the case of bad milk it is then easy to see yeast cells (causing milk to become "blown"), and other micro-organisms if any are present.

Linnean Society, November 29.—Dr. A. B. Rendle, president, in the chair.—C. C. **Lacaita**: The Onosmas of Linnæus and Sibthorp, with a note on those of

Tournefort's herbarium.—M. D. **Zalessky**: On new species of Permian Osmundaceæ. An extension of Kidston and Gwynne-Vaughan's work on the anatomy of Permian Osmundaceæ from Russia. Ferns of this affinity in Permian times had a solid wood in the stem, differentiated into an outer zone of normal tracheides and an inner core of short, wide elements The leaf-trace, on its outward course, changes from mesarch to endarch structure. The anatomy is described in *Bathypteris rhomboidalis* (in which the stele was previously unknown), in two new species of Thamnopteris (*T. Kidstoni* and *T. Gwynne-Vaughani*), and in a new species of Zalesskya (*Z. uralica*) which may be a young state of *Z. gracilis*.—C. L. **Withycombe**: On the function of the bladders in *Utricularia vulgaris* Linn. The bladders are not passive traps, but capture prey by active movement in response to stimuli. The valve is a continuation of the wall; it is two cells in thickness, and closes the mouth completely when its free margin is applied to the collar. It consists of three ill-defined regions; marking the third or marginal flap are four tapering bicellular hairs which are sensory. The quadrifid hairs lining the bladder constantly absorb the fluid within, until equilibrium is reached between the internal negative pressure and the osmotic tension which can be exerted by the cell contents of the hairs. There is now a considerable tension upon the valve, tending to pull it inwards. This is prevented by a cushion of specialised cells within the collar. Only an upward movement can possibly release the valve from its catch, and this is brought about by touching ·he sensory hairs.

Eugenics Education Society, December 14.—Prof. E. W. MacBride in the chair.—A. S. **Parkes**: Some aspects of reproduction considered in relation to eugenics. Inherent constitution is of prime importance from a eugenical point of view, but the conditions under which reproduction takes place may have the effect of limiting or augmenting the development of the hereditary qualities. If reproduction takes place under bad conditions, the fullest expression of the inherited characteristics will be hindered. Conditions obtaining during the maturation of the germ cells and during the gestation of the fœtus constitute the most potent of environments. The age of the mother is probably one of the most important factors governing the efficiency of the secondary sexual organs of the female for reproduction, and this is especially true of first births. The optimum age for reproduction seems, in the female, to be between twenty and thirty years, and first pregnancies occurring much after this age are attended by great probabilities of mishap.

CAMBRIDGE.

Philosophical Society, November 12.—Mr. C. T. Heycock, president, in the chair.—P. **Lake**: Wegener's theory of continental drift.

November 26.—Mr. C. T. Heycock, president, in the chair.—J. **Barcroft** and H. **Barcroft**: The hæmoglobin of Arenicola. The α band of oxy-hæmoglobin in Arenicola is 18 Ångström units nearer the blue than in human blood, and the α band in carboxy-hæmoglobin 12 Ångström units nearer the blue than in man. The pigment in Arenicola has a greater affinity both for oxygen and carbon monoxide than in the mammalia. The oxygen capacity in Arenicola is approximately 0·01 c.c. of oxygen per hour, an amount which is of the same order as that necessary to maintain the respiration of the worm whilst its hole is closed at low water.—C. **Shearer**: Direct measurements of axial gradients in embryonic tissue.—J. B. S. **Haldane**: A mathematical theory of natural and artificial selection. Pt. I. The effect of selection on the composition of Mendelian populations in certain simple cases is investigated by means of finite difference equations. Selection produces little change in the population when the recessives are few in number, except in the cases of inbreeding, assortative mating, and sex-linked inheritance.—H. Munro **Fox**: (1) The spawning of echinoids. The extrusion of the genital products of echinoids is due to the contraction of muscle fibres in the gonad walls. The contraction of these muscles can be artificially stimulated and spawning thus induced. A spawning male stimulates ripe individuals of both sexes which are in the neighbourhood to spawn. After spawning, *Strongylocentrotus lividus* re-forms ripe eggs in nine days at a temperature of 17°-19°. (2) The migration of a Red Sea crab through the Suez Canal. *Neptunus pelagicus* commenced to migrate through the Suez Canal in 1893, twenty-four years after the canal was opened, and reached Port Said in 1898. The crab has now spread along the Mediterranean coasts to Alexandria and to Haifa.—N. J. G. **Smith**: The parasitism of *Helminthosporium gramineum* Rab [leaf-stripe disease of barley]. This fungus produces leaf-stripe disease without being present in the growing-point, and it causes death if that point is reached. The fungus penetrates each young leaf (and finally the chaffs of the developing ear) from the enveloping sheath, the first sheath being infected from conidia, mycelium, or perithecia borne on the seed or elsewhere.—R. N. **Salaman**: A leaf index as a help to the identification of potato varieties. The first lateral leaflet on the left of the midrib of each leaf is measured, and its index $\frac{\text{breadth}}{\text{length}} \times 100$ calculated. The leaf index of a variety must be ascertained from adult leaves on a healthy plant. The variation of the index within any given variety is a normal one and represented by a normal frequency curve. The probable error of the difference of two means of 20 each is 0·7. A difference of two units in the index may be considered as of significance. Of 65 varieties of which the index was measured, the value of the latter varies between 50 and 72. Neither the place of origin of seed tubers, nor the locality where the plants are raised, has any effect on the leaf index, provided that the plants are healthy. The leaf index is a constant for each variety.

DUBLIN.

Royal Dublin Society, November 27.—Prof. E. A. Werner in the chair.—F. W. R. **Brambell** and J. B. **Gatenby**: On the supposed homology of the Golgi elements of the mammalian nerve cell, and the nebenkern batonettes of the genital cells of invertebrates. The Golgi apparatus in the smallest neurones of Helix is in the perinuclear extra-centric position, surrounding an archoplasmic sphere. In larger neurones it becomes dispersed around the nucleus and the individual elements become much more numerous. Basophil granules, probably representing the tigroid body, and also lecithin (?) granules, are described in the neurones. In silver preparations dark zones are found around the Golgi elements. These probably represent a product of its activity. Long and sometimes branched Holmgren canals were found in the neurones. They were separate and distinct from the Golgi elements. They may be processes of the subcapsular cells. From the position occupied by the apparatus in nerve and germ-cell, from its similarity of micro-chemical reaction in both, and from embryological evidence, it is believed that the nebenkern batonettes of the invertebrate germ-cells are homologous to the Golgi network of the mammalian neurone.

—H. H. **Dixon** and N. G. **Ball**: On the extraction of sap from living leaves by means of compressed air. Branches of *Tilia americana* and *Sambucus nigra* were enclosed in a strong cylinder in such a way that their cut ends protruded. Compressed air at pressures up to 20 atmospheres was admitted into the cylinder, and the liquid which exuded from the cut end of the branch was collected. This liquid was found to be completely, or almost completely, free from sugars. Experiments carried out in early and late summer gave similar results. After the leaf cells had been made permeable by means of toluene vapour the sugar in the expressed sap amounted to about 5 per cent.—H. H. **Poole**: Some experiments on the convection of heat in vertical water columns. Experiments are described on the convection of heat in single and also in double vertical water columns. In most cases, the flow of heat increases much more rapidly than the temperature gradient. The smaller the column the more rapid is the rise of heat flow with rise of gradient. It is concluded that, for the small gradient existing in the earth the effect of convection in water-logged porous rocks would be negligible. Where, however, water-filled fissures occur, we should expect an appreciable increase in the vertical flow of heat.

Royal Irish Academy, December 10.—Prof. Sydney Young, president, in the chair.—J. B. **Gatenby**: Notes on the human ovary, with special reference to the corpus luteum of ovulation. The minute cytology of the lutein cells of the human corpus luteum is described. There is a Golgi apparatus larger than the nucleus; the lutein granules are not true fat, but are probably the mitochondria loaded with lipochrome. A new type of cell is described, called the stellate chromophil cell, probably the homologues of the clasmatocytes of areolar connective tissue. Possible cytological criteria for distinguishing between the corpus luteum spurium and verum are given.

EDINBURGH.

Royal Society, December 3.—James **Chumley**: Deep-sea deposits of the Atlantic Ocean. This detailed research was based on a large series of deposit-samples (1426 in number) collected from the floor of the Atlantic by thirty-five expeditions between 1857 and 1911, varying in latitude from 50° S. to 60° N., and in depth from 110 to more than 4500 fathoms. The examination of these materials was in progress at the *Challenger* Office, Edinburgh, under the superintendence of the late Sir John Murray at the time of his death in 1914. Mr. Chumley, who was associated with Sir John Murray for a number of years as assistant, has finished the descriptions and worked up the results in accordance with the methods established by him. There are detailed descriptions of 1426 samples, which cannot fail to be of signal service in any future oceanographical work in the Atlantic. The descriptions are followed by a discussion of the information furnished as regards (1) the various types of deposits, (2) the distribution of the different constituents entering into the composition of the deposit.

MANCHESTER.

Literary and Philosophical Society, December 4.—W. B. **Wright**: The search for concealed coalfields in the north of Ireland. Valuable areas of unworked coal exist beneath the cover of the newer rocks in the counties of Antrim and Tyrone. The structure of the area covered by the newer rocks is controlled by a series of direct and transverse troughs at the intersection of which the deepest basins occur. As there is a considerable amount of evidence indicating that these basins are more accentuated in the older rocks below than in the overlying cover, they are very likely to contain the coal measures, which form the upper member of the older series. The margin of one of the coalfields so indicated is in fact visible at Coalisland, Co. Tyrone, where the newer rocks have been removed by denudation, and this is now being worked by Sir Samuel Kelly some little distance in from the outcrop. An exceptionally rich series of coals have been penetrated and a large output is confidently predicted.

SHEFFIELD.

Society of Glass Technology, November 21.—H. S. **Houldsworth**: Note on the influence of rapid chilling on the reversible expansion of clay. The phenomena cited are consistent with the explanation that solution of free silica occurs at the higher temperatures of heating, that this separates out as cristobalite or tridymite on slow cooling. It does not so separate on rapid cooling. Some imperfect separation is likely, but not in a sufficiently definite form to be able to exert its proper influence on the expansion phenomena.—P. **Marson**: Glasshouse pots: some notes on their manufacture and use. The mixing, weathering, and preparation of the clays were described. Pots which have been stored for a long period after drying give more trustworthy results than new pots used shortly after drying. Of faults which develop in the drying room the chief are cracks across the bottoms of the pots and drying cracks along the angles inside. Nine days should be occupied in heating up large pots in the pot arch. After setting, the pot should be left to mature in the furnace for not less than 48 hours before filling on.—Kurd **Endell**: The casting process for glasshouse refractories in German glass plants. Tests show that cast pots are denser than hand-made ones. Cast pots are chemically more resistant than hand-made pots, and there is no perceptible difference between them in respect of heat resistance.

CALCUTTA.

Asiatic Society of Bengal, November 7.—N. **Annandale**: Aquatic gastropods. (Zoological results of the Percy Sladen Trust Expedition to Yunnan in 1922.) The most remarkable feature of the water-snails of the province of Yunnan, particularly those of the great lake Erh-hai, is the close resemblance between many of the shells and those of certain tertiary beds in Central Europe. Definite relations exist between these shells and those of the tertiary beds of the Shan plateau, but the resemblance between the Chinese and the European species is due to the convergent evolution.—W. M. **Tattersall**: Crustacea Amphipoda. (Zoological results of the Percy Sladen Trust Expedition to Yunnan in 1922.) Two specimens of Gammarus were collected, *G. annandelei* recently described from eastern China and Japan, and a new species allied to *G. crassus* from the Caspian Sea.—R. B. **Seymour Sewell**: Geographic and oceanographic research in Indian waters. (1) The geography of the Andaman Sea basin. The basin bounded by the Nicobar-Andaman ridge and the ridge itself are of composite character. A barrier-reef of coral exists on the western side of the ridge. (2) A study of the nature of the sea-bed and of the deep-sea deposits of the Andaman Sea and the Bay of Bengal. Charts are given showing the nature of the deposits at different points, the limits of the deposits of mud brought down by the great rivers, and the influence of currents on the bottom. (3) The density and salinity of the waters of Indian seas.

(*a*) The South Burma coast and Mergui Archipelago. The distribution and oscillation of salinities and densities off the coast of Burma at different seasons and times of day and the influence of air temperature, winds and other factors on the density of the surface water are discussed.—Sat Kori **Dutta**: On a peculiar disposition of the liver and the kidney in the genera Clarias and Saccobranchus. R. C. **Majumdar**: The date of the Khaḍga dynasty of Bengal. Hitherto the date has been unanimously read as year 13. The numerical figures should be read as 79 or 73. Referring this year, 79 or 73, to the Harsha era, a date is obtained for the Khaḍga Kings in the 7th century A.D., and this date is corroborated by some Chinese accounts of the political conditions of Samataṭa towards the close of the 7th century A.D.

CAPE TOWN.

Royal Society of South Africa, September 26.—Dr. A. Ogg, president, in the chair.—J. D. F. **Gilchrist**: On a protozoal parasite of the snoek, *Chloromyxum thyrsites*, sp. n. The Cape "snoek" and the Australian "barracouta" (*Thyrsites atun*) show a softening or liquefaction of the muscular tissue, caused by a protozoal parasite resembling Chloromyxum. The spore is quadriradiate, about 12×8 microns, has four polar capsules, and only four distinct nuclei were seen. The trophozoite is unicellular increasing by schizogeny or simple fission, and is usually intercellular. Each trophozoite produces a single spore.—B. F. J. **Schönland**: Note on cathode ray absorption. The theory of absorption due to Bohr is in good quantitative agreement with new measurements of the absorption of cathode rays by matter. In applying the theory to measurements of the decrease of velocity of rays in passing through matter, Bohr has deduced the relation $(V_0 - V)V_0^3 = ct$, where V_0 = initial velocity, V = final velocity, t = thickness, c = constant. Existing measurements have all been put in the form $V_0^4 - V^4 = Kt \ldots\ldots (2)$. This last equation reduces to Bohr's form in the case where V and V_0 are nearly equal. The value of c for aluminium deduced from Terrill's observations is $4 \cdot 0 \times 10^{42}$, while that calculated from Bohr's theory is $4 \cdot 1 \times 10^{42}$.—Joseph **Kürschák**: On matrices connected with Sylvester's dialytic eliminant.

SYDNEY.

Linnean Society of New South Wales, September 26.—Mr. J. J. Fletcher, vice-president, in the chair.—A. J. **Turner**: A revision of the Australian Anerastrianæ (Lepidoptera). Only five Australian genera, which can be easily tabulated, namely, Statina, Calamotropa, Emmalocera, Anerastria, and Saluria, are recognised. Four species are described as new.—C. T. **White**: A new conifer from Southern Queensland. Description of a new species of Callitris, close to *C. calcarata* R.Br. but easily distinguished by the characters of the cones.—R. **Greig-Smith**: The high temperature organism of fermenting tan-bark. Pt. iii. The organism produces carbon dioxide from a number of carbon compounds. These include carbohydrates such as saccharose, dextrose, levulose, maltose, lactose, galactose, xylose, dextrin, starch, gum acacia; alcohols such as mannit, glycerin, amyl, and ethyl alcohols; salts of organic acids such as citric, lactic, succinic, acetic; nitrogenous substances such as peptone, asparagin, meat-extract. Ammonium salts and urea can serve as sources of nitrogen. Raffinose and inulin are scarcely fermented. Oxalates and formates are not attacked.—T. **Steel**: On some abnormal sugar-canes. A series of abnormal sugar-canes grown in Australia is figured and described, comprising examples of forking, multiple and suppressed budding, peculiar joints and regularly malformed joints. It has been observed in Australia that while striped canes grown from "sets" reproduce the characters of the parent cane, seedlings from similar canes are always plain without stripes. This may indicate reversion to an original stripeless cane. Wild native cane in Fiji is always either red or yellow but has no stripes.—A. M. **Lea**: On some Australian Galerucides. These are small but destructive leaf- and flower-eating beetles. Ninety-three species of the genera Monolepta and Candezea are described as new.

Royal Society of New South Wales, October 3.—Mr. R. H. Cambage, president, in the chair.—M. B. **Welch**: (1) The secretory epidermal cells of certain Eucalypts and Angophoras. The elastic covering of rubber found on the young leaves of many of the Eucalypts and the closely allied genus, the Angophoras, is secreted by the outer or epidermal cells, which are of a peculiar shape. This covering acts as a very efficient means of reducing evaporation from the leaf; and the fact that only the more primitive species possess it, seems to indicate that originally the Eucalypts were exposed to much greater extremes of temperature than at present. (2) Note on the effect of temperature on borers attacking seasoned and unseasoned timber. Owing to the difficulty experienced in getting any liquid to penetrate more than a fraction of an inch into sound timber by ordinary methods of application (with the exception of certain of the softer pines and brush timbers), it is not easy to rid infested timber satisfactorily of the borer pest. Where timber is badly attacked there is far greater opportunity for any deterrent liquid to penetrate. A method of eradication which has been tried successfully is the application of heat. A temperature of about 113° F. for one minute in moist air is usually sufficient to kill the borer.—W. L. **Waterhouse**: Note on the occurrence of double embryos in wheat grains. Amongst germinating wheat grains of the varieties Tandilla King and Federation, two grains were found, each having two embryos. Each gave rise to two shoots and six seminal roots. The seedlings are growing, and further studies are projected if grain is produced.

Government Publications and their Distribution.

WHEN a government takes in its own hands the publication of matters of scientific interest, it may be assumed that this is done with three distinct objects in view. In the first place, it wishes to bring to the notice of scientific workers the results of original researches carried out by experts in Departments under its control, in order that these results may form a foundation for further advance in knowledge. So are published the papers comprised in the excellent scientific reports of the Ministry of Agriculture and Fisheries in England, and of the Fishery Board for Scotland. Or it desires to bring to the notice of the public, for the sake of the individual and through him of the nation at large, the condensed wisdom of science as bearing upon matters of practical importance. Such is embodied in the pamphlets and leaflets dealing with agricultural pests and plant diseases, with methods of land-cultivation and stock-raising, issued by the Ministry of Agriculture and Fisheries and the Board of Agriculture for Scotland. Sometimes these two aims are seen to run side by side, as in the Journals of Agriculture published both by the English Ministry and Scottish Board, in which matters of both scientific and practical interest appear.

The third object is very different from either of the above, its end being to inform the outside world, scientific and non-scientific, regarding the activities of institutions in which a general interest is taken ; it takes its typical form in the annual reports of such establishments as the British Museum, the Natural History Museum, and the Royal Scottish Museum. This last object may seem to have little of scientific value to commend it, but it is in reality of prime importance; for institutions of the kind mentioned depend for many of their most valuable acquisitions upon the generosity of the public, and unless public interest is stimulated by full knowledge of progress and requirements, the national collections, and science, must in the end suffer.

The duty of scientific publisher assumed by the Government does not end, however, with the printing of pamphlets, nor are its aims thus attained ; the question of distribution is second only to that of printing, and it is to this that we wish particularly to direct attention. Every scientific worker is aware of the generous and even lavish free distribution of scientific publications carried out by Government Departments of the United States of America ; and one is tempted to speculate whether the activity and originality of research now apparent there may not be due in part to this sustained appeal to the scientific mind.

At no time could H.M. Government have been charged with a lavish or even generous distribution of the scientific fruits its workers have culled. It now appears that even the meagre distribution of former years is to be curtailed, and a false notion of economy threatens practically to abolish the free circulation of government publications of scientific interest. The new policy affects the three types of publications already mentioned in various ways.

In recent years, the annual reports of the Museums have dwindled until they have become dry skeletons, scarcely worthy of distribution, and quite unworthy of the great national institutions they represent. Compare them with the beautifully printed and illustrated reports of the American State Museums. Surely this is not the way to encourage the free giving of the public, on which the American Museums and our own so largely depend.

The leaflets of the English and Scottish Departments of Agriculture were formerly sent gratis on publication, from a standing list, to gardeners, farmers, and others interested in the checkmating of pests or the improvement of cultivation, and the wide distribution of these concise and generally up-to-date publications played a great part in combating local pests, and possibly in preventing the local pest from becoming a national pestilence. Now, to be received free each leaflet must be applied for in writing, and only one copy of any one leaflet is supplied gratis: the free circulation as a matter of routine has ceased.

As regards research publications, the position is no less serious. Here also free distribution to workers interested in like fields has ceased, and scientific societies no longer receive copies in exchange for their own publications. Yet, curiously enough, the scientific worker in foreign countries is to be given a preference denied to his British colleague, for foreign societies making exchanges are not to be placed under the ban.

A still further restriction has been brought into force. The circulation of the records of scientific discovery has always been greatly aided through the strictly discriminate distribution, by the discoverer himself, of author's separates; and most scientific journals are still willing to present an author with twenty-five copies or so of an original contribution. But personal application to government scientific workers for a particular separate has disclosed the fact that, at any rate in certain important scientific departments, the allowance of author's reprints granted by Government is limited to *three* copies, though indeed if the published price of the pamphlet be less than one shilling he may have six. A joint author, provided he has contributed more than a third of the research, is entitled to one-third of this normal allowance. Could cheese-paring be more ridiculous?

It would seem that, in the desire to save a mite, the Government is in danger of losing a mountain. The cost of a relatively small number of off-prints, once the type has been set up, can scarcely be compared with the gain likely to accrue from a wide circulation of scientific matter of practical and economic importance; and in this respect the Government has duties to the public and the scientific world other than those of a publisher controlling a purely commercial undertaking. As the matter stands, government researches will continue to be made, and the results laboriously gained by trained and expert workers will be printed at very considerable cost—and then consigned to oblivion in the cold storage chambers of H.M. Stationery Office or some other department.

There is no suggestion here that the Government should undertake wasteful distribution. It has always seemed to us unnecessary that when an allotment-holder applied for agricultural leaflets, having in mind garden pests, he should receive also instruction in pig- and poultry-keeping, in the values of farm manures, or in the financial affairs of agricultural co-operative societies. But this danger might be avoided by, let us say, grouping the leaflets for free distribution in distinctive and homogeneous sections for particular classes of inquirers, rather than by the drastic step of abandoning altogether the method of free routine distribution. Perhaps, short of the generous distribution of scientific papers with which the United States have made us familiar, something might be done by the wide circulation of the periodical H.M. Stationery Office lists of Government publications, from which scientific societies or interested individuals might select and apply for such works as concerned their own field of activity.

In any event, the distribution of Government publications dealing with matters of scientific interest cannot remain as it stands at present; it is based upon a narrow idea of the importance of the spread of scientific knowledge, even upon a mistaken computation of the pecuniary value of science. How diametrically opposed it is to the trend of enlightened opinion in Great Britain is indicated by a recent decision of the Carnegie United Kingdom Trustees to increase still further their free circulation of expensive books to whatsoever individuals care to take up any serious study. What is wanted is not less facilities for making scientific knowledge and achievement widely known, but more. It is to be hoped that scientific societies will not permit the recent restrictions to pass unchallenged, and will unite to secure for the public and for scientific workers the fullest publicity for information of service to them as stimulus or as guidance.

The Physiology of Sex-Determination.

The Mechanism and Physiology of Sex Determination. By Richard Goldschmidt. Translated by Prof. William J. Dakin. Pp. ix + 259. (London: Methuen and Co., Ltd., 1923.) 21s. net.

PROF. GOLDSCHMIDT gives us an object-lesson in the way in which a single problem, at the outset not apparently more important than a thousand others, may, if pursued to its limit, be made to yield results of the deepest importance and the widest application.

It has long been known to entomologists that crosses between different species, and often also races, of Lepidoptera frequently produce a number of sexually abnormal forms. This was the starting-point of the investigation which has finally enabled Goldschmidt to make his important contribution to the study of sex-determination, and indeed to the problems of differentiation in general.

Put in the briefest possible way, we may sum up the results of his twelve years of work upon the sexual abnormalities arising in racial crosses of the Gipsy moth (*Lymantria dispar*) as follows. In the first place, since moths have two active sex-(X-)chromosomes in the male, and one in the female, the male-determining factors are in double dose in males, single dose in females. The female-determining factor Goldschmidt has finally located in the Y chromosome—an interesting fact, since the work of the Morgan school on Drosophila has shown that there the Y chromosome is without influence upon sex-determination. He has next shown that the strength or "potency" of the sex-determining factors may vary, and does actually do so in the different sub-species and races employed. It follows that when a cross is made, the future distribution of the sex-factors of various strengths, both male- and female-determining, can be prophesied from what we know of the behaviour of the chromosomes, or, in other words, on Neo-Mendelian principles.

As to the mode of action of the female-determining factor, we have the important fact that the Y must exert its effect upon the growing oocyte, since we find that the female-determining factor (which is inherited purely maternally according to expectation) is effectively present in males as well as females, although, of course, in all eggs destined to give males the Y has been eliminated in the polar body. If we are to draw conclusions, it appears that some substance, which Goldschmidt considers as of enzymatic nature, is given off into the oocyte in quantity proportional to the "potency" of the female-determining factor in the Y, and exerts effects in embryonic development proportional to its quantity. It is clear that if this is fully substantiated, it gives us important clues as to the possible mode of action of chromosomal genes.

By these last facts we are introduced to the second part of the problem—the mode of action of the sex-factors during development in contradistinction to their distribution to the gametes and zygotes—a field where Goldschmidt has made his most signal contribution. What do we start with?—the presence in every male moth of two doses of male-determining, and one dose of female-determining substance; whereas in the female, to the same quantity of female-determiner there is only one dose of male-determiner. But, since normally, in spite of the presence in individuals of either sex of determiners for both sexes, we get only the two classes male and female, we must say that (using the symbols M and F for our two sex-determiners) $2M > F$, whereas $F > M$.

When different races were crossed, abnormalities were produced. Goldschmidt was, in the first place, able to demonstrate that, whatever the degree of abnormality (and all degrees are possible), they fell into two classes, those which started their development as females but ended it as males, and those which started it as males and ended it as females. They thus have no kinship with the other main type of sexual abnormality known in insects, in which one half (or some definite section) of the body is of one sex, the other of the other. These latter animals are thus sex-mosaics in space, whereas Goldschmidt's are sex-mosaics in time. The term *gynandromorphs* should be restricted to the spatial type, the term *intersex*, or better *consecutive intersex*, being used for the other. The origin of gynandromorphs is to be sought in an abnormality of mitosis whereby an X chromosome is lost from one embryonic nucleus, whereas that of the intersex is to be looked for in the faulty balance of sex-factors.

It is only in certain crosses that intersexuality appears. An analysis of the families, together with the above-mentioned discovery of the transformation of sex during development in the intersexes, led to the following far-reaching conclusions. Broadly speaking, most of the Japanese races of the species possess sex-factors of high potency, the European races of low potency. Intersexes result (1) when a high-potency or "strong" M (male-determiner) is combined with a "weak" F—in which case the result is a *female intersex*, or one which is genetically female and starts its development as a female, but is later switched over to maleness; or (2) when two weak M's are combined with a strong F, in which case *male intersexes* are found.

Further, within each main group, the separate races may differ in regard to the strength of their sex-factors;

and this will be reflected in the different *degrees* of intersexuality resulting from different crosses.

These facts, and various interesting consequences of the facts, may be regarded as firmly established. It should be noted that there are one or two local races which have given curious results, which will have to be worked out in greater detail.

Goldschmidt's further argument is as follows. The expressions "2M - F" and "F > M" express only the conditions in the fertilised eggs before development has started. The further facts can be explained only if we suppose that, during development, in each cell of the body sex-controlling substances are produced at definite rates, and that these rates are proportional to the original quantities of the sex-factors. When, for example, a strong M and a weak F are present together in an egg, not only is the difference F - M abnormally small, but the rate of increase of F or of substances produced by it is lower, that of M higher, than usual. As a result, the two curves eventually intersect; and, of course, from this moment the individual, hitherto female, is switched over to the male type of development, and a female intersex is the result. The degree of abnormality is of course determined by the relative rates of F- and M-production, and the consequent earlier or later incidence of the intersection-point in the life-history.

If the intersection-point comes early enough, and the change to the "wrong" sex occurs before any chitinisation has taken place, sex-reversal will be apparently complete, and we shall get nothing but one sex from our cross. This does occur.

Let us suppose the sex-reversal is from female to male. Then, in the resultant all-male broods, half the individuals should be genetically females, and therefore be of chromosome-constitution XY instead of XX. If mated with normal females, therefore, they should give an abnormal sex-ratio (2XY = ♀♀ : 1XX = ♂ : 1YY —dies), as was pointed out in general terms by Morgan and by the reviewer some time ago. Similar sex-reversal followed by abnormal sex-ratio in the next generation has since been shown to occur by two independent workers in the frog, and now Goldschmidt has rung the changes upon it in Lymantria and has shown that in every case the results fit with expectation. Thus the final *somatic sex* may be the opposite of the original *zygotic sex*.

But we can go even further than that. The reversal (total or partial) of the original sex may be due either to genetic or to other factors. In Goldschmidt's moths the reversal is due to genetic causes—the fertilised egg contained inevitably within itself the seeds of its eventual change of sex, in the form of a quantitative disharmony of the sex-determining factors.

But sex may be upset by outer agencies: by hormones, in the case of vertebrates, whether the experiment be of Nature's (as in the Free-martin, the female intersex of cattle, owing its abnormality to the male hormones of its own twin brother), or of man's (as in the remarkable castration and grafting experiments of Steinach, Sand, Moore, Lipschütz, Goodale, and others); by parasites, as in crabs and insects; or by interference with the gametes, as in the increased number of males produced in frogs (Hertwig and his pupils) or trout (Mrsic) by over-ripeness of the ova.

The earlier rigid belief that sex-determination was entirely a matter of the chromosome-constitution must therefore be modified. Sex, in all higher animals and in some plants, is *normally* determined by the chromosomes, but (as might have been foreseen) the normal agency can in certain circumstances be overridden.

It is clear that, with the point of view arising from these facts, much that is both new and important has been gained. In the first place, we have the confirmation of the idea, which had become established as a result of the work on Drosophila, especially by Bridges, that sex-determination was an affair of balance between genes contained in the sex-chromosomes and other genes.

Bridges, by the utilisation of triploid strains, showed that in the fly, while the female-determiner was mainly lodged in the X (since here the female is XX, the male XY), male-determination was not an affair of one but of several factors, a disproportionate amount of influence being entrusted to that or those in the diminutive 4th chromosome. Two X's in the presence of three sets of autosomes gave intersexes: if only two instead of three of the 4th chromosomes were present, the intersexes were of more female type. We do not profess to understand Goldschmidt's comments (p. 99):—". . . . instead of speaking of the different quantities of a sex factor he [Bridges] prefers to speak of a more or less greater number of factors. Logically as well as physiologically this is naturally the same."

Although Goldschmidt has shown that his "F" substance is largely due to factors lodged in the Y chromosome, yet it may be confidently predicted that numerous "sex-modifiers" will be discovered in the autosomes.

Our second principle is concerned with development. Goldschmidt's idea of different rates of production of substances in the embryo is in itself very fruitful, while if his correlation of the rate of production of the substance with the amount of some initial ferment contained in the gene, and this amount with the "potency" of an allelomorph in a multiple series,—if this is substantiated, we acquire a new outlook into the relation between Mendelian genes and their mode of action in development.

That a correlation of some sort does exist between rate of developmental processes and nature of gene appears to be established; but whether there exists the exact chain of events imagined by Goldschmidt is a matter for further verification.

How valuable is the conception of rate of production of substances in ontogeny is seen by the rapid application which it has found in other fields. Crew has applied this idea to the explanation of various puzzling abnormalities of the reproductive organs to be found in mammals, and by so doing has removed them from the lumber-room where they lay labelled with the meaningless title of "pseudo-hermaphroditism" to a place in a coherent biological scheme. It appears more than probable that the determining factor in Amphibian metamorphosis, with all its curious variations from species to species, is simply the relative rate of thyroid growth. It will assuredly prove that the same concept will be of prime importance as regards the other endocrine glands in all their functions of growth-regulation and of initiating new phases such as puberty. In brief, the ideas of physical chemistry are thus being introduced into embryology, and dynamic ways of thinking substituted for static.

So much for the important positive results, both of fact and theory, which flow from Goldschmidt's work. It remains to criticise some of his details.

We think it right in the first place to emphasise the fact that the well-known curves illustrating the physiology of intersex production (p. 95) are quite hypothetical in their details—a fact not sufficiently brought out in the text. They could be drawn in a considerable number of quite other ways and still satisfy the facts. In particular, this applies to the representation of the curve for production of "female" substance as rising to a maximum and then sinking again. This is of great theoretical importance if really true; but no adequate discussion is given of the reasons for the adoption of this particular curve, nor for the rejection of, *e.g.*, a curve which continued to rise throughout life.

The same, *mutatis mutandis*, is true of various other of the curves presented later for other organisms—although here their hypothetical nature is made clearer. We think that in many cases it would have been equally easy to employ the idea of alteration in susceptibility of tissues to a constant stimulus (as exemplified, *e.g.* in the alteration in susceptibility of Anuran limbs to thyroid at metamorphosis) instead of that of alteration in the amount of morphogenetic substance (intensity of stimulus).

We note the absence of reference to Haldane's interesting work (in reality a corollary of Goldschmidt's own principles) that when one sex is reduced in numbers or abnormal in structure as a result of a varietal or specific cross, it is—not always the male or always the female, but—always the heterogametic; and also wonder why play is not made (pp. 222-224) with the idea that sex-linked semi-lethal factors account for the well-known differential elimination of males before and soon after birth in man and other mammals—an idea which at least gives full formal explanation of otherwise incomprehensible facts.

In his discussion of human sexual abnormalities (p. 243) the author has only been thinking in terms of his previous Lymantria scheme, which will give greater or lesser sex-transformation as a result of faulty balance of sex-genes: Crew's recent papers on goat and pig intersexuality suggest another and simpler explanation, in the idea of abnormally slow production of the male hormone, but without any switch-over from one sex to the other. No reference is made to the classical work of Pézard on birds, in which the effect of the gonad hormones upon growth-rate of sexual characters is so ably analysed.

These, however, are matters of comparatively minor moment. The main thesis of the book stands, and is of great value. In addition, various subsidiary topics are discussed with great lucidity. We especially commend the section on secondary sexual characters. The treatment is not new, but so clear and incisive that after reading it there should be no excuse for the not uncommon misconception that the inheritance of such characters throws any light upon or is in any way correlated with the inheritance of sex itself, save only that once sex is determined, it controls the *expression* of one or the other set of secondary characters.

The well-known difference between the physiology of sex-determination in insects and vertebrates—in the former independent of all gonadial influence, in the latter put under this influence from a very early period of ontogeny—the author correlates with the general shortness of life in insects as against its greater length in the higher group. This is an extremely suggestive idea; it will be interesting to see whether subsequent research upon the connexion of gonad and sexual characters in other invertebrates will bear it out. Finally, after the mass of nonsense and vague theorising that has been written on the sex-ratio, we commend his chapter on the subject as an admirable tonic.

It has seemed worth while to go into some detail regarding the thesis and scope of the book, in spite of its having been first published in German three years ago, since here for the first time are English readers provided with a translation (which, since Goldschmidt has incorporated recent work, is also a second edition). The book is intended for medical men and others, such as lawyers or sociologists, who may have occasion to study the problems of sex, as well as for the professional

biologist, and it is a fact, however unfortunate, that the great majority will not read a foreign language unless they must. The translation is direct and adequate, and reads smoothly, although a few Germanisms might be got rid of in a second edition.

Work on the problems of sex is proceeding so rapidly that Doncaster's and Morgan's books on the subject, although not ten years old, are quite out-of-date. We have no hesitation in recommending Goldschmidt's work as the best existing introduction to the subject, and tendering our thanks to Prof. Dakin for his translation. JULIAN S. HUXLEY.

Chemistry of Urea and Resins.

(1) *The Chemistry of Urea: The Theory of its Constitution, and of the Origin and Mode of its Formation in Living Organisms.* By Prof. Emil A. Werner. (Monographs on Biochemistry.) Pp. xii+212. (London: Longmans, Green and Co., 1923.) 14s. net.

(2) *Synthetic Resins and their Plastics.* By Carelton Ellis. Pp. 514. (New York: The Chemical Catalog Co. Inc., 1923.) 6 dollars.

(1) THE monograph on urea differs somewhat in scope from others of this series of which it forms a part, inasmuch as it deals almost exclusively with one compound. Its importance, however, in animal and vegetable life is unquestioned, and no one will feel that a whole volume devoted to this topic is an unnecessary addition to biochemical literature. The subject-matter is divided into two sections: the first treats of the synthesis and constitution of urea; the second with its origin and occurrence in Nature.

There is no one more competent to write on urea than the author, who for many years past has attempted to unravel its structure. A considerable portion of the first section is concerned with this problem, and it must be confessed that Prof. Werner has made out a strong case for the tautomeric formula

$$\mathrm{HN:C}\begin{cases}\mathrm{NH_2}\\ \mathrm{OH}\end{cases} \rightleftarrows \mathrm{HN:C}\begin{cases}\mathrm{NH_3}\\ |\\ \mathrm{O}\end{cases}$$

There is no doubt that the majority of changes which urea undergoes with different reagents and by heating, such as the formation of biuret, and the conversion of ammonium cyanate into urea, which is represented thus:

$$\mathrm{H_4N.O.CN} \leftrightarrows \begin{matrix}\mathrm{NH_3}\\ +\\ \mathrm{H.O.CN}\end{matrix} \rightleftarrows \mathrm{HN:C:O} \rightleftarrows \mathrm{HN:C}\begin{cases}\mathrm{NH_3}\\ |\\ \mathrm{O}\end{cases}$$

may be equally well explained by the new formula. Moreover, the formation of cyanuric acid and the action of alkalis receive a much simpler interpretation in this way.

(2) As a rule, an organic chemist, when confronted in the course of an investigation with a resinous product, is discouraged from examining it further. It is an amorphous, intractable material which generally defies crystallisation and, consequently, the only satisfactory means of purification. It is therefore consigned to the scrap heap. The technical chemist, on the other hand, whose business it is to manufacture varnishes and composite materials, such as printing-inks, paper and cloth size, linoleum, etc., far from despising such products, is able to utilise many so-called synthetic resins on a very considerable scale. The volume under review gives a very comprehensive account not only of the production and use of synthetic resins; but also a detailed description of the machinery used in their application. He tells us that "the diminishing supply of natural resins, or *gums*, as the trade prefers to call them, has been viewed with apprehension during past years by varnish manufacturers and other large consumers of such products."

It appears that the introduction of phenol-formaldehyde and cumarone resins has opened up a new field for the synthetic organic chemist. There is a remarkable variety of substances now employed and derived from such products as glycerin and phthalic acid, vinyl polymerisation products, urea and thiourea derivatives and sulphur phenol resins. The author advises the chemist to scrutinise carefully every new resin he may obtain and record its formation. Here is a new and interesting field of operations, and instead of feeling thwarted in his aim, the organic chemist may in future turn what he formerly regarded as a failure into a possibly lucrative success. J. B. C.

Micrography as a Fine Art.

Botanical Pen-Portraits. By Prof. J. W. Moll and Dr H. H. Janssonius. Pp. viii+472. (The Hague: Martinus Nijhoff, 1923.) 30 guilders.

IT was not until about the middle of the nineteenth century that descriptions of microscopical characters were introduced into treatises concerned with the identification of drugs. There are now several books primarily designed for students of pharmacy, but occasionally referred to by botanists who endeavour to demonstrate to their students that even a knowledge of plant histology may have its economic value. The volume by Prof. Moll and his junior collaborator aims at giving greater precision to the description of vegetable drugs and therefore greater accuracy in their identification.

Prof. Moll has devoted himself during the last twenty

years to a subject which demands no little concentration of effort and an enthusiasm that is proof against the dullness of tedious routine; he has devised a method of scientific description which he believes to be an advance upon all previous systems. The technical value of this method can only be thoroughly tested by specialists, but a mere botanist can at least appreciate the soundness of the underlying principles and the meticulous attention to details. The author is to be congratulated on the successful completion of a labour of love which is a contribution of great value to the pharmacologist and to all botanists whose aim is to acquire an orderly and thoroughly sound method of describing plant structures.

An adequate description of a plant must take account not only of the characters in which it differs from allied types, but also of those which it shares with other plants. Pen-portraits aim at furnishing a summation of characters, the replacement of sketches of habit by clear descriptions based on a definite scheme which is given in full and constitutes a very important feature of the book. They do not rely upon detailed anatomical drawings to supplement imperfect descriptions: a pen-portrait, if thoroughly made, is self-sufficient and at most needs only a well-labelled diagrammatic representation of the plant organ under consideration; it brings into the description "as much as possible of what is now generally considered as belonging to the domain of drawings and plastic models, in other words, it tends to make pictures more and more superfluous." The diagrammatic illustrations are exceedingly clear, and of a kind which might with advantage be adopted as a model by authors of botanical text-books.

The value of Prof. Moll's method was demonstrated by the junior author, Dr. Janssonius, in his book, published in 1906, on the micrography of Javan trees: an extension of the same method to timber trees of other regions would be a great boon to botanists, especially to such as are interested in the identification of fossil angiospermous woods.

The preface, which is much more than a preface in the ordinary sense, gives a clear account of the history of descriptive botany, with special reference to microscopical features, and emphasises the importance of a more definite employment of the Linnean method in micrography. Prof. Moll considers that the principal feature of the Linnean method is its conformity to a sequence fixed beforehand; if it is rigorously followed, completeness is achieved and nothing is omitted by chance. A high standard is set, and the "guiding schemes," if the student has sufficient faith and patience to adopt them, supply the means of constructing pen-portraits according to the admirable patterns contained in this great work. Most of the volume is devoted to descriptions of drugs arranged in alphabetical order—Amylum, Cortex, Flores, Folia, Fructus, etc.—and a full bibliography is added. In illustration of the method, the headings of the section dealing with Cortex Cinnamomi may be given: macroscopic characters; anatomical characters, followed by a list of references; epidermis, including measurements of cells; cortex, cork, phellogen, phelloderm; primary cortex; endodermis; stele, including detailed description and cell-contents of the tissues; micrography of the powder, bast fibres and other cells, crystals, starch grains, etc. A word of praise is due to the publishers for the printing and style of the book, and to the authors for their decision to present their work in well-written English. A. C. Seward.

Our Bookshelf.

Text-book of Agricultural Bacteriology. By Dr. F. Löhnis and Prof. E. B. Fred. (Agricultural and Biological Publications.) Pp. ix + 283 + 10 plates. (New York and London: McGraw-Hill Book Co. Inc., 1923.) 15*s.*

Dr. Löhnis' "Vorlesung über landwirtschaftlicher Bakteriologie" has for so long been regarded as an essential text-book, that students of agricultural bacteriology will especially welcome the excellent English edition of this work which the author has produced in collaboration with Prof. E. B. Fred.

The authors devote the first portion of their work to a description of the characteristics and general activities of micro-organisms. This part of the book contains useful chapters in which the general methods used in studying the organisms are discussed. The second half of the book is devoted to the special fields of bacteriology that touch upon the problems of agricultural research and practice. There are chapters on the bacteriology of silage, hay, and other food materials, on milk, butter, and cheese, on the methods of sewage disposal, on the changes involved in the making of farmyard manure and on the problems of soil biology. In these chapters the authors deal with their subjects with remarkable clearness. The very different problems that arise in these fields of work make it very difficult to connect them as though they formed a single branch of applied science. It seems that the sequence of thought would have been better preserved in this portion of the book if the bacteriology of soil had been considered before that of dairy products, because, in the former subject, the problems involved so completely cover the field of microbiology, that the authors have already been obliged to refer to the chief groups of soil bacteria to illustrate the activities of bacteria in general. In dealing with the bacteriology of soil and of dairy products, the authors discuss some of the special methods used in these fields of work. In a later edition, the description of special methods might well be given in greater detail. At present, lack of standardisation in technique greatly hinders work with bacteria, and this is especially the case with soil and dairy bacteriology. A detailed description of the best

methods, given in such a well-known text-book, would greatly assist the adoption of a uniform technique.

In the portion of the book devoted to soil bacteria, the activities of protozoa and other micro-organisms are mentioned, but greater emphasis should have been given to the close interrelation that exists between bacteria and other organisms in the soil. The close connexion found to exist in field soil between the rapidly changing numbers of bacteria and active amœbæ illustrates the fact that the bacteria must be considered as a part of the complex population of the soil. H. G. THORNTON.

Mine Examination Questions and Answers. Compiled from Examinations for Positions of Mine Inspector, Mine Foreman, Assistant Foreman, Fireboss, Hoisting Engineer, Safety Inspector and Shotfirer. By Prof. J. T. Beard. Part 1. Pp. viii + 258. Part 2. Pp. vi + 259–546. Part 3. Pp. vi + 547–872. (New York and London: McGraw-Hill Book Co. Inc., 1923.) 3 parts, 37*s.* 6*d.*

THE object of the work under notice is, as stated by the author in his preface, that of "enabling candidates to pass successful examinations for positions of responsibility in coal mining," and it consists of a set of answers to no less than 2975 questions, set in examinations in the various coal-mining states of the United States of America and in Canada for various grades of colliery officials. Opinions will certainly differ as to whether this is the best way of qualifying a man for the duties that he will have to perform after he has passed such examination; it may readily be granted that a man, gifted with an exceptional memory, might get off by rote the whole of the answers to the questions given in these three volumes and would thus with ordinary luck pass successfully any of the examinations referred to, but it is also very certain that this fact would not qualify him to hold a position as a responsible underground official. The educational value of such a book is therefore very questionable. At the same time the work has been well done. Prof. Beard has been the Principal of the School of Mines, International Correspondence Schools, Scranton, Pa., Secretary to the State Board of Mining Examiners, Iowa, and has held many other positions that qualify him thoroughly for the work that he has undertaken, and his book may be used with every confidence in its accuracy. It must, however, be borne in mind that coal mining methods, legislation, and nomenclature are so different in the United States from what they are in Great Britain that many of the answers given would prove seriously misleading to British candidates for similar positions in the latter country.

The Properties of Matter. By Prof. Basil C. McEwen. Pp. vi + 316. (London: Longmans, Green and Co., 1923.) 10*s.* 6*d.* net.

As a text-book, this work differs from its predecessors in the order of treatment of the subjects. Commencing with the First Law of Thermodynamics and the more general Principle of the Conservation of Energy, a logical sequence leads to the study of the kinetic theory of matter, which is most easily treated in connexion with the gaseous state. The continuity of the gaseous and liquid states supplies the natural transition to a detailed study of liquids, and solids are dealt with last of all. The reviewer can recommend this order from his own experience in lecturing to university students, and is of the opinion that the first half of Prof. McEwen's book reaches a high standard of excellence. Some parts of the latter half are not quite so satisfactory. The chapter on capillarity seems somewhat elementary and does not contain many references to modern work. The distinction between surface tension and surface energy is not well brought out. The chapter on solids is very short, and should be greatly expanded when a new edition is called for. We hope the author will then include an account of the crystalline structure of solids as revealed by X-ray analysis. H. S. A.

Medical Climatology of England and Wales. By Dr. E. Hawkins. Pp. xiv + 302 + 149 charts. (London: H. K. Lewis and Co., Ltd., 1923.) 25*s.* net.

EVERY practitioner of medicine is frequently required to recommend a climate suitable for convalescence or for a chronic disease; few doctors can acquire from experience the geographical and meteorological knowledge to enable them to give adequate consideration to this important detail of treatment. Dr. Edgar Hawkins provides a volume on the subject, based on his own experience and the information derived from numerous meteorological publications. The main arrangement of the book is geographical, therapeutic indications following the descriptions of the geology and climate of various districts and towns. There is also a separate chapter on therapeutics of the English climate, in which the classification is based on diseases. In one appendix the health resorts are tabulated according to seasonal suitability, and in the other the waters of the various Spas are described.

. In spite of the complexity of the subject, information with regard to locality or disease can readily be found, and reference is facilitated by the inclusion of a large number of meteorological charts and the addition of a well-prepared index. The book will be of considerable value to physicians and others interested in medical climatology.

The Elements of Co-ordinate Geometry. By S. L. Loney. Part 2: *Trilinear Co-ordinates, etc.* Pp. viii + 228. (London: Macmillan and Co., Ltd., 1923.) 6*s.*

THIS part of Prof. Loney's "Co-ordinate Geometry" contains, in order, chapters on cross-ratio geometry, trilinear and areal co-ordinates, tangential equations, reciprocation, projection, and invariants of conics. Methods of teaching geometry have advanced considerably in the last twenty years, and the arrangement adopted by Prof. Loney would scarcely be accepted as the natural one now. Trilinear and areal co-ordinates are here introduced from the purely metrical point of view. Now it would be more customary to read the chapters on projection and reciprocation first and then to treat trilinears and areals as particular cases of homogeneous co-ordinates.

Coming from an experienced teacher of mathematics, the book gives all necessary assistance to a student reading its subject-matter for the first time in the order treated. Abundant examples are given, but those on homogeneous co-ordinates include a greater proportion of metrical questions than a present-day teacher would endorse (*e.g.* pp. 85-87, Nos. 1, 2, 6, 7, 16, 17, 20, 22, 23, 24).

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

The Gorilla's Foot.

WITH regard to Mr. Akeley's cast of a gorilla foot discussed in NATURE of November 24, p. 758, I note that Sir Ray Lankester did not wait until he had seen the cast which we sent to the British Museum (Natural History) but has again made the following charges :—(1) The picture of the cast of the foot in Mr. Akeley's book "In Brightest Africa," p. 242, gave a misleading or distorted view of the cast and was in effect an example of bad photography. (2) The gorilla foot as represented by the cast differed in appearance from all previous pictures of and statements about the gorilla's foot and was misleading, chiefly because it did not show the great toe in a divergent position; it also differed in appearance from the photograph of another gorilla's foot figured by Akeley in the same book (p. 231), in which the great toe was shown in the flexed and abducted position. (3) Therefore Akeley had himself supplied the refutation of his claim that his gorilla's foot was different from any other yet discovered. (4) That it is "highly improbable" that Akeley's photograph of the cast "correctly represents the foot of a normal species or variety of gorilla."

As to (1), I have already stated (NATURE, November 24) that the photograph published in Mr. Akeley's book gave a "very fair" view of the cast in question, and after a careful re-examination of the facts I will add nothing to that statement except that Mr. Akeley has a deservedly high reputation based upon many years of experience both in photographing and in making anatomical casts, and needs no warning from any one as to the precautions to be observed in such work.

As to (2), neither Mr. Akeley nor I ever asserted that the cast in question showed the hallux in the position that it probably assumed when the animal's weight rested upon it. I quoted Mr. Akeley's statement that the cast was taken in the relaxed condition of the foot after *rigor mortis* had passed away, and I also noted that the hallux could no doubt be more or less abducted. The cast was made within twenty-four hours after death, in a cool, moist climate. The foot was cut off from the leg, the muscles and ligaments being relaxed, and was placed in a hollow in the ground with the sole facing upward. The foot and its digits were not posed but were allowed to assume the relaxed position. After being lightly soaped a thin coating of plaster was then applied and allowed to set, in order to prevent distortion by the weight of the plaster. No other outside pressure was exerted in any direction when the plaster was poured around. The whole operation was conducted with exceptional care to avoid distortion.

The outstanding feature of Mr. Akeley's cast is that it shows that in the relaxed condition the hallux assumed a position of lesser divergence, so that it was more nearly in line with the other digits. In this connexion it is pertinent to state that Dr. D. J. Morton is now studying the anatomy of the foot of another one of Mr. Akeley's adult gorillas, and finds that the arrangements of the internal cuneiform and first metatarsal bones are such that it is possible for the hallux to be drawn into the position shown in Mr. Akeley's cast. Dr. Morton has also found that in Mr. Akeley's, as well as in other adult specimens, the distal ends of the metatarsals of all the digits are twisted upon the shafts at different degrees in such a way as to make the volar surfaces face more directly downward, whereas in infant gorillas the volar surface of the hallux is tilted toward that of the other digits, this arrangement being still more pronounced in the chimpanzee. After extensive comparison, Morton concludes that the infant gorilla foot retains more of the primitive arboreal characteristics, while the adult gorilla foot shows numerous man-like adaptations not found in the chimpanzee.

As to (3), Mr. Akeley never claimed that his gorilla's feet were different from all others previously described. Such may yet prove to be the case in regard to the detailed proportions and minor characters of the foot, but it has not yet been asserted by either Mr. Akeley or myself.

As to (4), the original foot from which the cast was made has not yet been compared minutely with the other gorilla feet collected in the same general region, but after a preliminary comparison there seems no reason to brand the individual as representing an "abnormal species or variety."

In brief, Mr. Akeley's cast can be misleading only to those who read into it more than was claimed for it, or who do not realise that a gorilla's hallux may assume a position other than that figured in the previous literature of the subject. A carefully made cast of this kind is of greater scientific value than any photograph of the same object, because it represents the object in the round and without photographic distortion. A good cast, such as this unquestionably is, gives indisputable evidence of fact.

In conclusion, Sir Ray Lankester's statements in his book, "Great and Small Things," about the significance of the differences between human and anthropoid feet, suggest that he is one of several eminent persons (including Mr. H. G. Wells) who do not see that the human foot is an anatomical palimpsest, in which the later record of a long terrestrial life is so deeply impressed that it has largely obscured the underlying older record of a previous arboreal stage with a divergent hallux. This is not a "theory" but a well-founded inference from the many facts that are now being examined by Sir Arthur Keith, Dr. Morton, and others.

WILLIAM K. GREGORY.
American Museum of Natural History,
New York, December 7.

Psycho-Analysis and Anthropology.

REFERRING to the letters in NATURE from Dr. Malinowski (November 3) and Prof. Elliot Smith (November 24) on this subject, I should like to make three remarks.

(1) While agreeing with all that Prof. Elliot Smith says as to "Totem and Taboo," and that Freud failed to acquaint himself with the essential facts and associations of which he writes, this is by no means the case with all of his disciples, while even in "Totem and Taboo" there is stress laid on the quality of ambivalence in savage belief and custom, which, if I judge rightly, had not previously been sufficiently appreciated by anthropologists. It may be that Prof. Elliot Smith has recognised this in his article in the *Monist*, which I have not had the opportunity of reading.

(2) I rather doubt whether time will bear out Prof. Elliot Smith's contempt for typical symbols. Type dreams—that is, identical dreams having the same meaning attributed to them—certainly occur among peoples genetically and culturally remote. Thus, to take an example, quite superficial reading, and the kindness of friends in supplying references, indicates

that the tooth-losing dream occurs in Europe and among Nagas, Malays, and Chinese, also Ashanti, and that in each case it is taken to mean the death of a near relative (Ashanti, loss of near friend). Moreover, this meaning fits well with the individual significance commonly recognised by analysts, namely, the fear of castration.

(3) The question of "Universal Symbolism" is of course the crux of the whole matter. Are the findings of analysis for the individual applicable to the social unit to which he belongs; and if so, do they also apply to other groups which may be genetically remote?

Those interested should shortly have the opportunity of hearing the problem examined from the psycho-analytic point of view, for Dr. Ernest Jones has consented to read a paper upon this subject before the Royal Anthropological Institute on Tuesday, February 19. Tickets of admission will willingly be sent to non-members of the Institute interested in the subject, who should apply to the Assistant Secretary, Royal Anthropological Institute, 50 Great Russell Street, W.C.1.

C. G. Seligman.

Malaria and *Anopheles funestus* in Mauritius.

Early in 1922 I was asked by the Secretary of State for the Colonies to undertake an Anopheline and anti-malaria survey in the island of Mauritius. I accepted this mission, and had the pleasure of devoting ten months of intensive investigation to a survey of unusual interest.

Prior to my visit to Mauritius, a somewhat similar survey had been made in 1908 by Sir Ronald Ross, Major Fowler, and Mr. d'Emmerez de Charmoy. The valuable work they accomplished and the many interesting observations made by them are recorded in Ross's report entitled "Prevention of Malaria in Mauritius" (London, Waterlow and Sons, 1908).

In the course of their work, Ross, Fowler, and d'Emmerez de Charmoy made an extensive survey of the mosquitoes of Mauritius, which resulted in the collection of the following species:

Old Nomenclature.

1. *Myzorhynchus mauritianus.* Daruty de Grandpré & d'Emmerez de Charmoy.
2. *Myzomyia (Pyretophorus) costalis.* Theobald.
3. *Nyssorhynchus maculipalpis.* Giles.
4. *Scutomyia notoscripta.* Walker.
5. *Stegomyia fasciata.* Fabricius.
6. *Culex fatigans.* Weidemann.
7. *Culex tigripes.* Daruty de Grandpré & d'Emmerez de Charmoy.
8.[1] *Culex annuliorius.* ?
9. *Culex arboricolis.* d'Emmerez de Charmoy.
10. *Culex ronaldi.* d'Emmerez de Charmoy.
11. *Culex fowleri.* d'Emmerez de Charmoy.

Modern Nomenclature.

1. *Anopheles mauritianus.* Daruty de Grandpré & d'Emmerez de Charmoy. Very common.
2. *Anopheles costalis.* Theobald. Very common.
3. *Anopheles maculipalpis.* Giles. Very rare.
4. *Aēdes albopictus.* Skuse.
5. *Aēdes argenteus.* Poiret.
6. *Culex fatigans.* Fabricius.
7. *Lutzia tigripes.* Daruty de Grandpré & d'Emmerez de Charmoy.
8.[1] *Culex annuliorius.* ?
9. *Orthopodomyia arboricolis.* d'Emmerez de Charmoy.
10. *Culex sitiens.* Weidemann.
11. *Aēdes nigerensis.* Theobald.

[1] *Note.—Culex annuliorius* should not be listed among the mosquitoes of Mauritius, as the record is probably due to an error in identification.

It will be seen from this list that three species of Anophelinæ were found, and I have added the remarks made by these investigators relating to the prevalence of the Anopheline species.

By experimental work in Mauritius, Ross was able to prove that of the three Anophelines, *A. costalis* was easily infected with malaria and could be regarded as the chief vector; that *A. mauritianus* apparently could not be experimentally infected with malaria, and by much additional evidence could be regarded as incapable of malaria transmission; while, owing to the great rarity of *A. maculipalpis*, which these investigators state was then the case, there was no opportunity of obtaining *A. maculipalpis* in numbers sufficient for experimental work. Its presence in Mauritius was therefore considered of no practical importance at the time.

Based on these discoveries, Ross indicated the plan that should be adopted for the institution of an anti-malaria campaign in Mauritius. Unfortunately, his recommendations were not thoroughly carried out, and although much useful work was done by the canalisation of streams and the abolition of swamps in many parts of the island, the success of the campaign was vitiated by the neglect of equally important Anopheline breeding-places, and in many cases by allowing the completed anti-anopheline works to revert to natural conditions.

Consequently, fourteen years afterwards malaria in Mauritius was as bad as ever—a fact which, together with the totally insanitary state of the island, led the Governor, Sir Hesketh Bell, to decide to ask the Colonial Office to appoint an expert in tropical hygiene to visit the island and indicate the necessary measures for the correction of the many serious defects.

The Secretary of State for the Colonies called upon Dr. Andrew Balfour to undertake this mission, and Dr. Balfour left for Mauritius in February 1921. The utterly insanitary state of the island, and the very large number of separate problems with which Balfour had to contend, are fully set out in his comprehensive report, entitled "Report on the Medical and Sanitary Matters in Mauritius, 1921," published by the Colonial Office.

With regard to malaria in the island, Balfour speedily saw that, for renewed effort against the Anophelinæ, it was essential to know more of the bionomics of *Anopheles costalis*, the species then thought to be the only species responsible for the intensely malarious condition of Mauritius. His view was that it was highly important to know whether the species did or did not hibernate during the winter months, at least at the higher altitudes of the island, so that future work might take into account this most important fact.

On his return to England, Balfour recommended that investigations to determine the bionomics of *A. costalis* should be undertaken. I therefore left England for Mauritius early in 1922 to carry out this work.

For the first four months after my arrival in Mauritius (then the winter months), my staff and I gave undivided attention to the work of determining whether *Anopheles costalis* exhibited hibernation; and we were successful in showing that hibernation did not occur either at the coast or inland—a matter that is fully dealt with in my report to be published shortly by the Colonial Office.

During the work on *A. costalis*, much to my surprise I discovered that, in spite of what Ross had said in 1908, *Anopheles maculipalpis* was now to be found in very large numbers all round the island and up to an altitude of 1200 ft.

Later, with more time to devote to further studies

after *A. costalis* and the hibernation problem had been settled, my assistant and I while searching a marsh near Port Louis were astonished to find a larva of *A. funestus*. Further search in this marsh demonstrated that *A. funestus* was here in large numbers. The fact that *A. funestus* had not been recorded from Mauritius before, in spite of the work of the previous investigators, coupled with the proximity of the marsh to Port Louis—where all ships enter Mauritius—led me to assume that the species had only recently been imported. I immediately approached the Officer Administering the Government for authority and funds to abolish this marsh; and by the copious use of paraffin castor-oil mixture, while hundreds of men tore up the weeds, by drainage and filling-in operations, within a few days the marsh was changed into dry land.

Control of all the nearby waters—fortunately few—was instituted, and no larva appeared in these waters. A few days later, while I was in conversation with one of the chief moustiquiers (mosquito searchers)—an Indian who had been trained by Ross and Fowler—this man told me that he thought he remembered having seen similar larvæ while Ross was in the island, at Schonfeld Marsh, Riviere du Rempart in the north.

I questioned him further, pointing out that it was difficult to remember the appearance of larvæ after the lapse of 15 years; but he seemed so certain that I despatched him to Schonfeld to search. Schonfeld Marsh is rather inaccessible, some 15 miles from the marsh at Port Louis, and as the man had to go on foot it was two days later before he returned.

When he got back, however, he brought with him six larvæ of *A. funestus*. My assistant and I at once left for Schonfeld Marsh in my motor-car, taking the man with us, and after searching for two hours in this extensive marsh, I discovered a larva of *A. funestus* there for myself.

On my return to Port Louis, I issued instructions that all moustiquiers should divide up and proceed to all parts of the island and search only for *A. funestus*. Two weeks later, *A. funestus* had been reported from practically every district of Mauritius, but the numbers found were surprisingly few.

I then decided personally to undertake the study of the bionomics of the species, and I at last found—as I have fully described in my report—that *A. funestus* existed in Mauritius in prodigious numbers, in some localities actually outnumbering *A. costalis*. The failure to discover the larvæ in numbers before was due to the fact that the vibrations transmitted through the earth by the tread of the searchers warn the larvæ of danger, and they all dart to the roots of the vegetation, to which they cling, *or even climb a few inches up the damp surfaces of the leaves* which dip into the water. Once this fact had been discovered, thousands of *A. funestus* larvæ could always be had in suitable breeding-places.

I undertook experiments in malaria transmission by *A. funestus* and *A. maculipalpis* in the island, and found that the former species could very easily be infected, and that *A. maculipalpis* could also be infected without much difficulty. Consequently, instead of *A. costalis* being the only vector of malaria in Mauritius, there are in reality three vectors: *A. costalis*, *A. funestus*, and *A. maculipalpis*.

Now, there are two theories to account for the malaria in Mauritius:

(1) That *A. costalis* (and *A. funestus* and *A. maculipalpis* ?) have existed in Mauritius for centuries, and that it was only the importation of large numbers of Indians to work in the sugar-cane industry, bringing with them in their blood the parasites of malaria, that caused the extensive infection of the local anophelines.

(2) That prior to 1865, when the first considerable outbreak of malaria (?) occurred, no anopheline vector existed in the island, and that it was only by accidental importation of *A. costalis* (*A. funestus* and *A. maculipalpis*?) then that Mauritius became malarious.

Personally I am inclined to favour the first theory, but the following experience shows how impossible it is to be dogmatic.

Towards the end of my work in Mauritius, hearing that the sister island of Rodrigues was free of malaria, I obtained sanction from the Officer Administering the Government to proceed to Rodrigues in order to investigate this report.

The island is so small that it was possible, with the assistance of three skilled helpers, to search all the streams, marshes, and pools. No Anopheles were to be found, and no case of malaria acquired in Rodrigues existed, although on the other hand I was able to find persons with all three species of the malaria plasmodia in their blood, which they had acquired by former residence in Mauritius.

The island of Rodrigues lies 365 miles to the east of Mauritius, and is visited regularly, though only every 3-4 months, by the Government supply steamer from Mauritius. On this ship, which is berthed in Port Louis, *A. costalis* was found even during my voyage, and it seems obvious that the only thing that accounts for the fact that Anophelines have not been introduced into Rodrigues is that the island is completely surrounded by an extensive and remarkable coral reef, running from 1½-6 miles seaward, which forces all vessels to anchor at least 1½ miles from shore. Moreover, a steady wind from the south almost invariably blows across the island from the shore across the anchorage.

In my report I have described these investigations at length, but I am in the meantime asking Sir Ronald Ross if he will be good enough to add any remarks he may care to make on what these investigations have shown. MALCOLM E. MACGREGOR.

Wellcome Field Laboratory, Wisley, Surrey
(Wellcome Bureau of Scientific Research).

THESE investigations appear to me to be both theoretically and practically important. The question is whether *A. funestus* entered Mauritius after my visit in 1908. Major C. E. P. Fowler and myself were in the island from November 20, 1907, until February 25, 1908, that is, during the summer. Of course, we could not make anything like a complete survey of the mosquitoes in that time, but we were given the assistance of Mr. D'Emmerez de Charmoy, the accomplished entomologist of the island and curator of the museum, and were also provided with ten "moustiquiers," that is, trained mosquito men. Our principal investigations were made close to the Clairfond Marsh at Phœnix—which was drained in 1908; but Major Fowler and Mr. D'Emmerez investigated much further afield than this. It is therefore most surprising that we did not once come across *A. funestus*. I remember that when I first found *A. costalis* in the island I expected to discover *A. funestus* pretty shortly, partly because we had found them in association in Sierra Leone (where indeed we had discovered and named *A. funestus*), and also because we heard that both mosquitoes abounded in the neighbouring island of Madagascar. It seemed surprising to me that only one of these Madagascar Anopheles had managed to drift into Mauritius. Moreover, we heard that it

was absent from the island of Réunion, where *A. costalis* was present. I understand that Mr. MacGregor found *A. funestus* in numbers during the period of summer when we were in the island; but, in addition to all this, it is most remarkable that Mr. D'Emmerez, who was appointed in charge of the antimalaria measures after we left, had not detected this mosquito during all these years. The most likely inference appears to me to be that *A. funestus* has been imported quite recently. I wonder whether it has also appeared in Réunion.

In my report I discussed the question whether malaria had been introduced into Mauritius and Réunion in 1866–7 (as was the case) by the introduction of large numbers of coolies from India, or by the introduction of *A. costalis*, and I preferred the latter theory. Against the coolie theory there was the fact that Indians had been pouring into both islands long before those years. I thought it more likely that *A. costalis* had been brought in some time previous to 1866, possibly by some ship. If therefore *A. funestus* has been a new introduction, this hypothesis of mine will be further supported. The entire absence of both species from Rodrigues is another confirmation. The most likely picture appears to me to be that all three islands were Anopheles-free up to 1865 or so, but that two of the islands have become infected since by shipping from Madagascar. I understand that both species are absent from India, but have not been following the recent literature.

It is very disappointing that all the antimalaria measures advised by me have been allowed to fall into abeyance in Mauritius, and I have long been convinced that anti-mosquito work will not be properly carried out in British dominions until stronger discipline is enforced. RONALD ROSS.

Methods of Chemical Reactions.

THE general scheme of a chemical transformation can be reproduced by the equation:

$$\left.\begin{aligned} &x_1 A_a B_b C_c \ldots + x_2 A_d B_e C_f \ldots + x_3 A_g B_h C_l \ldots + \\ = &y_1 A_m B_n C_p \ldots + y_2 A_q B_r C_s \ldots + y_3 A_z B_u C_w \ldots + \end{aligned}\right\} \text{I.}$$

A, B, C represent chemical elements or groups of elements, which are transferred as whole complexes from one side to the other of the chemical equation (*i.e.* NH_4, SO_4, NO_2, etc.). We shall call these groups of elements for short the *elementids* of a chemical equation; the chemical elements are thus the simplest elementids. It is evident that in determining the number of elementids of a chemical equation the minimum rule must be observed—that is, the elements must be brought together into groups, so that the number of these groups (elementids) shall be the smallest possible. The composition of these groups must fulfil one condition: that their number taken as a whole and for each formula individually should be the same on the right and on the left side of the chemical equation. In most cases the problem of determining the elementids is simplified by the fact that the number of elementids is the same as the number of elements.

a, b, c, d, etc., as usual in chemical equations, are numbers showing how many times a given element (or elementid) occurs in the composition of a chemical compound. Equation (1) contains molecules composed of all elements of a given chemical transformation; of course, the absence of some elements in the composition of a particular chemical molecule is expressed by making the corresponding multiplier (*i.e.*, a or b or c, etc.) equal to zero.

x_1, x_2, x_3, also y_1, y_2, y_3, etc., are the numerical coefficients to be determined by chemists using chemical equations.

To determine these coefficients algebraically, according to the rule requiring an equal number of elements on both sides of a chemical equation, we can write:

$$\begin{aligned} x_1 a + x_2 d + x_3 g + \ldots &= y_1 m + y_2 q + y_3 z + \ldots \\ x_1 b + x_2 e + x_3 h + \ldots &= y_1 n + y_2 r + y_3 u + \ldots \\ x_1 c + x_2 f + x_3 l + \ldots &= y_1 p + y_2 s + y_3 w + \ldots \end{aligned}$$

In calculating the numerical values of the coefficients x_1, y_1, x_2, y_2, etc., as required by stoichiometry, the following rules must be observed: first, all the coefficients must be whole and positive numbers; the coefficients must not have a common divisor. This last condition is satisfied by giving the smallest possible whole number to the coefficient of the molecule occurring the least number of times in a chemical reaction.

It follows from the series of equations that the number of elementids of a chemical equation corresponds to the number of separate equations serving to determine the necessary coefficients; and the number of heterogeneous molecules (separate substances) taking part in a chemical reaction corresponds to the number of unknown quantities. Hence:

In the simplest case the number of separate substances taking part in a chemical reaction will be greater by one unit than the number of elementids.

To illustrate this we shall give several chemical equations:

(*a*) *Two elements and three substances:* An example of the simplest reaction is the formation of water (two elements, H and O, and three substances, H_2, O_2, and H_2O).

(*b*) *Three elements or elementids and four substances:*

(1) $2C_2H_4O_2 + Zn = Zn(C_2H_3O_2)_2 + H_2$; the three elementids are Zn, H, and $C_2H_3O_2$.

(*c*) *Four elements and five substances:*

$$4S + 6NaOH = 2Na_2S + Na_2S_2O_3 + 3H_2O.$$

(*d*) *Five elements and six substances:*

$$2Sr(NO_3)_2 + 6NH_4Cl = 2SrCl_2 + 5N_2 + Cl_2 + 12H_2O.$$

(*e*) *Six elements and seven substances:*

$$K_2Cr_2O_7 + 6HI + 4H_2SO_4 = K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3I_2.$$

More complex chemical equations containing more than six elementids are comparatively rarely met with in chemistry.

We shall now investigate an example in which seven elements and eight substances take part in a reaction:

$$x_1 K_3Co(CN)_6 + x_2 H_2SO_4 = y_1 CoSO_4 + y_2 K_2SO_4 + y_3 (NH_4)_2SO_4 + y_4 CO + y_5 CO_2 + y_6 SO_3.$$

By solving the algebraical equations corresponding to this chemical reaction we get the following:

$$2K_3Co(CN)_6 + 24H_2SO_4 = 2CoSO_4 + 3K_2SO_4 + 6(NH_4)_2SO_4 + 11CO + CO_2 + 13SO_3.$$

This reaction is so complex, that even Prof. Treadwell, who did not know of the algebraical method of finding the coefficients, wrote the equation wrongly from the strictly stoichiometrical point of view. His rendering of it was as follows: [1]

$$2K_3Co(CN)_6 + 12H_2SO_4 + 12H_2O = 2CoSO_4 + 3K_2SO_4 + 11CO + CO_2 + 6(NH_4)_2SO_4 + SO_3.$$

[1] Treadwell, "Analytical Chemistry," vol. ii.

Here there are seven elements, but nine substances. One need not be a profound mathematician in order to understand that according to the scheme of a chemical reaction evolved by us, Treadwell's example just given contains, in the equation of reaction, substances the coefficients of which in certain limits can be arbitrarily changed. Such substances are: on one hand, H_2SO_4 and H_2O, on the other SO_3.

Thus, if we express the number of elementids by the letter L, the number of chemical substances taking part in the reaction by the letter M, we shall get for the simplest case of a chemical equation the expression:

$$M = L + 1.$$

We have looked through a number of chemical works and have found no exceptions to this rule. The seeming exceptions, carefully analysed, were found to be only complications, substantiating the rule announced. In the well-known "Analytical Chemistry" of Prof. Treadwell (vol. i.) out of 1240 reactions, 688 follow directly the rule announced. We shall show below that the seeming exceptions are only more complex cases.

Let us consider a first possible complication: it is evident that by addition of two or several chemical equations, we obtain a new chemical equation, but a more complex one; to find in this case the applicability of the simplest rule governing a simple chemical reaction, a special analysis is required.

Let us consider the case of double decomposition, which from a chemical point of view consists of two reactions: a reaction of combination and a reaction of decomposition. This complication affects adversely the immediate applicability of the rule announced. In this case the number of elementids increases, but the new elementids give algebraical equations resulting in the same solutions as those given by the number of equations demanded by the rule $L = M - 1$, so that to find the necessary coefficients it is sufficient to take only the algebraical equations according to our rule. To demonstrate this we will take an example:

$$x_1 AgNO_3 + x_2 H_2S = y_1 HNO_3 + y_2 Ag_2S.$$

Here there are the following equations: for Ag, $x_1 = 2y_2$, for NO_3 (elementid), $x_1 = y_1$, for H, $2x_2 = y_1$. These suffice already, for by taking $y_2 = 1$, we obtain $x_1 = 2$, $x_2 = 1$ and $y_1 = 2$. It is possible to make an equation for sulphur, $x_2 = y_2$, but this equation gives no new data and can only serve to control the preceding equations.

Here is another example [2] of a complex reaction:

$$8KClO_3 + 24HCl = 8KCl + 12H_2O + 9Cl_2 + 6ClO_2.$$

The corresponding simple reactions are:

$$KClO_3 + 6HCl = KCl + 3H_2O + 3Cl_2$$
$$5KClO_3 + 6HCl = 5KCl + 3H_2O + 6ClO_2.$$

Adding together the last two equations and dividing throughout by the factor 3 common to all the coefficients, we obtain a more simple expression than that given above, for we get:

$$2KClO_3 + 4HCl = 2KCl + 2H_2O + Cl_2 + 2ClO_2.$$

Here again the "new condition," regulating the decomposition of chlorate of potassium, will be expressed by the quantitative analytical data of the percentages in the reaction products of chlorine and chlorine dioxide. These last examples show already that, as in the application of the familiar phase rule, the appearance of each "new condition" increases by one the number of substances. Designating the number of new conditions by n as in the phase rule, we get for this case the expression:

$$M_n = L + 1 + n.$$

As in the familiar case in the application of the phase rule, we can designate as *non-variant* chemical reactions those following the simple rule $M = L + 1$, as, of course, the formulæ for these reactions do not admit of a variation of coefficients. A chemical reaction obeying the rule $M_n = L + 1 + n$ has n degrees of freedom. Thus the reaction above investigated of the action of sulphuric acid on $K_3Co(CN)_6$, if written according to Treadwell, will have one degree of freedom (inter-relation of the number of molecules H_2O and SO_3), *i.e.* for this case $n = 1$ and thus $M_1 = L + 2$. Accordingly in Treadwell's equation, we have $M_1 = 9$ and $L = 7$.

The reactions of hydrogen peroxide when hydrogen peroxide acts as a reducing agent show this:

$$x_1 Ag_2O + x_2 H_2O_2 = y_1 H_2O + y_2 O_2 + y_3 Ag.$$

In this case $L = 3$ (*i.e.* Ag, H, and O), $M = 5$, *i.e.* Ag_2O, H_2O_2, H_2O, O_2, and Ag. It would seem that this is an exception to the rule; but actually there is no exception, as the last equation is subject to a new condition: the quantity of hydrogen peroxide and the quantity of silver oxide are determined by the fact that the molecule of oxygen is formed by one atom of oxygen taken from the hydrogen peroxide and one atom of the silver oxide. Algebraically this condition can be expressed by putting $x_1 = x_2$. The solution is then quite definite.

Lastly, let us investigate the case of reactions often met with in organic chemistry, where a small number of elements forms a great many substances. We will take the decomposition by water of the alloy of iron and carbon at high temperature and pressure:

$$3Fe_pC_q + 4_pH_2O = pFe_3O_4 + y_2 C_nH_{2n+2} + y_3 C_nH_{2n} + y_4 C_nH_{2n2} + \ldots$$

An immediate application of the rule $M = L + 1$ can be made only in the case of the formation of one hydrocarbon (case of double decomposition), as in the decomposition of the carbide of aluminium. To the other case the rule $M_n = L + 1 + n$ must be applied, as each new hydrocarbon must be characterised by quantitative analytical data showing its percentage in the reaction products in order to be able to write a stoichiometrically correct chemical equation.

The expression $M_n = L + 1 + n$ and the simpler one $M = L + 1$ form the basis for deducing the algebraical equations necessary for the determination of the equation coefficients of a given chemical reaction. The general number of algebraical equations will be equal to $n + L$, where L is the number of equations corresponding to the number of elementids, and n is the number of equations which must be deduced to meet n special conditions.

All the rules given in this paper can be formulated also by a single expression:

$$M_n \leqq A + 1 + n,$$

where A is simply the number of elements taking part in a given chemical reaction.

Mechanism of the Hydrogen Chlorine Combination.

THE object of the present note is to describe some work in progress here on an attempt to test directly the Nernst theory (*Zeit. Electrochem.*, 24, 335, 1918)

for the very wide deviation of the hydrogen chlorine combination from the Einstein photochemical equivalence law. Nernst postulated that the primary action of the light was to split up the chlorine into atoms, and that these were able to react with hydrogen molecules according to the equation

$$Cl + H_2 = HCl + H,$$

and that the atomic hydrogen formed again reacted with chlorine

$$H + Cl_2 = HCl + Cl,$$

and that this cycle was repeated over and over. Hence 1 quantum of light energy was able to cause a very great amount of combination. He showed that all these reactions proceeded with a free energy decrease and hence were possible reactions.

We are attempting to put this theory to a direct test. In our experiments atomic hydrogen, generated by Wood's method (Trans. Roy. Soc., 102-A, 1, 1922), is led into a mixture of hydrogen and chlorine, and if the theory is correct an excessively large amount of hydrogen chloride should be formed. To determine the amount of atomic hydrogen at the moment of reaction the same procedure is used substituting bromine for chlorine. It is known that the hydrogen bromine reaction does not give excessive yields of hydrogen bromide and Nernst has shown that the reaction

$$Br + H_2 = HBr + H$$

will not take place spontaneously. The hydrogen and chlorine are at a partial pressure of about 1 mm. each, and care is taken to prevent illumination of the gas mixture from the discharge tube. It has been shown so far that atomic hydrogen will travel a distance of 15 cm. from the discharge tube when the pressure is 1 mm. If chlorine be permitted to meet the hydrogen stream at this point direct combination takes place at room temperature; in one experiment the yield of hydrogen chloride was 10 per cent. of the hydrogen used. This amount would seem to exceed greatly that due to the atomic hydrogen present, although so far no direct determination has been made of this quantity.

Remarkable Ascending Currents at Melbourne.

REMARKABLE ascending currents were observed during a pilot balloon ascent at Melbourne at 11.00 hours on Friday, October 26, 1923. Heights were determined by means of range-finder readings, and should have no error of consequence. The following table gives the results of the ascent:

Time.		Normal Height.	Observed Height.	Wind.	
				Direction.	Velocity.
min.	sec.	m.	m.	°	m./sec.
	45	90		335	6·8
1	30	180	176	332	10·6
2	15	270	351	325	11·3
3	00	360	801	323	10·9
3	45	450	1202	282	8·3
5	15	630	1580	272	8·8

At the first reading the balloon was too near to be observed with the range-finder. The rate of ascent should have been 100 metres in 45 seconds according to J. S. Dines's formula, but for the particular type of balloon used, range-finder observations indicate that the actual rate is about 90 metres. Shortly after the fifth observation the balloon entered thin cloud, but could be seen for some time longer.

Between the second and last reading the air in which the balloon was travelling ascended at the rate of 4 metres per second, while between the third and fourth the ascending velocity was 8 metres per second. On a number of occasions when cumulus cloud was forming, ascending rates of 2 metres per second over considerable ranges have been observed at Melbourne, but nothing approaching the velocities shown above had been encountered previously. It will be noted that the upward current was at times such that no raindrop could descend through it. A remarkable feature was that the cumulus cloud which was forming rapidly at the time was doing so, not in isolated masses, but in an almost continuous sheet. No cumulo-nimbus was present. Above the cumulus layer alto-cumulus was moving from 252°.

As regards the general situation, an anticyclone was passing to the northwards, moving rapidly. During its passage across the continent the anticyclone had decreased in intensity. Melbourne was coming under the influence of the succeeding low-pressure trough. The recent weather had been characterised by these fast-moving anticyclones, the intervening depressions being very poorly developed. This weather is one of the pronounced drought types.

Long Range α-Particles.

IN a letter to NATURE of September 22, p. 435, we stated that, in addition to the α-rays of range 6·97 cm., radium active deposit emits particles of ranges 9·3, 11·2, and 13·3 cm. respectively. It has since been found that, in addition to the α-rays of ranges 4·8 and 8·6 cm., thorium active deposit emits particles of ranges 11·5 (previously recorded by Rutherford), 15·0 and 18·4 cm. respectively, and that the emission of every 10^6 α-rays of range 8·6 cm. is accompanied by the emission of 220, 47, and 55 particles of the above ranges. In the case of actinium active deposit evidence of particles of range greater than 6·5 cm. was found, but the sources available were not sufficiently intense to allow their range to be determined with accuracy.

By a method devised by Sir Ernest Rutherford we have satisfied ourselves that the long range particles from radium active deposit are α-rays.

Polonium has also been examined and found to emit small numbers of particles of ranges 6·1±0·1, 10·0±0·1 and 13·1±0·2 cm. respectively, in addition to the main group of α-rays of range 3·93 cm. The relative numbers in these new groups are at present being determined; from the brightness of the scintillations it is considered that they are α-rays.

Continental Drift and the Stressing of Africa.

IN reply to Dr. Evans's letter under the above title in NATURE of September 22, p. 438, may I say that I too shall be surprised, indeed extremely surprised, if further work in Uganda does not "disclose the existence of at least some normal faulting with a north and south strike, showing the former existence of east and west tension." Compression in one area seems to imply tension in another; and it is not very

probable that Africa has always been on one side of the equation. But one would expect that, had the continent been "predominantly in a state of tension," evidence of the fact would not be difficult to find in Uganda.

True, there is no reason why "a change of conditions may not convert a true rift valley formed in a period of tension into one bounded by reversed faults." But it may also be observed that it is certain that tension operating on a rift formed by a thrust action would accentuate the features, provided that the bottom of the valley was not prevented by subterranean support from sinking. Compression would do the same without the last proviso; while some such factor as cooling at depth would achieve a similar result without the assistance of either tension or compression if the faults were reversed.

There can be no shadow of a doubt that the bottoms of the Uganda rift valleys have sunk, and that, too, very considerably. What has happened beyond this it is impossible for any living soul to say with absolute certainty at present; but no theory of the rift will pass muster if it leaves Ruwenzori hanging in the air, and if it fails to explain why planes of weakness to tension have not been utilised.

Assuming a rift-block (by which I mean the mass between the rift features) bounded by reversed faults to sink, something must happen to the valley sides; either one or both will subside as a whole, or great lines of normal faulting will appear in the country on one or both sides; or these two things may happen in combination. The first of these alternatives appears, almost to the entire exclusion of the second, by Lake Albert, in Bunyoro; the second, largely to the exclusion of the first, is seen along the eastern side of Lake George. Moreover, normal faulting may appear in the rift-block itself. But all these things may equally be consequent upon settlement of a rift-block bounded by normal faults. Thus it is easily seen that step faulting is not admissible as evidence as to the nature of the fractures that initiated the rift. The solution of the Great Rift Valley problem must be sought, in fact, in places like Bunyoro, where step faulting is almost completely absent.

Dr. Evans, who combines Wegener's general proposition with a tentative theory of the moon's birth, would expect (subject to the truth of the latter) "The chief period of tension in Africa and its surroundings to have existed in Mesozoic and early Kainozoic times"; but this is precisely when, so Prof. J. W. Gregory argues (and I agree with him), Africa was being hunched up by compression.

As to the date of the moon's birth, or the manner of it, I am not qualified to speak with any authority; but I should have thought that had it taken place as late as the Carboniferous period, the parting at least would have been catastrophic. Also I am tempted to ask (not controversially, but as one seeking information) why if "the bulk of the atmosphere" was "attracted towards the protruding mass of the moon," our satellite has now no atmosphere worth mentioning. Did the moon escape without air or water; or may it not be that it once possessed both, self-elaborated very long ago, as those of the earth, in an early stage of its individual career? May not the absence of atmosphere be indicative of completion in the life of a celestial body of a stage the span of which is a function of the sphere's mass?

I fear that I have somehow created the impression that all the major faulting in this part of the world is more or less north and south. This is not so. In Bunyoro certainly, and one has reason to believe elsewhere, a series of very large east to west faults is traceable. This is clearly brought out in a structure map of part of Bunyoro prepared by Mr. W. C. Simmons a few years ago. Judging by the manner in which they cut off the north to south fractures, the east to west faults are the younger; though both are very ancient.

I believe that the word "rift" was originally applied to the Great East African fracture trough, which is quite a different thing from an ocean-covered area produced by the drifting of continents. Rift valley faults will still remain rift valley faults, whether they turn out to be normal or reversed; otherwise "rift valley" must disappear from our nomenclature should my hypothesis prove true.

I thoroughly agree with Dr. Evans's remarks with regard to the value of speculative hypothesis; and, as he reminds us, "It will only be when we have all the facts before us, that we shall be able to solve with any assurance the problems presented by the present configuration of the surface of the globe."

Mahyuro, Lake George, Uganda,
November 3.

Mrs. Hertha Ayrton.

In Nature of December 1 there appears under the above heading an obituary notice of the late Mrs. Ayrton which, I regret to say, is in some matters incorrect and misleading. The article is an unusual one, for in it the writer ventilates his own grievances against his so-called "masters" (The City and Guilds Institute), and disparages and belittles the work and abilities of his lifelong colleagues. To write in this strain about dead friends is in my opinion reprehensible, and it is to be hoped the example will not be followed.

From reading Prof. Armstrong's article one would gather that Mrs. Ayrton had little originality, and that all the scientific work she did was due to her husband's lead. Neither inference would be true, as is proved by the inventions she made before she met Prof. Ayrton and the original work she carried out after his death. In connexion with the latter, Mrs. Ayrton took out eight patents between 1913 and 1918.

The late Prof. Ayrton told me on several occasions that when Mrs. Ayrton took up the study of the electric arc he left the subject entirely alone so that there should be no excuse for any one giving him the credit for her work, and when lecturing to his students on the arc he made similar statements, as many of his pupils can doubtless confirm; it is indeed very probable that Prof. Armstrong heard analogous remarks from Prof. Ayrton's own lips.

A Waltzing Mouse.

It may perhaps be of interest to record that, in some recent experiments in crossing mice, there appeared in a litter of seven (self-coloured champagne) a female which exhibited all the symptoms associated with the Japanese waltzing mouse of which Yerkes made a fairly exhaustive study. It is dextro-rotatory, if the term be permitted. It is not yet old enough for reproduction. Both parents have, however, since produced litters, the female to a Dutch-marked male, the male on a Dutch-marked female, five and four respectively, but all are normal, nor out of eighty mice recently born to other couples have I had any other that waltzes.

Egypt as a Field for Anthropological Research.[1]

By Prof. P. E. NEWBERRY, M.A., O.B.E.

IT has often been stated that civilisation in Egypt spread from the south, and considerable stress has been laid upon the fact that many pre-dynastic and early dynastic remains have been found in Upper Egypt in the region between Edfu and Thinis, especially at Hierakonpolis and Naqada, and north of Naqada, in the neighbourhood of Abydos. Opposite Edfu is a desert route leading to the Red Sea; at Kûft, opposite Naqada, is the beginning of the road leading to Kosêr, the port on the Red Sea. It has been thought that the people who brought culture to Egypt reached the Nile Valley by one or by both these routes from a "God's Land" situated somewhere down the Red Sea coast. But throughout the whole history of Egypt, culture has always come from the north, and spread southwards.

From a study of the monuments of the First Dynasty that had been found at Abydos and elsewhere in Upper Egypt I ventured, nearly twenty years ago, to suggest the existence in pre-dynastic times of a Delta civilisation which, in culture, was far advanced beyond that of Upper Egypt, and I pointed out that it was probably to a Delta civilisation that the Dynastic Egyptians owed their system of writing. I was led to this conclusion by the following facts. Although many pre-dynastic cemeteries had been thoroughly explored in Upper Egypt, no grave had yielded a single fragment of hieroglyphic writing. The only inference that can be drawn from this is that hieroglyphic writing was unknown, or at all events unpractised, by the inhabitants of Upper Egypt before Dynastic times. On the other hand, the discoveries at Naqada, Hierakonpolis, and Abydos had shown us that all the essential features of the Egyptian system of writing were fully developed at the beginning of the First Dynasty. Hieroglyphic signs were already in full use as simple phonograms, and their employment as phonetic complements was well established. Determinative signs are found beginning to appear in these early writings, but, as Erman and Griffith have noticed, even as late as the Fifth Dynasty their use was very restricted in the monumental inscriptions, although they were common in the cursive and freely written texts of the pyramids. At the very beginning of the First Dynasty the numerical system was complete up to millions, and the Egyptians had already worked out a solar year of 365 days. This was indeed a remarkable achievement.

These facts are of great significance, for it is clear that the hieroglyphic system of writing, as we find it at the beginning of the First Dynasty, must have been the growth of many antecedent ages, and yet no trace of the early stages of its evolution have been found on Upper Egyptian soil. There is no clear evidence, however, that the system was borrowed from any country outside Egypt; the fauna and flora of its characters give it every appearance of being indigenous. It is apparent, therefore, that we must seek the cradle of the Egyptian system of hieroglyphic writing elsewhere than in Upper Egypt, and as the fauna and flora of its characters are distinctly Egyptian, the presumption is that it must be located in the Delta. An important indication as to the original home of Egyptian writing is given by the signs which, in historic times, were used to designate the points of the compass. The sign for "east" was a drop-shaped ingot of metal upon a sacred perch, and this was the cult-object of a clan living in pre-dynastic times in the Eastern Delta. The sign for "west" was an ostrich feather placed in a semicircular stand, and this was the cult-object of the people of the Western Delta. The sign for "south" was a scirpus-reed; this was the cult-object of a clan which dwelt on the east bank of the Nile a little above the modern village of Sharona in Middle Egypt. The country south of the apex of the Delta was known as Ta Shema, "Reed Land." It must, therefore, have been at some point north of the apex of the Delta that the scirpus-reed was first used to designate the south. It must also have been somewhere in the Central Delta that the cult-objects of the peoples of the Eastern and Western Delta were first used to designate east and west.

For the Delta being the early home of writing another fact has to be taken into consideration. Thoth, the Ibis-god, was to the Egyptians the god of writing, and it was to him that they attributed its invention. The principal seat of his worship in historic times was Hermopolis, in Middle Egypt. But Thoth's original habitat was situated in the north-east corner of the Delta, where, in pre-dynastic times, had resided an Ibis clan. The tradition that named Thoth as the god and inventor of writing would, therefore, point Delta-wards. This tradition is significant also in another way. Although we cannot doubt that the Egyptian system of writing was evolved in the Delta, the germs of writing may have come into Egypt from Western Asia *via* this north-east corner of the country. In this connexion it may be pointed out that the hieroglyphic signs for "right" and "left" were the same as those for "west" and "east"; the Egyptians who evolved the hieroglyphic system of writing orientated themselves facing south.

It is remarkable that so little is known about the early history of the Delta. Few excavations have been carried out there, and nothing of pre-dynastic, or early dynastic, times has, so far, been brought to light from the country north of Cairo. We do know, however, that before the arrival of the Falcon-kings from Hierakonpolis in the south, Middle and Lower Egypt had been, probably for many centuries, united under one sceptre, and that before these two parts of the country were united there had been a Delta Kingdom which had had its capital at Sais. The names of some of these early kings are preserved on the Palermo fragment of the famous Annals Tablet, and the list there given would alone be enough to prove how ancient the Delta civilisation must have been. There was certainly nothing comparable with it in Upper Egypt in those far-off days.

What were the physical conditions prevailing in the Delta and in the regions to the east and west of it immediately preceding the arrival of Menes in Lower Egypt? For the eastern side the evidence is exceedingly scanty, but there is one fact which is significant.

[1] From the Presidential Address delivered to Section H (Anthropology) of the British Association at Liverpool on September 17.

The chief god of the eastern nomes of the Delta in the Pyramid Age was Anzety, a pastoral deity who was the prototype of Osiris. He is represented as a man holding in one hand the shepherd's crook, and in the other the goatherd's ladanisterion. There can be little doubt, therefore, that in the Eastern Delta there lived a pastoral people who possessed flocks of sheep and goats, and this is evidence of a certain amount of grass-land. In the Central Delta at the same period there lived a series of clans, among which a Bull Clan was predominant. In historic times in Egypt the ox is often figured roaming in papyrus and reed marshes, and it may be that the Central Delta marshes supported herds of domesticated cattle.

Much more is known about the western side of the Delta at the time of Menes. It formed, I believe, part of what was called Tehenu-land; at all events this name was given to the region immediately to the west of the Canopic branch of the Nile. There can be no doubt that this part of the country was a very fertile and prosperous region in the period immediately preceding the First Dynasty. Its name signifies "Olive-land," and we actually see these trees figured, with the name of the country beside them, on a pre-dynastic Slate Palette; on this Palette, above the trees, are shown oxen, asses, and sheep of the type later known as ser-sheep. It was Menes, the Falcon-king of Upper Egypt, who conquered the people of Tehenu-land. This conquest is recorded on a small ivory cylinder that was found at Hierakonpolis. Another record of the southerner's triumph over these people is preserved on his famous Slate Palette; here the Upper Egyptian king is depicted smiting their chieftain, while on the verso of the same Palette is the scene of a festival at the Great Port, which was perhaps situated near the Canopic branch of the Nile. The mace-head of Menes, which is now in the Ashmolean Museum at Oxford, has a scene carved upon it which shows the king assuming the Red Crown of Sais, and the inscription accompanying it records that he had captured 120,000 prisoners, 400,000 oxen, and 1,422,000 goats. This immense number of oxen and goats is clear evidence that the north-western Delta and the region to the west of it (Tehenu-land) must have included within its boundaries very extensive grass-lands.

The history of this part of the Delta is most obscure. During the period that elapsed from the end of the Third Dynasty to the beginning of the Twenty-third, when Tefnakht appears upon the scene, we have scarcely any information about it. What was happening at Sais and other great cities in the north-west of Egypt during the period from 2900 to 720 B.C.? There is an extraordinary lacuna in our knowledge of this part of the country. The people living there were certainly of Libyan descent, for even so late as the time of Herodotus the inhabitants deemed themselves Libyans, not Egyptians; and the Greek historian says that they did not even speak the Egyptian language. The pre-dynastic people who inhabited the greater part of the Lower Nile Valley were apparently of the same stock as these Libyans. There is a certain class of decorated pottery which has been found in pre-dynastic graves from Gizeh in the north to Kostamneh in the south. On this decorated pottery are figured boats with cult-objects raised on poles. Altogether some 170 vases of this type are known, and on them are 300 figures of boats with cult-signs. Of these, 124 give the "Harpoon" ensign; 78 the "Mountain" ensign; and 20 the "Crossed Arrows" ensign. These cult-objects all survived into historic times; the "Harpoon" was the cult-object of the people of the Mareotis Lake region; the "Mountain" and "Crossed Arrows" were the cult-objects of the people dwelling on the right bank of the Canopic branch of the Nile. Thus it will be seen that out of 300 boats figured on vases found in graves in the Lower Nile Valley south of Cairo, 222 belong to cults which can be located in the north-western corner of the Delta. At the beginning of the historic period the cult-objects of the people of the north-western Delta included (1) the "Harpoon," (2) the figure-of-eight "Shield with Crossed Arrows," (3) the "Mountain," and probably (4) the "Double Axe," and (5) a "Dove" or "Swallow." With the exception of the "Harpoon" all these cult-objects are also found in Crete, a fact which is significant in view of Sir Arthur Evans's remark to the effect that he considers the possibility of some actual immigration into Crete of the older Egyptian element due to the first Pharaohs. The "Harpoon," it should be noted, is the prototype of the bident, and later, of the trident of the Libyan god Poseidon. Here in this western side of Lower Egypt is an almost wholly unexplored field for the anthropologist.

I have already referred to the pastoral deity Anzety, who, in the Pyramid Age, was chief of the nomes of the Eastern Delta. Among all the nome-gods he is the only one that is figured in human form; he stands erect holding in his right hand the shepherd's crook, and in his left the goatherd's ladanisterion. On his head is a bi-cornate object that is connected with goats. In the Pyramid Texts, Anzety is entitled "Head of the Eastern nomes," and these included the ancient one of the Oxyrrhynchus-fish, where, later, the ram or goat was the chief cult-animal. Neither the domesticated sheep nor the goat can be reckoned as Egyptian in origin; they both came into Egypt from Western Asia. We have, therefore, in this pastoral deity Anzety evidence of immigration from the west.

Among the cult-objects of the cities over which the god Anzety presided were two which, I believe, can definitely be referred to trees that were not indigenous to the soil of Egypt but to Syria. One of these cult-objects is the so-called Ded-column. This was one of the holiest symbols of the Egyptian religion. It has four cross-bars at the top like superposed capitals. Sometimes a pair of human eyes are shown upon it, and the pillar is draped: sometimes a human form is given to it by carving a grotesque face on it, robing the lower part, crowning the top with ram's horns, and adding two arms, the hands holding the crook and ladanisterion. Frazer has suggested that this object might very well be a conventional representation of a tree stripped of its leaves. That it was, in fact, a lopped tree is, I believe, certain. In the Pyramid Texts it is said of Osiris, "Thou receivest thy two oars, the one of juniper (*uan*), the other of *sd*-wood, and thou ferriest over the Great Green Sea." The determinative sign of the word *sd* is a tree of precisely the same form as the Ded-column that is figured on early Egyptian monuments, *i.e.* it has a long, thin stem.

This tree-name only occurs in inscriptions of the Pyramid Age, and it is mentioned as a wood that was used for making chairs and various other articles of furniture. In the passage quoted from the Pyramid Texts it is mentioned together with juniper, and the latter was employed in cabinet-making, etc., at all periods of Egyptian history. There is no evidence that juniper ever grew in Egypt, but we have numerous records of the wood being imported from the Lebanon region. The *sd*-tree, as we see from the determinative-sign of the name, had horizontally spreading branches, and was evidently some species of conifer. No conifers, however, are known from Egypt; the *sd*-wood must, therefore, have been of foreign importation. As it is mentioned with juniper, which we know came to Egypt from Syria, it is possible that it came from the same region. Among the trees of the Lebanon there are four that have horizontally spreading branches. These are the cedar (*Cedrus libani*), the Cilician fir, *Pinus laricio*, and the horizontal-branched cypress (*Cupressus sempervirens* var. *horizontales*).

Much misconception at present exists with regard to the Lebanon Cedar, because the name "cedar" is applied to a large number of woods which are quite distinct from it, and the wood which we generally call cedar (*e.g.* the cedar of our "cedar" pencils) is not true cedar at all, but Virginian juniper. The wood of *Cedrus libani* is light and spongy, of a reddish-white colour, very apt to shrink and warp badly, by no means durable, and in no sense is it valuable. Sir Joseph Hooker, who visited the Lebanon in 1860, notes that the lower slopes of that mountain region bordering the sea were covered with magnificent forests of pine, juniper, and cypress, "so that there was little inducement for the timber hewers of ancient times to ascend 6000 feet through twenty miles of a rocky mountain valley to obtain cedar wood which had no particular quality to recommend it. The cypress, pine, and tall, fragrant juniper of the Lebanon, with its fine red heart-wood, would have been far more prized on every account than the cedar." The *sd*-tree was, I believe, the horizontal-branched cypress, which is common in the wild state. In the Middle Ages this tree was believed to be the male tree, while the tapering conical-shaped cypress was considered to be the female. This is an interesting fact, because there is some evidence to show that the tapering variety was the symbol of Hathor-Isis, while the horizontal-branched one was the symbol of Osiris.

Not far from the city of Osiris in the Delta was Hebyt, the modern Behbeyt el Hagar. Its sacred name was Neter. The Romans called it Iseum. It was the ancient seat of Isis-worship in Egypt, and the ruins of its temple to that goddess still cover several acres of ground in the neighbourhood. On the analogy of other sacred names of cities the primitive cult-object here was the *ntr*-pole. This was not an axe, as has so often been supposed, but a pole that was wrapped around with a band of coloured cloth, tied with cord half-way up the stem, with the upper part of the band projecting as a flap at top. Dr. Griffith conjectured that it was a fetish, *e.g.* a bone carefully wound round with cloth, but he noted that "this idea is not as yet supported by any ascertained facts." As a hieroglyph this wrapped-up pole expresses *ntr*, "god," "divine," in which sense it is very common from the earliest times; gradually it became determinative of divinity and of the divine names and ideographic of divinity. Another common ideograph of "god" in the Old Kingdom was the Falcon (Horus) upon a perch, and this sign was also employed as a determinative of divinity and of the names of individual gods; it even sometimes occurs as a determinative sign of the *ntr*-pole, *e.g.* Pyr. Texts, 482. This use of the Falcon indicates that in the early dynasties the influence of the Upper Egyptian Falcon-god (Horus) was paramount.

There is reason, however, for believing that the *ntr*-pole cult had at an earlier period been the predominant one among the writing people of the Delta; this, I think, is shown by the invariable use of the *ntr*-pole sign in the words for priest (*hm-ntr*, god's servant) and temple (*ht-ntr*, god's house). Now, on a label of King Aha of the First Dynasty there is a representation of the temple of Neith of Sais. Here two poles with triangular flags at top are shown on either side of the entrance. Later figures of the same temple show these poles with the rectangular flags precisely as we find in the *ntr*-sign. A figure of the temple of Hershef on the Palermo Stone shows two poles with triangular flags, while a Fourth Dynasty drawing of the same temple shows the same poles with rectangular flags. We see, therefore, that the triangular-flagged pole equals the rectangular-flagged one, and that the *ntr* is really a pole or mast with flag.

Poles of this kind were probably planted before the entrances to most early Egyptian temples, and the great flag-masts set up before the pylons of the great temples of the Eighteenth and later dynasties are obviously survivals of the earlier poles. The height and straightness of these poles prove that they cannot have been produced from any native Egyptian tree; in the Empire, flag-staves were regularly imported from Syria; it is probable, therefore, that in the earlier times they were introduced from the same source. A well-known name for Syria and the east coast of the Red Sea, as well as of Punt, was Ta-ntr, "the land of the *ntr*-pole." This was the region in which the primitive Semitic goddess Astarte was worshipped. In Canaan there was a goddess Ashera whose idol or symbol was the ashera pole. The names of Baal and Ashera are sometimes coupled precisely as those of Baal and Astarte, and many scholars have inferred that Ashera was only another name of the great Semitic goddess Astarte. The ashera-pole was an object of worship, for the prophets put it on the same line with the sacred symbols, such as Baal pillars; the ashera was, therefore, a sacred symbol, the seat of a deity, the mark of a divine presence. In late times these asherîm did not exclusively belong to any one deity; they were erected to Baal as well as to Yahw. They were sign-posts set up to mark sacred places, and they were, moreover, draped. They correspond exactly to the *ntr*-poles of Egyptian historic times.

I have noted that these *ntr*-poles were tall and straight. What tree produced them? In Egyptian inscriptions there is often mentioned a tree named *tr.t*. It was occasionally planted in ancient Egyptian gardens, and specimens of it were to be seen in the Temple garden at Heliopolis. The seeds and sawdust were employed in medicine, and its resin was one of

the ingredients of the Kyphi-incense. Chaplets were made of its twigs and leaves. The tree was sacred to Hathor; branches of it were offered by the Egyptian kings to that goddess. In a Saite text it is mentioned with three other trees, pine, yew, and juniper; these are all found in Northern Syria, where they grow together with the cypress; the *tr.t* tree may therefore be the cypress. Evidence has been brought forward to show that the *sd*-tree is the horizontal-branched cypress, which was believed to be a male tree, while the tapering, flame-shaped cypress was believed to be the female tree. The Ded-column was the symbol of Osiris, and at Busiris a festival of raising this column was celebrated. The *tr.t* tree was sacred to Hathor, who is often identified with Isis, and there was a festival of raising the *tr.t* tree that was celebrated on the nineteenth day of the first month of the winter season. It is not known where this festival was celebrated, but it may well have been at Neter, the seat of the Isis cult near Dedu-Busiris. The two tree-cults point to Northern Syria as the country of their origin.

In the architecture of ancient Egypt two distinct styles can be recognised. One is founded on wattle-and-daub, the other on wood construction. Wattle-and-daub is the natural building material of the Nile Valley and Delta, and the architectural forms derived from it are certainly indigenous. Those styles derived from wood construction, on the other hand, could not have originated in Egypt; they must have arisen in a country where the necessary timber was ready at hand. Egypt produces no coniferous trees and no timber that is at all suitable for building purposes, or indeed for carpenter's work of any description. The wood of the sycomore-fig is very coarse-grained, and no straight planks can be cut from it. The sûnt-acacia is so hard that it requires to be sawn while it is green; it is very irregular in texture, and on account of the numerous branches of the trunk it is impossible to cut it into boards more than a couple of feet in length. The palaces of the early kings of the Delta were built of coniferous wood hung with tapestry-woven mats. The tomb of Menes' queen, Neith-hotep, at Naqada, was built of brick in imitation of one of these timber-constructed palaces, and smaller tombs of the same kind are known from the Second and Third Dynasties, but not later. As early as the reign of King Den (First Dynasty) the palaces of this type were beginning to be built of the native wattle-and-daub in combination with wood, and by the end of the Pyramid Age the style disappears entirely, though the memory of it was preserved in the false-doors of the tombs and stelæ. Brick buildings similar to those of the "palace" style of Egypt are also known from early Babylonia, and they were at one time regarded as peculiarly characteristic of Sumerian architecture. These, obviously, must have been copied, like the Egyptian, from earlier timber forms. In Babylonia, as in Egypt, timber was scarce, and there are records that it was sometimes obtained from the coast of Syria. This was the region from which the Egyptians throughout historic times obtained their main supplies of wood, so it is not improbable that they, as well as the Sumerians, derived this particular style of architecture from Northern Syria. I may observe in passing that in this "palace" style we have the transition form between the nomad's tent and the permanent building of a settled people.

The lack of native timber in Egypt is significant in another direction. Boats of considerable size are figured on many pre-dynastic monuments. They are long and narrow, and in the middle there is usually figured a reed or wicker-work cabin. In my view these boats were built, like many of those of later periods in Egypt, of bundles of papyrus reeds bound together with cord; they were, in fact, great canoes, and, of course, were only for river traffic. They were not sailing boats, but were propelled by means of oars. No mast is ever figured with them, but they generally have a short pole amidships which is surmounted by a cult-object. On one pre-dynastic vase there is a figure of a sailing ship, but this is totally different in build from the canoes, and it has a very high bow and stern with its mast set far forward in the hull. Similar vessels are figured on the ivory knife-handle of pre-dynastic date from Gebel el Araq, but these vessels appear to be in port and the sails are evidently lowered.

I have already referred to the Great Port mentioned on the Palette of Menes. A port implies shipping and trade relations with people dwelling along the coast or across the sea. It may be that the people of the north-western Delta built wooden ships, but if they did they must have procured their timber from some foreign source. Coniferous wood was already being imported into the Nile Valley at the beginning of the First Dynasty from the Lebanon region, and it must be remembered that the Egyptian name for a sea-going ship was *kbnyt*, from Keben, "Byblos," the port of the Lebanon, where these ships must have been built and from whence they sailed. The sacred barks of the principal gods of Egypt in historic times were invariably built of coniferous wood from the Lebanon. Transport ships on the Nile were sometimes built of the native sûnt-wood, and Herodotus describes them as made of planks about two cubits long which were put together "brick-fashion." No masts or sail-yards, however, could possibly be cut from any native Egyptian tree. In the Sûdan at the present day masts are sometimes made by splicing together a number of small pieces of sûnt and binding them with ox-hide, but such masts are extremely liable to start in any gale, and they would be useless for sea-going ships. It may be doubted whether the art of building sea-going ships originated in Egypt.

It may be doubted also whether the custom of burying the dead in wooden coffins originated in Egypt. In countries where a tree is a rarity a plank for a coffin is generally unknown. In the Admonitions of an Egyptian Sage written some time before 2000 B.C., at a period when there was internal strife in Egypt, the Sage laments that "Men do not sail northwards to [Byb]-los to-day. What shall we do for coniferous trees for our mummies, with the produce of which priests are buried, and with the oil of which [chiefs] are embalmed as far as Keftiu? They come no more." This ancient Sage raises another anthropological question when he refers to the oil used for embalming. The only oils produced by native trees or shrubs in Egypt were olive oil, ben oil from the moringa, and castor oil from the castor-oil plant. The resins and oils used for embalming were principally

those derived from pines and other coniferous trees. Egypt produced no kinds of incense trees or shrubs. The common incenses were pine resin, ladanum, and myrrh, and all these were imported. It is difficult to believe that the ceremonial use of incense arose in Egypt.

These are a few of the questions raised by a study of the material relating to the origins of the ancient civilisation of Egypt. An immense vista has been opened out before our eyes by the discoveries of the last thirty years, and now, in Egypt better than in any other country in the world, we can see man passing from the primitive hunter to the pastoral nomad, from the pastoral nomad to the agriculturist, and then on to the civilised life which begins with the art of writing. We can see in the Delta and in the Lower Nile Valley tribes becoming permanently settled in fixed abodes around primitive cult-centres, and then uniting with others into one community. We can trace the fusion of several communities into single States, and then, later, the uniting of States under a supreme sovereign. What other country in the world preserves such a record of its early history?

Rare Gas Discharge Lamps.

By J. W. RYDE, Research Laboratories of the General Electric Company, Ltd., Wembley.

A DISCHARGE of electricity through a gas at atmospheric pressure generally takes the form of a luminous spark which will pass only under a potential gradient of several thousand volts per centimetre. If, however, the pressure of the gas is reduced, the appearance of the discharge changes. First it spreads out into wavy streamers; the streamers then broaden until the discharge tube is filled with a diffuse luminous glow extending from the positive electrode to within a short distance of the cathode. This glow is known as the positive column. The cathode is now covered with a layer of bright luminosity called the negative glow, and on close inspection is seen to be not quite in contact with the electrode but separated from it by a thin and sharply defined region, known as the Crookes's dark space. Another less well-defined dark region, the Faraday dark space, is between the negative glow and the positive column. Further reduction of the pressure results in a widening of both dark spaces and the negative glow, the positive column at the same time becoming correspondingly shorter. At still lower pressures the Crookes's dark space increases until finally it fills the whole tube and there is no further luminosity of the gas.

The potential necessary to start the discharge depends on the pressure and nature of the gas, the form and material of which the electrodes are made, and also on the distance between them. In a given gas with given electrodes the starting potential is large at high pressures, but decreases, in an almost linear relation, with decrease of pressure, reaching a minimum at what is called the critical pressure, after which it rises again very rapidly. The pressure at which the minimum occurs depends on the form of the electrodes, their distance apart and the nature of the gas, but the minimum itself depends on the nature of the gas and the material and form of the cathode employed. It is about 200 volts for neon, 280 volts for hydrogen, 340 volts for air, and 420 volts for carbon dioxide. Small traces of impurity affect these values to a great extent; thus, the addition of only 0·5 per cent of pure hydrogen to neon reduces the minimum starting potential by nearly 50 volts, 5·0 per cent reduces it by about 60 volts, but if more than 5·0 per cent is added the hydrogen ceases to act as an impurity and begins to show its own characteristics, so that the starting voltage rises again. On the other hand, small quantities of other gases, such as oxygen, raise the starting potential instead of lowering it. The material of which the cathode is made has also some effect. The figures given above refer to cathodes of ordinary metals such as iron, nickel, or copper, etc., between which there are only small differences, but with magnesium, barium, or the alkali metals the starting voltage is considerably reduced; in fact, with certain alloys of these metals, the glow discharge can be started in neon at a potential so low as 90 volts and may be maintained at 58 volts.

When once the discharge has started, the potential can be lowered somewhat before the discharge stops.

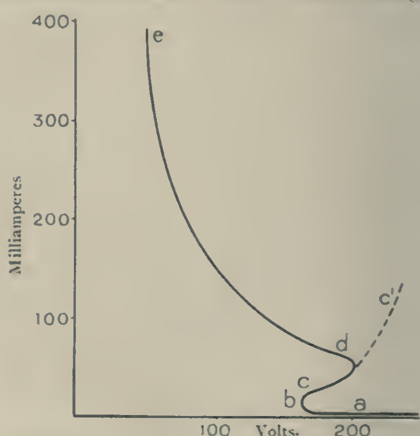

FIG. 1.

The curve connecting this "going out" voltage and the pressure is roughly similar to the starting voltage curve, but is displaced to a position somewhat below it on the voltage ordinate.

If the electrodes are only a short distance apart, so that the positive column is absent, the relation between the current flowing and the potential applied across the electrodes is that shown in Fig. 1. The states represented by the lower and upper parts of the curve are unstable, and can be observed only if there is in series with the discharge an appropriate resistance, by means of which the current may be varied. With this arrangement, when the current is only of the order of a microampere, a faint glow is seen some distance from the cathode. The potential between the electrodes falls rapidly as the current is increased, and at the same time the glow becomes brighter and assumes the form of a sharply defined patch moving nearer and nearer to the cathode as the current rises. The voltage now remains sensibly constant, being that known as the normal cathode fall, which is the lowest potential at which

the unsupported discharge can be maintained. With a further increase of current, the glow spreads laterally over the cathode, its intrinsic brilliancy and the current density remaining practically constant. A value of the current is eventually reached at which the cathode becomes completely covered with a layer of glow separated from it by the Crookes's dark space, which is only a fraction of the width of the layer of glow itself. Any further increase in current brings us to the part *c* of the curve; the voltage now increases with increase of current and the glow becomes brighter and the dark space narrower. The curve eventually becomes very steep, following the path *cc′*, and currents of the order of several amperes per square centimetre of cathode surface can be passed. At some part of the curve *cc′* the cathode begins to heat up considerably, and if composed of a refractory metal such as tungsten, will become white-hot; thermionic emission then takes place and the glow discharge passes over to the arc discharge. As soon as this begins the potential difference between the electrodes begins to decrease as the current rises, and may finally drop to only a few volts.

Gas discharge lamps may be divided into three classes, namely: (1) Lamps in which practically all the light is emitted by the positive column, (2) negative glow lamps in which the positive column is absent, and (3) lamps in which the light is emitted not from the gas but from the cathode itself, which is rendered incandescent by the discharge.

Lamps of the Moore type belong to the first class. They consist of a long glass tube filled with gas to a pressure of a few millimetres and having an electrode at each end. On account of the distance between the electrodes, the operating potential usually amounts to several thousand volts and is inconveniently high. Recently, short tubes of this type containing neon, and having electrodes made of alkali metal alloys, have been developed which will run on 220 volt A.C. supply, but require a special device giving a higher voltage for starting. These lamps are very efficient; with some of the tubes an efficiency of 0·65 watts per candle is obtainable. The colour of the light, however, is a brilliant orange red, which for many purposes is objectionable.

The second class of lamp was developed to run directly on ordinary lighting circuits. The electrodes are placed a few millimetres apart in a small bulb, the distance between them being such that the positive column is absent; this is to enable them to start and run at ordinary supply voltages. The gas used for filling the lamps is neon with about 20 per cent. of helium, which is separated with it during the process of extraction from the air. The advantages of neon are threefold. In the first place, most of the energy radiated from the glowing gas lies in the visible spectrum; secondly, the starting potential is lower than in other gases; and thirdly, the colour of the light emitted, being a yellow orange, is more suitable for illumination purposes than that from any other gas. By using hydrogen to reduce the starting voltage as explained above, and by filling the lamps to about the critical pressure (10 mm.), it is possible to make lamps having iron electrodes in which the discharge will start at about 150 volts.

The whole of the light from these lamps comes from the negative glow, which appears as a layer of bright orange luminosity about two millimetres thick completely covering the cathode, whatever its size or shape. The Crookes's dark space at the pressure used is only a fraction of a millimetre thick and is not easily seen. In consequence, the luminosity takes the form of the cathode, so that if this electrode is formed out of a sheet of metal in the shape of a letter, numeral, or similar sign, it will appear brilliantly illuminated when the discharge is passing. It is in this form that the tube is used for advertising purposes. In cases where the lamp is required for dim illumination, the cathode is made of a spiral of wire in the shape of a beehive, which ensures an approximately even distribution of light in all directions. The other electrode is either an iron wire hidden behind the letter, or a plate inside the spiral. On direct current only one electrode becomes illuminated, but on alternating current the small electrode also glows during the half cycle when it becomes the cathode.

On account of the rigidity of the mechanical construction, the lamps are robust and their life is limited only by their progressive blackening. This blackening is due to particles of the cathode which are shot off during the passage of the discharge and collect in the form of a film on the bulb. The rate at which the blackening takes place depends on the current passing through the lamp, and also varies very greatly with the particular metal used for the electrodes and the nature of the gas. The addition of impurities which lower the starting potential of the gas also considerably reduces the blackening. Thus, with iron electrodes and pure neon, the useful life of the lamp would only be about 80 hours, while with an addition of a small percentage of hydrogen the life becomes of the order of 1000 hours or more. A series resistance placed in the caps of the lamps makes them suitable for various voltages, and at the same time reduces the current to a value leading to a reasonable life.

These lamps, in common with all forms of Geissler discharge tubes, possess many properties which are valuable for purposes other than that of lighting. For example, when running on the part *ab* of the curve of Fig. 1 they can act as a negative resistance and can be used to generate oscillations. They are also sensitive detectors of current; the luminosity produced by a current of one microampere is easily seen if the lamp is shielded from direct daylight. But these other developments cannot be treated here.

In the third class of lamp, the electrodes are usually tungsten spheres about one millimetre in diameter and placed one millimetre apart. The bulb is filled with neon to about 50 mm. pressure. When first switched on, an intense glow discharge takes place which heats the cathode white-hot; a thermionic emission then ensues and the potential across the lamp drops to about 25 volts, the current being 1·0 to 1·25 amperes, the remaining volts being dropped in the series resistance. The lamp at this final stage operates in the region *e* of the current voltage curve shown in Fig. 1. The white-hot tungsten ball acts as a very intense point source of light suitable for projection purposes. The Pointolite lamp is a variant of this form, in which the discharge is initiated by means of a tungsten spiral heated electrically, the heating current being cut off when the lamp has started.

Obituary.

Lieut.-Col. H. H. Godwin-Austen, F.R.S.

The death, on December 2, of Lieut.-Col. Henry Haversham Godwin-Austen in his ninetieth year removes the last of the great pioneers in the geography of the Himalaya and a leading authority on Indian Mollusca. Col. Godwin-Austen was born at Teignmouth, July 6, 1834. He was a fellow-student with Lord Roberts at Sandhurst, whence they both went to India at the end of 1851. Godwin-Austen saw service the next year in the second Burmese War. His scientific tastes, which were hereditary—for his father, R. A. C. Godwin-Austen, was a geologist who has left an enduring reputation owing to his exceptional insight—led him in 1857 to join the Indian Survey Department. It was his privilege to survey northern Kashmir, where he discovered the Baltoro, Hispar, and Biafra Glaciers—the greatest group of valley glaciers in the world. They were afterwards traversed and mapped by Sir Martin Conway, who named the tributary glacier to the Baltoro from K_2 the Godwin-Austen glacier. The glaciers were described by Godwin-Austen in a short paper in the Proceedings of the Royal Geographical Society (vol. viii., 1864), the discussion on which is remarkable for Falconer's advocacy of the pre-glacial age of the Alpine lake basins and their preservation by the protective action of glaciers. During this survey Godwin-Austen fixed the position and heights of many of the giant peaks of the Karakorums, including K_2, which had been previously discovered by Montgomerie. It is often known as Mt. Godwin-Austen, and according to the heights adopted by the Indian Survey Department is the second highest mountain in the world.

While Godwin-Austen was working in this district he made many mountain ascents, of which his highest was on Mata, 20,600 ft., in 1862. In 1863–64 he was engaged in the survey of the eastern parts of the Himalaya around Darjeeling and in Bhutan, and, later still, further east on the Khasia Hills and in Assam. His views on the geographical structure and classification of the Himalaya were stated forty years ago in his presidential address to the Geographical Section of the British Association, which is his most important geographical paper. He contributed to the Geological Society several papers which made important additions to the geology of the Himalaya, including the discovery of the extension into Kashmir of the Spiti series, the most significant horizon in the Himalaya. In 1884 he described the drifts exposed in a new railway cutting near his home at Guildford, and the paper was illustrated by sections, characterised by the same precision and detail as those issued with his Indian papers.

After leaving the Indian Survey, Godwin-Austen's main interest was in the land mollusca. He was described as having "a unique knowledge of Indian molluscs." He contributed to "The Fauna of British India" the volume on the Testacellidæ and Zonitidæ. The value of his work on that group is shown by his election as president of the Malacological Society in 1897–9, and of the Conchological Society in 1908–9. His later years were burdened by financial embarrassment due to an unfortunately worded will. He inherited the paternal estate of Shalford, which proved a vampire instead of the source of a comfortable income. His interest was subject to fixed charges which, when the value of land fell, used up more than the whole of the income from the property. He bore this trouble with his characteristic courage and cheerfulness. Great sympathy was also recently felt for him, owing to the unfortunate loss of the portofolio of sketches and maps made during his Kashmir service, sixty years ago.

Godwin-Austen was elected F.R.S. in 1880, and received a belated Founders' Medal from the Royal Geographical Society in 1910.

Herluf Winge.

It is with much regret that we record the sudden death, on November 10, at Copenhagen, of Herluf Winge, who for many years, and until his death, was "Viceinspektor" in the Zoological Museum of the University of Copenhagen. As a lad Winge began to study the small mammals of Denmark, and his earliest papers upon this subject were full of promise. A little later, in 1877, while still a student in the University of Copenhagen, he published an account of some of the skull characters in the mole, shrew, and other Insectivora, in which he displayed not only remarkable learning but a most clever technique. In 1882 he gave his views upon the mammalian dentition and his theory of cusp homologies in a paper which will ever be regarded as a classic. In the same year appeared an account of a collection of mammals from Greece; and in preparing this Winge was led so far afield investigating the relationships and special adaptations of the species before him that he himself regarded this piece of work as the foundation of the important publications next to be noticed.

Between 1887 and 1915 Winge published a series of works which ostensibly are descriptions of the fossil bones collected by Lund in the caves of Lagoa Santa, Minas Geraes, Brazil, and of the recent mammalia obtained in the same region by Lund and Reinhardt. Taking these mammals order by order (Rodents, 1887; Chiroptera, 1892; Carnivora, Primates, 1895; Marsupials, including Monotremes, 1897; Ungulates, including Sirenia, 1906; Edentates, 1915), Winge commenced each memoir with a description of the Brazilian material; but, that finished, he proceeded in each case to give a review of the whole order, bringing out his views of the evolution and relationships of the orders and of every fossil and living family and genus in a wonderfully clear and concise style. He seems to have prepared a complete monograph of each genus dealt with; and then to have compressed each monograph into a short paragraph and very often into a single sentence. But in this small space he contrives not only to state all that is essential, but to throw many a brilliant beam across what was previously obscure. Companion reviews of the Insectivora (1917) and the Cetacea (1919), the two orders not represented in the Lagoa Santa material, have since been published by Winge. That dealing with the Cetacea has recently been translated from the Danish by Mr. G. S. Miller

and published in the Smithsonian Miscellaneous Collections.

A collected and revised edition of these reviews, in three volumes, under the title of "Pattedyr-Slægter," is at present passing through the press; and the first volume of this work was received in London on the day before Winge's death. This new and more convenient edition will be welcome, for it is but bare justice to state that the reviews in question constitute together the finest, most comprehensive, and most inspiring technical account of the class Mammalia that has ever been written.

Many other papers dealing with the mammals of Greenland and the fossil mammals and birds of Denmark were published by Winge. In 1908 he contributed the volume on Danish Mammals to the series of handbooks entitled "Danmarks Fauna"; and this little book, illustrated by Winge himself, is at once admirable and inimitable.

Reviewing the whole of Winge's published work, one cannot fail to be struck by an extraordinary fact. It is that in his writings one does not mark the flight of time. He seems to have acquired his full mental power and his own peculiar way of looking at things at an extremely early age; for his early papers of 1877 and 1882 read to-day, exactly like that of 1919, as the work of a great master. M. A. C. H.

WE regret to announce the following deaths:

Prof. F. Clowes, emeritus professor of chemistry and metallurgy and first principal of University College, Nottingham, and the author of well-known text-books on analytical chemistry, on December 18, aged seventy-five.

Canon T. Wood, well known for his natural history studies, on December 13, aged sixty-one.

Current Topics and Events.

Two octogenarian fellows of the Royal Society celebrated their birthdays this week. Sir Archibald Geikie, O.M., the Nestor of British geology, who was elected to the Royal Society so long ago as 1865, attained the age of eighty-eight on December 28, and another distinguished geologist, Sir W. Boyd Dawkins, elected to the Society in 1867, was eighty-five on December 26. To both of them the congratulations of all scientific workers will be heartily accorded. Sir Archibald Geikie, who figured as a "Scientific Worthy" in NATURE thirty-one years ago (January 5, 1893), has a world-wide reputation. As a geologist, and as the author of the "Text-book of Geology," originally published in 1882, and of other standard works on geology and geography, he is known everywhere. This is in great measure due to the way in which Sir Archibald is able to quicken interest in his subject by the expression of his deep and intense feeling for Nature. No one has done more to link geology with appreciation of the natural beauty of scenery. His work as an original investigator in geology and as a writer of inspiring volumes on this subject and on physical geography won for him the Royal medal of the Royal Society in 1896. From 1908 until 1913 Sir Archibald served as president of the Royal Society, while he was president of the British Association at the Edinburgh meeting in 1892. For the period 1882–1901, he was Director-General of the Geological Survey of the United Kingdom and Director of the Museum of Practical Geology. In spite of his advanced age, Sir Archibald maintains his active interest in both science and literature, and so recently as 1918 he produced a notable volume of Memoirs of John Michell, who died in 1793, one of the early workers in geology.

SCIENTIFIC societies and other bodies organising conferences for next year should know that the authorities of the British Empire Exhibition to be held at Wembley have constructed an admirable congress building containing four conference halls, with appropriate committee rooms, etc., capable of seating 2140, 550, 180, and 150 persons respectively. These halls are being allocated to responsible organising committees free of charge, and early application should be made for the use of any of them, as the dates are being filled up rapidly. The following scientific and technical societies, among others, have already booked one or more of the halls for conferences on different dates: The British Engineers' Association, the British Electrical and Allied Manufacturers' Association, the Institution of Sanitary Engineers, the Textile Institute, the Society of Dyers and Colourists, the North-East Coast Institution of Engineers and Shipbuilders, the Institution of Automobile Engineers, the Museums Association, the Horace Plunkett Foundation, the Health Propaganda Association, the Association of British Chemical Manufacturers, the Institution of Mining and Metallurgy, the Municipal Electrical Association, the Electrical Contractors' Association, and the Gas Association. Applications for use of the halls on dates still open should be sent to the Secretary, Conference Committee, British Empire Exhibition, 16 Grosvenor Gardens, London, S.W.1.

WITH the approaching retirement of Prof. S. Alexander from its chair of philosophy, the University of Manchester loses the services of one of the most original of the elder generation of thinkers. Nearly fifty years ago, he came from Australia to Oxford, where he gained reputation by a rare power of winning first classes. He soon, however, deserted other pursuits for philosophy, and won an assured position before he was thirty by his remarkable book on "Moral Order and Progress." Called in 1893 from a tutorship at Lincoln College to succeed Robert Adamson at Manchester, he has represented philosophy there for more than thirty years. At Oxford he was conspicuous in the reaction against the philosophy of T. H. Green, and was among the first to preach to an unheeding university the importance of modern psychology. But he never lost a bent for metaphysics and for vigorous thinking about fundamentals. His philosophic position was fully revealed in his Gifford lectures at Glasgow on "Space, Time, and Deity," published in 1920. A book so technical defies

analysis, and it is enough to say that, though many disagreed with his doctrine, there was an absolute consensus among experts that it was a contribution of the first importance to philosophic thought. Yet few philosophers have lived less in the clouds, and Alexander has not only discharged meticulously the duties of an exacting chair, but has also been prominent in many university and public activities. Ever a keen champion of the higher education of women, he took a foremost part in the foundation of Ashburne Hall, the women's hall of residence, the secretaryship of which he is resigning on his retirement from university life.

The first part of the funeral service for Canon T. G. Bonney was held in the Chapel of St. John's College, Cambridge, on December 12. Among those present were the following fellows of the Royal Society: Prof. A. C. Seward and Prof. J. E. Marr (Geological Society), Mr. C. T. Heycock (Cambridge Philosophical Society), Prof. E. J. Garwood (Alpine Club), Sir Clifford Allbutt, Prof. H. F. Baker, Mr. F. F. Blackman, Sir Joseph Larmor, Dr. G. D. Liveing, Sir Ernest Rutherford, Prof. W. T. Sollas, Sir Joseph Thomson, Prof. W. W. Watts, and Prof. J. T. Wilson.

The Council of the Royal Meteorological Society has awarded the Symons gold medal for 1924 to Dr. Takematsu Okada, Director of the Central Meteorological Observatory, Tokyo, Japan. The medal is awarded for distinguished work in connexion with meteorological science, and will be presented at the annual general meeting on January 16.

The discussion before the Illuminating Engineering Society on December 11 was concerned with a problem that confronts many of those who are associated with applied science—the best method of disseminating technical information amongst the general public. Illumination involves an appeal to the eye, and influence is best brought to bear through the medium of actual demonstrations of good and bad methods of lighting. Details of actual experience in practice, for example, of improved output and greater freedom from accidents resulting from better lighting, are also of great value. But in order to be convincing, such data must be derived from scientifically conducted tests and backed by recognised authority. Mr. Dow mentioned some of the work which the Society is doing in this connexion—for example, in co-operation with representatives of the printing trade and with the British Industrial Safety First Association. A considerable part of the discussion was devoted to the question of the high values of illumination now being advised in some quarters. The view was expressed that such recommendations must be based on scientific method, and that the desired conditions are best ascertained by experiments conducted with the aid of leading industrial councils. This same point also came up for consideration in a discussion initiated by Mr. W. P. Fanghaenel and Mr. W. N. Booth before the Institution of Civil Engineers on December 12, when Mr. L. Gaster explained the procedure of the Home Office Departmental Committee concerned with industrial lighting and emphasised the distinction between values desirable in practice and legal minima.

In order that donors might have the opportunity of seeing the premises and the equipment of the Department of Glass Technology at the University of Sheffield, a series of luncheons have been arranged, the first having been given by Mr. W. F. J. Wood, chairman of the Glass Research Delegacy, on November 15, and the second of the series by Prof. W. E. S. Turner, president of the Society of Glass Technology, on December 13. The new premises, which cover three-fourths of an acre, were, until the end of 1920, in occupation as an actual glass works. Since being purchased at a price of 9000*l*., considerable alterations have been made, a set of laboratories and small library constructed, whilst the other buildings have been adapted and equipped with plant for experimental glass melting. In this connexion there are furnaces capable of melting glass on any scale between a few grams and about 120 lb., the firing being by town's gas and compressed air, whilst a large two-pot recuperative furnace fired by oil has a capacity of two pots each of about 15 cwt. There are, in addition, a block of buildings devoted to the making of all sizes of clay pots, store rooms for the glass-making materials, a room for mixing, a machine room, smith's shop, compressor house, etc. Courses of instruction lead to the degree of B.Sc.Tech. and higher degrees. In addition, however, to the normal teaching work of the Department, a great deal of experimental work has been done for individual manufacturing firms, whilst since 1917 no fewer than 96 papers involving research have been published from the Department. The Department has no endowment, but the glass industry has been very appreciative of the work done and has contributed generously towards its maintenance.

Mr. T. W. T. Tuckey, who was in Japan at the time of the great earthquake, had an opportunity shortly afterwards of visiting both Tokyo and Yokohama, and gives the results of his observations in *Engineering* for November 30. The framework of the ordinary Japanese house is made of very light uprights secured, by tenons only, to other light horizontal members at the floor and ceiling. The floors and ceilings are wood, and the inside divisions are of wood and paper. When a severe shock causes the tenons to break, the structure closes up and pins down any occupants who do not escape quickly. The charcoal fires are also pinned and thus fires are started. It is almost inconceivable that up to August 31, 1923, such buildings were still being constructed in the capital city of Tokyo. Temples are also built of wood and have nothing but horizontal and vertical timbers in their construction; the timbers, however, are very massive, and such buildings stand up well against earthquakes and storms. In Tokyo, the first brick buildings of any importance were put up by the Government; nearly all these buildings survived the shock, though a few were burned. It will be remembered that the fires, started by the collapse of the more flimsy buildings, destroyed a large part of Tokyo. Tokyo station

building, three and four stories high and some hundreds of feet long, constructed of red brick, was not damaged by either earthquake or fire. Reinforced concrete buildings in Tokyo did not come off so well as the better-class brick buildings. Much of the brick facing has come away and there are cracks in the concrete. They are, however, probably the safest buildings for the inhabitants, and office buildings of this class have continued in use without interruption. The behaviour of steel frame buildings was peculiar; from a few feet above the ground the brickwork is cracked, and this continues for two or three stories. Above the third and up to the top (in some cases eight stories) no damage whatever is to be seen. The writer was nowhere able to find the slightest sign of failure of the foundations of any building, whether wrecked or standing.

The report for 1922 of the director of the Bernice Pauahi Bishop Museum at Honolulu has recently been issued. It gives a summary of the various activities of the Museum officials in researches relating to the natural history of the Pacific Islands and the culture and folk-lore of the Hawaiians and other Polynesian people. A number of expeditions for systematic survey in anthropology, botany, and zoology have been undertaken in connexion with the Museum. The most important were the Whitney South Sea expedition, an expedition to Fanning Island, the exploration of Guam in the Ladrone Islands, and the Bayard Dominick expedition for the investigation of the origin, migration, and culture of the Oceanic people. Some interesting general conclusions have been reached by the members of the Dominick expedition with regard to the Polynesian population. There seem to be two basic elements. The first is Caucasian with physical characteristics approaching some Mongols, with tall stature, moderately long heads, relatively high narrow faces and noses, light brown skin, and straight or wavy black hair. The second element is the Indonesian typical of Celebes, with shorter stature, low broad faces, wavier hair and darker brown skin. A third element is found only in small numbers with very short heads, narrow faces, and light skin. The second type is characterised by a higher social and religious development than the first. The first type is universally distributed in the Pacific, but strongest in New Zealand and the Marquesas. The second type is prevalent in North and Central Polynesia. In the report Mr. J. F. Illingworth notes that the Hawaiian house-fly is not the same as that of Europe and the United States, but is a variety found on the western shores of the Pacific. As it is known that these flies follow man, and there were house-flies in Hawaii when Captain Cook arrived, the inference is drawn that the original immigrants and the flies came to Hawaii from the west.

Applications are invited by the secretaries of the Royal Society for the Armourers and Brasiers' Company research fellowship in metallurgy, tenable in the first instance for two years, with a possible extension to five years. The research undertaken by the successful candidate must be connected with base metals and alloys, preferably those used in the ancient crafts of the Company of Armourers and Brasiers. The annual value of the fellowship is 500*l*. Applications must reach the secretaries of the Royal Society, Burlington House, W.1, by March 1 next.

We have received the annual report of Livingstone College, Leyton, for 1922–23, being the thirty-first year of its existence. The College gives courses of instruction with the object of teaching missionaries how to care for their own health, and how to deal with the diseases of the people among whom they are working, when far from qualified medical aid. Altogether 752 students have passed through the College. Donations and subscriptions are requested to help carry on this useful work.

The ninety-second annual meeting of the British Medical Association will be held on July 18-26, 1924, at Bradford, under the presidency of Mr. J. Basil Hall, consulting surgeon to the Royal Infirmary, Bradford. The presidential address will be delivered on July 22. The following presidents of sections have been appointed:—Medicine: Prof. A. J. Hall; Surgery: Sir Cuthbert Wallace; Obstetrics and Gynæcology: Mr. J. S. Fairbairn; Pathology and Bacteriology: Prof. C. H. Browning; Neurology and Psychological Medicine: Dr. T. G. Stewart; Ophthalmology: Dr. A. M. Ramsay; Public Medicine and Industrial Diseases: Mr. H. Jones; Diseases of Children: Dr. L. Findlay; Laryngology and Otology: Dr. W. J. Horne; Orthopædics: Mr. R. C. Elmslie; Medical Sociology: Mr. A. Manknell; Dermatology: Dr. J. MacL. H. MacLeod. The honorary local general secretary is Dr. W. N. West Watson (Victor Lodge, Manningham, Bradford).

The Seismological Society of America has published a large Fault Map of the State of California (three sheets and a title-sheet) on the scale of 1 : 506,880, or close on one inch to eight miles. The topography is based on various official surveys, the hills being well brought out by a system of colour-shading. The sea-depths are shown by contours drawn at intervals of 100 fathoms. The known and probable faults, which mean so much in the moulding and instability of the continental edge, are marked by lines of various colours; these are broken where details are uncertain or inferred. A fault indicated as "active" is usually one along which an earthquake has occurred during historic time. The mind of the world has been once more riveted on the uncertainties of the Pacific ring, and this map, which must be mounted as one wall-sheet for its proper appreciation, will no doubt find a permanent place in colleges that respect geography. Prof. Bailey Willis has furnished a lucid description to accompany the sheets (Bull. Seism. Soc. America, vol. 13, No. 1, 1923).

A report by the Meteorological Department of the Government of India for 1922–23 has just been issued under the superintendence of Mr. J. H. Field, the officiating Director-General of Observatories. The policy of Indianisation has been adopted, and the personnel for the thirteen posts of meteorologists has changed from 10 Europeans and 3 Indians in 1919 to

3 Europeans and 10 Indians in March 1923. A study of upper air movements in India is said to be laying the foundation for types of forecasting not hitherto possible from surface observations. The whole system of warnings for storms and cyclones over the sea and on land throughout India is the duty of the headquarters staff, and all is now done from Simla. Considerable retrenchment has been made during the year, which has involved the partial stoppage of Bombay, Madras, and Calcutta Daily Weather Reports, the issue being suspended during the seasons of least rainfall. Shipping at sea is supplied with the latest information regarding the weather by wireless bulletins. Upper air research shows that at heights of 4 miles and upwards the cold weather winds of northern India often reach a strength of 100 miles per hour or more, while calms prevail at the surface. At Agra the westerly components of upper air, at a height of about 4 miles, prevailing from the middle of September to the middle of October, show a close relationship with the precipitation in north-west India in the winter following. Departmental observatories for the year consist of 5 first class, 185 third class, 23 fourth class, and 24 fifth class. Rainfall observations are received from 2926 stations.

Messrs. Hawksley and Sons, 83 Wigmore Street, W., have forwarded to us their catalogue of medico-diagnostic, physiological, anthropometrical, psychological, and chemical apparatus. Several forms and sizes of capillary pipettes for the accurate measurement of quantities from 0·005 c.c. to 1·0 c.c. are listed, as well as several types of hæmacytometers and hæmoglobinometers for the estimation of the number of corpuscles and amount of hæmoglobin in blood. Under blood analysis apparatus we find outfits for the estimation of calcium, urea, and sugar in the blood. Galton's finger-print outfit and whistle and many pieces of anthropometric and psychological apparatus are catalogued. Messrs. Hawksley are also agents for the microscopes and accessories of the Spencer Lens Co., New York.

In the "Fauna of British India" Series the further volumes which the editor, Sir Arthur E. Shipley, with the assistance of Dr. Hugh Scott and with the sanction of the Secretary of State for India, has arranged for are: volumes on Butterflies (Lycænidæ and Hesperiidæ) by Mr. N. D. Riley; on the Ixodidæ and Argasidæ by Prof. G. H. F. Nuttall and Mr. C. Warburton; on Leeches by Mr. W. A. Harding and Prof. J. Percy Moore; on the Curculionidæ by Dr. G. A. K. Marshall; on the Carabidæ by Mr. H. E. Andrewes; on the Meloidæ by Mr. K. G. Blair; on the Erotylidæ and Endomychidæ by Mr. G. J. Arrow; on the Culicidæ by Capt. P. J. Barraud, Major S. R. Christophers, and Mr. F. W. Edwards; on the Chrysomelidæ (subfamilies Chrysomelinæ and Halticinæ) by Mr. S. Maulik; on the Scolytidæ and Platypodidæ by Lt.-Col. Winn Sampson; together with a revised edition of Mammalia by Mr. Martin A. C. Hinton and Mr. R. I. Pocock, and of Birds (6 vols.) by Mr. E. C. Stuart Baker.

The latest catalogue (New Series, No. 10) of Messrs. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, should, we think, be very useful to librarians and others, it being a classified list of some 840 serials and transactions of scientific societies on sale by them. The catalogue is conveniently arranged under the headings: British Isles—Transactions of societies and other scientific periodicals; British Isles—Proceedings of local societies; Dominions and Colonies—scientific serials. etc.; United States of America—scientific serials, etc.; and foreign countries—scientific serials, etc.

Our Astronomical Column.

The January Shower of Meteors.—This display of meteors is of greater importance than is supposed. It sometimes furnishes a rather brilliant exhibition of a conspicuous character, being more brilliant than the average and traversing longer paths. The radiant point is situated at about 230° + 53° in the region barren of bright stars lying on the borders of the constellations Boötes, Draco, and Hercules.

The shower has occasionally been so abundant as to furnish one or two meteors per minute. In the evening hours, from the latitude of England, the radiant point is situated at a low altitude in the northern sky, and it is generally in the few hours preceding sunrise that the display attains its greatest strength. Unusually rich returns of these meteors were witnessed in the early evening hours of January 3, 1918 and 1922, and we may expect another plentiful exhibition of its meteors on the morning of January 4 next between about 4 and 6 a.m. The moon will not offer any obstruction on that date, as it will be 26 days old and visible as a very narrow crescent only.

Should the weather be clear on the morning of January 4, all the conditions are promising for a meteoric spectacle of very interesting character, and it will be important to observe it carefully through the night in order to determine the hourly number of meteors visible and the time when it reaches a maximum.

The Axis of Mars.—*Popular Astronomy* (November) contains an interesting study by Prof. W. H. Pickering of the position of the axis of Mars. He notes that the method used by Lowell of observing the polar caps is subject to a systematic error. The edge of the cap has a sensible diurnal shift: the white deposit melts on the noon side of the cap, and forms again on the opposite side. Accordingly a new determination was made, based on a large number of small well-defined markings spread over the disc. Incidentally the conclusion was reached that a large number of the Martian spots have a sensible annual shift, easily explicable on the view that they are vegetation phenomena. This, however, can be eliminated from the discussion. Prof. Pickering's final value for the obliquity of the Martian equator to its orbit is 24° 14′, a degree greater than Lowell's. He gives for the co-ordinates of the point to which the N. pole is directed—

$$\text{R.A.} = 20^h\ 58^m\ 6^s + 1{\cdot}56^s\ (t - 1918)$$
$$\text{N. Decl.} = 52°\ 12'\ 50'' + 12{\cdot}6''\ (t - 1918).$$

The equinox of the planet is shifted back 7·16° from 87·89° to 80·73°. This has the effect of increasing the Martian date by 14 days. The method employed seems to give this determination more weight than any other that is based on markings on the disc.

Research Items.

The Cave of Macpelah.—In the concluding issue for the year of *Ancient Egypt*, Sir Flinders Petrie discusses the probable position of the double cave below the Herodian monument which is described in the lately published "Hebron, le Haram el Khalil," by Père Vincent and Captain Mackay. Owing to the fanaticism of the present Arab population, the authors of this work were not allowed access to the subterranean parts. Our knowledge of these is derived from an account, written in A.D. 1136, of an examination of them in A.D. 1119 by the monks. Sir Flinders Petrie's conclusion is that the double cave probably lies to the S.E. rather than to the N.E. of the basilica-like chamber to which the monks penetrated. A point of interest in connexion with the superstructure is that while the internal proportions indicate the Jewish foot as the unit, those of the exterior conform to the Roman foot, the design being based on the fact that the two units can be worked together on a ratio of 10 : 11 in the length or 11·5 : 12·5 in the breadth.

Rock Paintings in Papua.—Dr. W. Mersh Strong has published in the December number of *Man* photographs and tracings of a number of rock paintings from the Central District of Papua. They were found on a prominent whitish rock, and were executed in a single monochrome red, apparently a preparation of iron oxide. The designs included a cassowary, a figure of a man, a scroll pattern, a double chevron with pendent lines, possibly a tortoise, a man's face, a crescent, and a hand. There is nothing to indicate their age except that they are covered with a slight film, probably of calcium carbonate derived from the trickling of water. The present natives have no knowledge as to who did them. Dr. Strong is of the opinion that the face design suggests the face *motif* of the Papuan Gulf, but points out that this culture has its centre some two or three hundred miles west of Port Moresby and scarcely comes within a hundred miles of that area. He also refers to the paintings of canoes and men in red monochrome seen by Seligman in the Marshall-Bennet Islands.

The Copper Eskimo.—Two further instalments of the Report of the Canadian Arctic Expedition 1913–1918 have just been issued; these are "The Physical Characteristics of the Copper Eskimo," by D. Jenness, and "The Osteology of the Western and Central Eskimo," by John Cameron, being parts B and C of volume xii. The measurements given by Mr. Jenness were, for the most part, taken at Coronation Gulf, where the expedition spent two years. Mr. Jenness concludes that there is strong support for Boas's view that Indian admixture in Alaska has increased the stature and produced a marked tendency towards brachycephaly; and that while the Copper Eskimo show more resemblance to the Eastern Eskimo than to the Alaskan, they differ from most other Eskimo in that the head is slightly longer and broader, although the cephalic index is virtually the same as among the pure-blooded tribes to the eastward. It is interesting to note that Mr. Jenness finds no evidence to support Dr. Stefansson's theory of European admixture among the Copper Eskimo. Of the features principally relied upon by Dr. Stefansson, Mr. Jenness holds that the proportion of face breadth to head breadth is illusory, and the blue or grey tinge of the eye is pathological in origin and common elsewhere.

Causal Organism of Potato Blackleg.—As the result of a study of twelve strains of the potato blackleg parasite, including the four "species" originally described as the cause of the disease, H. M. Jennison concludes, in a paper published in the Annals of the Missouri Botanical Garden, vol. x. No. 1, February 1923, that the blackleg disease of Irish potatoes in North America and Europe is caused by a Schizomycete which should bear the name *Bacillus atrosepticus* van Hall. The following names are to be considered only as synonyms: *Bacillus phytophthorus* Appel, *B. solanisaprus* Harrison, *B. melanogenes* Pethybridge and Murphy. The pathogen infects the stems and the tubers of the potato. Virulence of the parasite, as tested by artificial inoculation, appears to be dependent upon a rather delicate balance of temperature and water relations, and upon the sugar content of the tissues inoculated.

Cytology of Mutation.—Prof. R. R. Gates has an important paper in the *Annals of Botany*, vol. xxxvii. No. 148, October 1923, under the title "The Trisomic Mutations of Œnothera," in which he describes the occurrence in the F_1 generation of the cross *Œnothera rubricalyx* × *Œ. Hewettii* of a mutant with fifteen chromosomes, and discusses in connexion therewith the whole question of the chromosome mechanism associated with such types of mutant. In Œnothera, relatively few mutants are found with fourteen chromosomes; these may be accounted for in terms either of crossing over or of double "non-disjunction." "Non-disjunction" has been called in to explain the existence of the relatively frequent trisomic mutations (with 15 or 16 chromosomes). It is assumed that on segregation two chromosomes of a pair, instead of separating to different gametes, both go into one cell; thus in a pollen tetrad two pollen grains will be found with eight chromosomes each instead of seven. When, as in the mutation now described by Prof. Gates, two precisely similar mutants appear in a small culture, it would seem probable that both such pollen grains have functioned, so that the male parent is responsible for the extra pair of chromosomes. Inevitably in discussing such a problem the question arises as to what extent the seven pairs of chromosomes in Œnothera may be regarded as individually distinct. Prof. Gates discusses the question in a tentative manner, directing attention to recent statements by Hance (1918) and Van Overeem (1922), who conclude that these seven pairs are distinct and form a graded series. Prof. Gates is evidently of opinion that this conclusion is not yet sufficiently soundly based upon observation and experiment, but that the cytological complexities of the problem well deserve further exploration.

Distribution of Herring Shoals.—The report of the Dove Marine Laboratory, Cullercoats, for 1922–23 contains an interesting paper by Mr. B. Storrow on the distribution of herring shoals. Evidence is given in favour of the view that the failure of the industry in 1921 was due, in part, to a migration of young North Sea herrings in the preceding winter. Late in 1920 these fish divided into two sections, one of which migrated northwards towards the Orkneys and Shetland, and the other southwards. The northern group thereby passed into an area favourable to growth, and grew rapidly. The southern section grew much less rapidly. If this be so, the herring industry in any particular locality should depend upon whether the herring caught are migrants from a region of rapid or of slow growth, rather than upon the existence of a particular year class. The author is inclined to the view that migrations, which may in some cases depend upon the "activity" of Atlantic

water, prohibit the existence of different herring races in the North Sea.

EUCALYPTUS OILS AS GERMICIDES.—Messrs. A. R. Penfold and R. Grant give an account of an investigation of the germicidal values, determined as Rideal-Walker carbolic acid coefficients, of the principal commercial eucalyptus oils and of their active constituents (Journ. and Proc. Roy. Soc. of N.S. Wales, vol. lvii., 1923, p. 80). Standard suspensions of 1 per cent. of the crude oils and their pure constituents were made in 7½ per cent. resin soap solution. Of the oils of ten species of Eucalyptus, that of *E. radiata* was the strongest and gave a coefficient of 10-12, the active principle being piperitol. Of active principles, australol, geraniol, citral, and piperitol gave coefficients of 22·5, 21, 19·5, and 13 respectively. The interesting observation is made that a lower coefficient is given by the dilution (with water) of a concentrated preparation than by a dilute preparation of the same strength, probably because the dilution of a concentrated emulsion upsets the emulsion.

RED DISCOLORATION ON DRIED SALTED FISH.—The condition known as "pink" is one to which dried salted fish is liable, and is characterised by the appearance of pink patches on the surface. It is dealt with in Special Report No. 18 of the Food Investigation Board by Dr. P. C. Cloake. These pink patches are caused by the growth of chromogenic micro-organisms of at least two species—one a red sarcina, the other a curiously polymorphic form which may be a bacillus. These organisms may be cultivated on such media as salted fish agar, provided they contain a high percentage of salt, *e.g.* 15 per cent., at a temperature of 24° C. The source of these organisms has been traced to the salt used in curing when this is of marine origin; rock salt seems to be free from them. Sterilisation of the salt at 120° C. for 30 minutes suffices to destroy the organisms.

A SUGGESTED INDICATOR FOR PETROLEUM.—In the Journal of the Royal Society of Western Australia, vol. 9, p. 8 (1923), A. Farquharson describes an occurrence of the hydrocarbon impsonite, infilling the vesicles of a basalt that underlies a limestone variously regarded as of Cambrian or Lower Carboniferous age. Specimens have been collected from various points in the Ord Valley near Kimberley, West Australia, and these were sent to the office of the Geological Survey in the first instance as possibly oil-bearing shales. The author points out that the occurrence is of sufficient magnitude to have a bearing on the search for petroleum in the district. We need not share his view (p. 17) that oil would be unlikely to occur if the rocks were of Cambrian age, since seepage from a distance is always possible, and the highly vesicular character of the basalt may have provided a favourable storehouse on the way. As E. H. Cunningham Craig remarks, migrating petroleum will make its appearance in "the most porous rock available."

CLIMATIC CHANGES AND WEATHER NORMALS.—The U.S. *Monthly Weather Review* for August contains an article by Prof. C. F. Marvin, Chief of the U.S. Weather Bureau, on the above subject. The discussion is introduced by a question, "Is the climate changing?" and justifies the answer of "Yes" or "No" to this inquiry. Geological records are said to leave no question as to the great changes the vast lapse of time has occasioned in the past, while there is said to be no conclusive evidence of notable permanent changes during thousands of years of human history. The author believes that long-time fluctuations of climatic conditions have occurred, and that minor surgings of the seasons to and fro take place for such periods as 50 to 100 years. Reference is made to the somewhat general deep-seated conviction that, to many, weather conditions at the present time differ from corresponding conditions within their memory. The prime object of the discussion is to establish a method of completing a broken record of observations, say of temperature or rainfall, so as to lengthen out to the utmost a series of observations and thus to secure long-period normals of observations to aid in obtaining proof of secular changes if such are obtainable. A method is suggested for completing the individual values for missing years which is practically a system of drawing lots from the values of all the years for which observations exist, and so on for all the years for which means are required. This system scarcely seems likely to commend itself to all workers. Considerable importance is attached by the author to the use of accumulated sums of departures from a normal base and exhibiting the same as a graph.

PHOTOELECTRIC CELLS FOR MEASUREMENTS OF TIME.—In the *Comptes rendus* of the Paris Academy of Sciences, November 5, 1923, Messrs. G. Ferrie, R. Jouart, and K. Mesny describe methods employed to amplify the current from a photoelectric cell, so that the amplified current can be used to record the passage of a pendulum through a certain point of its path. The anode of the photoelectric cell was joined to the grid of a special triode valve, and the filament of the valve to the positive of a battery, the negative of which was connected to the deposit of alkali metal in the cell; a constant high potential difference was applied between the anode plate and the filament of the valve. When the cell was illuminated, the grid was charged negatively, and the current of the valve was diminished. In this way a variation of current, 10,000 times as great as the original photoelectric current, can be obtained; and, by attaching to a pendulum a screen, provided with a slit, through which light from an electric lamp can pass, measurements of the time of vibration can be made with considerable accuracy. With a more complicated arrangement of valves, an amplification of the order 10^6 was obtained and it was possible to determine the period of the pendulum within one-thousandth of a second. The authors hope to be able to adapt the method for recording the passage of stars across the central line of a meridian telescope.

VELOCITY DISTRIBUTION OF ELECTRONS FROM INCANDESCENT OXIDES.—The velocity distribution of the electrons ejected from incandescent substances has been investigated by the integral method, not attempting to separate out the electrons moving at or near a definite velocity, but deducing the distribution law from observations which included all the different velocities present; Richardson used also the differential method. All the observers have found that Maxwell's probability law for the distribution of the velocities is correct in the case only of clean metal surfaces. In the *Zeitschrift für Physik*, November 15, 1923, Herr M. Rössiger describes experiments, using the differential method, in which the electrons pass through a longitudinal slit, parallel to the axis of the cylindrical anode; this is coaxial with a straight, incandescent platinum wire which forms the cathode and is coated with oxides of calcium, barium, or strontium. There is an outer cylinder, coaxial with the first, and electrically connected with

it; in this is a slit, parallel to that in the surface of the inner cylinder, while outside this slit, and insulated from the cylinder, is a collecting plate, which receives the electrons which pass through both slits. The inner cylinder can be rotated about its axis; so that the angle ϕ between the planes passing through either slit and the cathode wire can be varied, and measured by means of a reflecting mirror. A solenoid is wound round the cylindrical glass containing vessel, so that a magnetic field can be produced in the direction of the axis of the cylinders, deflecting electrons with a certain velocity which pass through the first slit, so that they pass through the second when ϕ has the correct value. Maxwell's law is still found to hold.

Magnetic Survey of the Balkans.—Heft 10, Bd. 131, Abt. IIa, Math. Nat. Kl. of the Sitzungsberichte of the Vienna Akademie der Wissenschaften contains a paper by Mr. A. Schedler, which gives the results of a magnetic survey carried out during 1918 in the Balkans. Results are given for 27 stations, varying in latitude from 44° 49′ to 40° 55′ N., and in longitude from 18° 32′ to 21° 55′ E. Attached to the paper are six charts. The first and the last indicate the geographical positions of the stations, and the geological features of a magnetically disturbed region. The four intermediate charts give curves of equal values of magnetic declination, inclination, horizontal force, and total force respectively for the epoch January 1, 1918. Through an oversight, the values of the force are printed as angles in the charts. For example, 0·4444 C.G.S. is printed as 44° 44′. It is interesting to note that the dip observations were taken with an English dip circle, Dover No. 1.

Inverted Flight in Aeroplanes.—A paper of considerable interest to practical aviators, as well as to workers in the dynamics of aeroplane flight, was read recently before the Royal Aeronautical Society by Squadron Leader R. M. Hill. The paper is entitled "The Manœuvres of Inverted Flight," and is based upon extensive experimental flights executed by Mr. Hill and others. The object of the experiments was threefold. The immediate aim was to examine the causes of fatal accidents that often occur in aerobatics on an unstable aeroplane, when the aeroplane assumes an inverted position and the pilot fails to right the machine. Subsidiary aims were to find the magnitudes of the loads in inverted flight, and to examine the behaviour in inverted flight of machines with different stability characteristics. An account is given of the ways in which inverted flight can be obtained, namely, by means of the half loop and the half roll, and details of the manœuvres are given for particular aeroplanes, such as the Sopwith "Camel," the "Camel" modified so as to increase its longitudinal stability, the "Snipe," the "Bat Bantam," and the S.E.5A. The use of the controls in inverted flight and the return to normal flight are similarly discussed. Mr. Hill considers the belting arrangements to be of supreme importance, especially in unstable fighting machines; pilots often fail to use the controls because they cannot reach them. Steady inverted flight is possible on all types of machines investigated; but whereas the longitudinally stable machine tends to right itself, the longitudinally unstable machine has no such self-righting properties: there is, however, no real difficulty in recovering from the inverted flight. The longitudinally unstable machine is also liable to get into an inverted spin, but here again the pilot can recover if he knows the use of the controls in such positions. Inverted loops were also investigated. Mr. Hill suggests that "the best compromise between safety and extreme manœuvrability is to be found in an aeroplane which, though preferably stable throughout the major part of its range of flying speeds with elevators free, must definitely be stable with them fixed."

Silicate of Soda for the Treatment of Concrete Roads.—Silicate of soda is now being more and more used in Great Britain for the surface treatment of concrete, following on the extensive and very satisfactory experience recorded in America. In fact, new uses for silica of soda are being found almost every day, and this material looks like rivalling sulphuric acid, soap, or soda ash as a ready test, according to the amount consumed, for the civilisation of a community. The chemical reactions that result from the application of a dilute solution of silicate of soda to concrete, say the surface of a road, are very complicated, but seem to include the combination of the silicate with the free hydrated lime liberated in the setting of cement to give a lime silicate, which forms a hard compound. At any rate, the nett result is the formation of an intensely hard outer skin—in which all the pores have been completely filled up—strongly resistant to abrasion and dusting, and largely waterproof. It is essential, however, that the silicate of soda be sprayed over the road in the form of a very dilute solution, say 1 of the liquid neutral silicate to 4 of water, whilst the silicate of soda must be prepared for the specific purpose, with a fairly high ratio of silicate to soda. As is well known, very many grades are supplied, from a low-ratio product containing 1·60 molecules silica to 1·00 molecules soda (Na_2O) to a very high-ratio grade with over 4·0 molecules silica. The right brand to use is a matter of experience and research on the part of the firms supplying the product, but the results, under proper conditions, are remarkable, and constitute a factor of national importance in the upkeep of roads.

Tests on Boiler Material.—The annual memorandum by Mr. C. E. Stromeyer, Chief Engineer to the Manchester Steam Users' Association, covering the year 1922, contains several interesting matters. Tests have been made on the material of some old wrought-iron boilers, one of which was sixty-nine years old, and a comparison with the tests of the original material shows that wrought iron does not lose tenacity appreciably with age. The furnace plates show a reduction of ductility, but not of tenacity. Mr. Stromeyer again directs attention to the effect of nitrogen on mild steel, and urges that the effect of a high proportion of this element, such as is found in Bessemer steel, requires more thorough investigation. A table of failures of mild-steel plates, bolts, stays, and rivets is given, 22 in number, and in every case the sum of $5N+P$ is greater than 0·08 per cent., the upper limit previously fixed by the author. A case for inquiry has been made out, and it is to be desired that analyses for nitrogen should be made more frequently, until its alleged harmfulness has been confirmed or disproved. The tests on riveted joints in old boilers show that the strength of a double-riveted seam in a boiler is greater than that found when the seam is cut out and the joint tested in a machine, so that the engineering practice of crediting the joints with their full strength is justified. An interesting section on dished and flat-end plates of boilers deals with the behaviour of cracks, which in some cases do not spread, but relieve the stress, so that some boilers mentioned worked for years in a cracked condition. This is traced to a very finely laminated structure in the outer layers of the plates.

The Jubilee Celebrations of the French Physical Society.

It was in 1873 that the Société Française de Physique came into being, and the first volume of the Proceedings of the Society contains a report by Lissajous on the preliminary steps that were taken. The statutes include one by which any discussion "étrangère à la physique" is prohibited. Whether the French physicist of fifty years ago was a keen politician we do not know, but it seems to have been desirable to provide against extraneous matters more rigorously than is our wont in Great Britain.

A glance at the first list of members reveals a number of very well-known names, such as the Becquerels, Berthelot, Bouty, Cornu, Jamin, Joubert, Koenig, Lippmann, Lissajous, Mascart, Sainte-Claire Deville, and Violle. The first president was Fizeau, and the following eight successive presidents were Bertin, Jamin, Quet, E. Becquerel, Blavier, Berthelot, Mascart, and Cornu. The first honorary member was the elder Becquerel. In 1876 there were five honorary members, including Regnault and Sir William Thomson; and in 1878 the names of Fizeau and Joule were added.

In the early part of this month, the founding of the Society was celebrated by a number of meetings. Apart from these there has been the Exhibition, which has hitherto been held by the Society at Easter, but has this year been combined with a Wireless Exhibition. It has been on an unusually large scale, as may be realised when it is said that the Grand Palais in the Champs Élysées, in which the annual Automobile Show is held, was used for the purpose. The Exhibition was excellent from many points of view, and was characterised by many demonstrations, more or less popular, which were very attractive.

The anniversary lectures were given at the Sorbonne, the first on Saturday, December 8, by Col. Robert, on the relations of physical and technical aeronautics.

On Monday morning, December 10, an attraction of another kind presented itself in the general meeting of the International Union of Physics. The chair was taken by M. Brillouin with Prof. H. Abraham as general secretary. The business was largely formal, the main item being the adoption of the statutes. After some discussion as to whether the value of the franc for the contributing countries should be taken in the French or Swiss currency, the former was adopted, notwithstanding the reduction in the contributions by so doing. The date of the next meeting of the Union was fixed for the year 1925, the normal three years' interval being reduced, and the question of an international congress will then be decided. A somewhat pious resolution was adopted on the desirability of authors supplying abstracts to their papers, such abstracts being left in the hands of the editor of the journal concerned for final revision. The meeting was followed by a luncheon.

On Monday evening a lecture was given by Prof. H. A. Lorentz on the old and new mechanics. The motion resulting from the impact of two balls was considered, and generalised equations were obtained which were applicable to two observers in relative motion. This was followed by the gravitational deflexion of light, and a discussion of the quantum theory and kindred subjects. The address was a model of lucidity, and at its conclusion Prof. Lorentz received quite an ovation from a crowded audience.

On Tuesday, December 11, Lord Rayleigh gave an interesting account of his investigations on iridescent colours in Nature. He dealt successively with the colours observed in light reflected from potassium chlorate crystals, mother-of-pearl, Labrador felspar, and scarabee. This work was described recently in a series of papers read before the Royal Society.

At the conclusion of the lecture Prof. Volterra presented, on the behalf of the Accademia dei Lincei, two volumes of the collected works of Volta. Other volumes are in preparation.

Wednesday, December 12, was marked by a banquet at which the delegates were royally entertained. The chair was occupied by the Under Secretary of State for Public Instruction. M. Picard (president of the Société Française de Physique) welcomed the foreign delegates, and responses were made by Prof. Volterra, Prof. Lorentz, Lord Rayleigh, Prof. Stormer, and Prof. Knudsen.

The culminating point in the celebrations came on Thursday afternoon, when the chair was taken by the President of the Republic in the large amphitheatre of the Sorbonne. There were also present the Ministers of Commerce, of Public Instruction, and of Public Works. After speeches by M. Picard and M. Brylinski (president of the French Electrotechnical Committee), Prof. Lorentz presented the addresses which had been brought by the delegates. These were numerous, and, in the alphabetical order of the countries from which they came, were from the following societies: L'Académie Royale de Belgique, La Société Scientifique de Bruxelles, L'Académie Royale de Danemark, L'Institut d'Égypte, L'Académie des Sciences de Madrid, Bureau of Standards, Carnegie Institution of Washington, L'Académie des Sciences de Finland, Royal Society, Royal Institution, Physical Society of London, Röntgen Society, Accademia dei Lincei, Accademia di Torino, La Section de Physique du Conseil National de Recherches du Japon, Le Ministère de l'Instruction Publique du Grand Duché de Luxembourg, La Société de Physique de Christiania, L'Académie Royale des Sciences d'Amsterdam, La Société Hollandaise des Sciences de Haarlem, L'Académie de Cracovie, La Société Polonaise de Physique, La Société Suisse de Physique, La Société de Physique et d'Histoire Naturelle de Genève, La Société Zurichoise de Physique et l'École Polytechnique fédérale de l'Université de Zurich, L'Union des Mathématiciens et des Physiciens tchecoslovaques à Prague.

After this part of the ceremony came a speech by M. Bérard (Minister of Public Instruction), followed by remarks by the President of the Republic. The latter with his ministers then withdrew, and we settled down to a discourse by Prof. C. Fabry on the domain of radiations. The programme was interspersed throughout by a selection of music rendered by the celebrated band of the Garde Républicaine.

The magnificent amphitheatre of the Sorbonne, in which these proceedings were held, seats about 3000 people, and gave rise to some reflections, possibly not only on the part of the present writer. Where is such a theatre to be found among our educational institutions in London? Unfortunately, nowhere; and if we had such a theatre, would an audience of, say, 2500 people come on such an occasion, and listen to an address (unillustrated) on the difficulties experienced in exploring the field of radiation, from the longest waves, as used in wireless telegraphy, to the shortest, as shown by X-rays? We doubt it, even if the Prince of Wales were present. The value of science is obviously recognised more fully in Paris than in London.

Lectures by Prof. Störmer on the aurora borealis on Friday, December 14, and by Prof. Knudsen on the mechanism of evaporation and condensation, on Saturday, brought to a close these very interesting and very successful celebrations.

Virus Diseases of Plants.

AN interesting discussion upon "Virus Diseases of Plants" was held during the meeting of the British Association at Liverpool between the Sections of Botany and Agriculture. These obscure maladies, which are of great economic importance, affect a great variety of cultivated plants and have lately received much attention from plant pathologists. Formerly these diseases were attributed to general physiological degradation, notably in the potato, but since they have been shown to be markedly infectious, they are usually considered to be caused by organisms of ultramicroscopic size, which are disseminated largely by means of insects.

The discussion was opened by Dr. Paul Murphy, who first described the symptoms of these diseases in general and compared them briefly with certain diseases of animals of somewhat similar type. He then dealt specifically with the "leaf-roll" and "mosaic" diseases of potatoes, both of which cause enormous losses in yield. In discussing "leaf-roll" of potatoes, Dr. Murphy maintained that the abnormal accumulation of starch in the leaves, which led to rolling, preceded the degeneration of the phloem, which is also a marked symptom of this disease. In potato "mosaic," characterised first by a mottling of the foliage and later by marked degradation of the whole plant, he stated that this disease sometimes masked other "virus" diseases of the potato such as "stipple-streak" and "crinkle." He had also demonstrated that certain varieties might act as "carriers" of this disease, in which the symptoms remained dormant, although infection could still be spread from these plants. As instancing the rapidity with which degeneration caused by such diseases might occur, Dr. Murphy said that on a farm at Ottawa potatoes had been grown healthily for seventeen years, but that, after this period, marked degeneration set in during the course of a single season, which had affected all potatoes subsequently grown on that farm. He considered, however, that there still remained a certain reduction in yield attributable to non-pathogenic causes when the same healthy stock was grown in different but apparently suitable localities.

Prof. H. M. Quanjer, of Wageningen, Holland, who has made a special study of these diseases in the potato, then gave an account of his own researches on these maladies. In regard to "leaf-roll" he combated the view of Dr. Murphy that the seat of the disturbance lay in the abnormal accumulation of starch in the leaves, maintaining that the primary effect of disease was the necrosis of the phloem consequent upon the entry of the "virus" through insect agency. He pointed out that infection by aphides during May and June first resulted in rolling of the upper leaves during August. Prof. Quanjer claimed that the real seat of these "virus" diseases was the phloem, and suggested therefore that they should be called "phloem diseases" rather than "virus" diseases, although he admitted there was no visible degeneration of the phloem in "mosaic" diseases. In this connexion also it must be conceded that there are other diseases of phloem tissues which do not fall into the category of "virus" diseases. Prof. Quanjer emphasised the rôle played by insects, especially aphides, in the dissemination of these diseases, but pointed out that in some "mosaic" diseases transmission was possible through mechanical abrasion of the leaf hairs.

Dr. W. B. Brierley exhibited lantern slides which showed in a striking manner, by reference to American statistics, the losses caused by these diseases in crop plants. With regard to sugar-cane "mosaic," he stated that varieties resistant to the disease had recently been discovered which would probably prove the salvation of the cane industry in certain districts.

Mr. T. Whitehead classified "virus" plant diseases into four categories, of which the following are examples:

(1) Infectious chlorosis, which is transmissible only by grafting.

(2) Spike disease of the sandal-wood tree, in which there is neither abnormal starch accumulation nor phloem necrosis.

(3) Leaf-roll of potatoes, in which abnormal starch accumulation accompanies phloem necrosis. This disease is transmissible by insects, but not by expressed sap alone.

(4) Potato mosaic, in which there is neither accumulation of starch nor phloem necrosis, although the sugar content may be unusually high.

This disease is transmissible by the sap alone, without insect agency. Mr. Whitehead appealed for more accurate methods in diagnosing this group of diseases, and gave striking evidence for the transmission of potato "leaf-roll" through the soil. He suggested that these diseases could be best controlled by raising resistant varieties and by establishing special beds of potatoes for seed purposes, which could be rogued effectively and lifted early.

Mr. Holmes Smith expressed the view that leaf-roll was by far the most serious of the "virus" diseases of the potato in this country. Unfortunately manurial treatment had no effect upon it, although this was somewhat beneficial in potato mosaic.

Dr. R. N. Salaman pointed out that although this year he had taken the trouble to spray his seedling potatoes, planted in old garden soil, with nicotine at frequent intervals in order to control aphides, infection by mosaic and leaf-roll had been more serious than ever before, although seedlings planted in remote plots in other crops had remained healthy. *Solanum nigrum* appeared to be of no importance as a "carrier" of these diseases. Dr. Salaman expressed the view that "virus" diseases of the potato were probably not congenital, and that susceptibility to leaf-roll was transmitted independently of susceptibility to mosaic disease.

F. T. BROOKS.

Australian Railway Development: a Study in Political Geography.

MR. O. H. T. RISHBETH read a paper on this subject to Section E (Geography) of the British Association at Liverpool. Railway systems typify the humanised as opposed to the purely physical environment, and in so far as they reflect the higher social and political mentality of the people, contribute most useful data for the human geographer. In Europe the system of national states, with their semi-geographical basis, was evolved before the railway era. The railway systems superimposed on a well-defined national background share the intense individualisation of the continent. Europeans brought to Australia this tradition of individualism and exclusiveness.

Mr. Rishbeth maintained that Australia is a clear-cut geographical unity and that its interstate bound-

aries are mathematical and artificial: with one or two exceptions they have no geographical meaning. The early settlements around the island-continent were separated by long stretches of inhospitable coast and still more difficult interior. From these various centres the human settlement developed on old-world lines. This is expressed in the various state railway systems, each planned without reference to those of adjoining states.

The geographical and economic unity of the island was overlooked until a much later date, but the commonwealth feeling or spirit is now making rapid headway and is reflected in the new and newly planned railway lines. These lines are projected to bind together and not to separate the various states. All major Australian railway schemes are essentially commonwealth propositions in that they involve the interests of more than one state. A sketch map was shown to indicate the economic areas, independent of political divisions, which may be regarded as the hinterlands of different stretches of sea coast. On this map it is possible to forecast, with tolerable certainty, the main outlines of the completed Australian railway system. Briefly, this entails an outer ring of which the elements already exist; an inner circle; fragments of a radial system cutting across both circles and joining hinterlands with their appropriate ports; certain overland lines from north to south and east to west. These systems when fully built will unify the continent and overrule the artificiality of the original states.

Structure of Greenland.

We have recently received, though the work is dated 1920, volume 53 of the "Neue Denkschriften der Schweizerischen Naturforschenden Gesellschaft,"[1] containing an account of the Swiss trans-Greenland Expedition of 1912–13. Between southern Greenland at about lat. 64°, where the country was crossed by Nansen in 1888, and Peary's routes of 1892–95 through 80° N., the interior of Greenland remained unknown for an interval of more than 1000 miles. In order to determine the structure along one line through this gap a Swiss expedition under Prof. de Quervain in 1912 traversed Greenland from the western coast in lat. 69° 46′ opposite Disko to the eastern coast in lat. 66°. The journey on the inland ice was begun on June 20. The summit of the ice-cap was crossed on July 8, and its eastern margin was reached on July 21. The party, with dog-drawn sledges, averaged 22 kilometres a day. Meanwhile the western party under Prof. Mercanton investigated the open country on the western edge of the ice-cap to the east of Disko Island.

The new traverse of Greenland confirms the general accuracy of Nansen's profile, though, as he crossed the country where the ice-cap is narrower but rises to a greater height, his gradients were steeper than those found by the Swiss party. Doubt is thrown as to the distance inland reached by von Nordenskjöld in 1883. The expedition, however, supports his view that cryoconite consists in part of meteoritic material. Nordenskjöld's conclusion has generally been rejected and the material explained as dust blown on to the ice from the nearest rocks. Part of the cryoconite collected by the Swiss expedition is regarded as derived from local diorite, but it contains spherules of magnetite which Prof. Mercanton regards as possibly of extra-terrestrial origin. In this view he supports the conclusions of Wulfing and of Swinne (1919). In the absence, however, of proved nickel, the meteoritic origin of the magnetite may still be regarded as open to doubt.

The western party made careful measurements of the ice movements, and found it to vary from less than a centimetre a day on the ice front to 2½ metres. It is shown that the bare land in west-central Greenland was once covered by the ice-sheet, and Prof. Mercanton supports the view that, with the exception of some of the high southern mountains, the whole of Greenland was once buried under an ice-cap. His account and photographs show the powerful disruptive effect of frost on bare rocks in the neighbourhood of ice. The larger part of the volume is occupied by the meteorological observations and results, including the records of some pilot-balloons.

The last chapter describes the collection of Eskimo skulls, and its author, Dr. Hoessly, rejects the view that the Eskimo reached Greenland from Europe across the Faroes and Iceland; he regards the Eskimo as the most primitive section of the Mongolian race. The volume is well illustrated by four plates of maps and sections, nine plates, and numerous figures in the text.

[1] "Neue Denkschriften der Schweizerischen Naturforschenden Gesellschaft" (Nouveaux Mémoires de la Société Helvétique des Sciences Naturelles) Band 53. Pp. xx + 402 + 54. (Basel, Genf und Lyon: Georg und Co., 1920.)

Building Materials made of Waste Materials.[1]

By Prof. A. P. Laurie.

We have in Great Britain large accumulations of blast furnace slag, of cinders, and clinker, and in the neighbourhood of Edinburgh of burnt shale, the residue from the stills of the oil industry. There are three ways in which these materials can be utilised—for the production of bricks, for the production of cement, and as aggregate mixed with Portland cement or plaster of Paris. The general method adopted for the production of bricks is known as the sand lime process. Briefly, this process consists of mixing the aggregate with a certain proportion of lime and water, squeezing it into a brick under a pressure of some two hundred tons to the area of the brick and then steaming under high pressure or in open steaming chambers. Bricks are now being manufactured by this process from sand, blast furnace slag, granulated by being run while hot into water, clinker, town refuse, slate dust, and burnt shale.

Cement is being manufactured by two of the Scottish steel companies from blast furnace slag granulated, mixed with lime, and then raised to a high temperature so as to form a clinker in the same way as ordinary Portland cement was manufactured. This cement, known in Germany as iron cement, can be sold in this condition, or can be finally ground with a mixture of a certain proportion of raw blast furnace slag.

The uses of these materials as an aggregate opens the question of how far it is possible to reduce the content of Portland cement and, at the same time, get sufficient strength for building purposes. The objection to the usual building slab made of cement is that, in order to be able to remove it from the machine as soon as made, the content of water has to be kept low and, consequently, the crushing strength of the finished slab is also low. Two interesting methods of getting over this difficulty are the Crozite method, in which the cement bricks were sliced off from the bottom of a column of cement and aggregate, and the method used by the Triangular Construction Company, in which a heavy compression is put upon the bottom and top of the slab at the

[1] Substance of a lecture delivered at the Royal Academy of Arts, London, on Wednesday, November 21.

moment of completion. It has been possible in the case of the slabs made by the Triangular Construction Company to reduce the amount of cement to one to twelve of aggregate, and the manufacture of cement bricks by the Crozite process is being carried on in a large scale in America.

Many waste products such as sawdust, disintegrated wood, and ordinary cheap aggregates such as clinker can be utilised in slabs made from plaster of Paris. There are large and easily available deposits of gypsum in Great Britain, but the industry has never been developed on the enormous scale found in America, where all kinds of materials required by the builder have been turned out made from plaster of Paris as the cement.

University and Educational Intelligence.

THE *University Bulletin* issued by the Association of University Teachers has hitherto been confined mainly to a record of the activities of the Association, which have been concerned largely with questions of remuneration and other conditions of tenure of university posts. In the November issue an effort is made to widen its circle of readers. Lord Gorell contributes an article dealing with three subjects: (1) expected developments of the functions of the Teachers' Registration Council with the view of the establishment of teaching as one of the unified learned professions; (2) the financial needs of universities; and (3) the projected Imperial Education Bureau. Prof. Arthur Thomson's thoughtful and arresting essay on the essentials of education deserves a wider circulation than the *Bulletin* can hope to give it. Here is a biologist dealing with the ignorance of young Scotland as faithfully as Prof. Burnet in his Romanes lecture dealt with the same subject from the point of view of the humanist. Over the familiar initials M. E. S. appears a plea for large capital grants to universities as recommended by the Royal Commission of 1870 on Scientific Instruction and the Advancement of Science. Prof. Sandbach tells of a committee having been appointed by the A.U.T. to consider and report on the subject of co-operation between libraries, possibly on the lines of the German central information bureau and general card catalogue, for the benefit of research workers in Great Britain and Ireland. There is also a contribution from Melbourne on the perils of inbreeding and localism in universities in the Overseas Dominions.

THE North of Scotland and the Edinburgh and East of Scotland Colleges of Agriculture append to their calendars for 1923–24 lists of appointments gained by their students. They illustrate the Scottish propensity, referred to in Mr. Rudyard Kipling's recent rectorial address, for "raiding the world in all departments of life—and government." The lists include posts in England (53), Canada, the United States, South America, the West Indies, Australia, New Zealand, South, West, East, and Central Africa, the Sudan, Egypt, Cyprus, Hungary, India, Burma, Ceylon, Straits Settlements, Malay States, Java, Sumatra, Borneo, Fiji, and Hawaii: only 60 out of the 280 were in Scotland. The director of studies of the North of Scotland College reports that in 1922–23 a record number of students (27) obtained the degree in agriculture. Both colleges do a large amount of "county extension" work in addition to the instruction and research carried on at their headquarters and at college and experimental stations. The northern college report records 67,096 attendances and 2929 classes and lecture meetings and 11,840 visits to farms and crofts for instruction and advice. A scheme of rural science to be taught in conjunction with school gardening was introduced into several schools and proved efficacious "in creating an interest in school gardening which is lacking at present."

RHODES Scholars in residence at Oxford in 1922–23 numbered 273, namely, 125 from the British Empire and 148 from the United States. Of these, 57 were taking natural science and medicine, 10 economics, and 6 mathematics. Sixty-eight Rhodes scholars were successful in the final honour schools examinations, namely, first class 14 (United States 8, Canada 2, Australia 2, New Zealand 1, South Africa 1); second class 31 (United States 16, others 15); third and fourth classes 23 (United States 11, others 12). The Ph.D. degree was awarded to 7 (all from the United States), the B.Sc. or B.Litt. to 17, and the B.C.L. to 18. Among other academic distinctions obtained by Rhodes scholars may be mentioned the Christopher Welch scholarship in biology and the James Hall Foundation essay prize, both won by Americans, the Francis Gotch memorial prize won by a scholar from New Brunswick, the David Syme research prize (Melbourne) won by a scholar from Victoria, the Bourse des Œuvres françaises à l'étranger (tenable for one year in a university in France) awarded to a New South Wales scholar, two demonstratorships and a tutorial fellowship at Oxford awarded to two Australians and a South African, and a Rockefeller Medical research fellowship, tenable in the United States, to which an Australian scholar was elected. In athletics distinctions were won by 11 scholars from the United States, 10 from Australasia, 6 from Canada, and 4 from South Africa.

A NOTABLE citizen of Bolton, Lancashire, Mr. J. P. Thomasson, made known to the School Board of the Borough in 1876 his intention to allot the sum of 750*l.* annually for a period of ten years, in order to assist scholars from the elementary schools to proceed to higher schools before becoming pupil teachers. His purpose was to secure a body of teachers in elementary schools efficiently educated and properly trained for their duties. The School Board felt that the full benefit to be derived from the scholarships would not be realised if they were restricted to those entering upon the profession of teacher, and Mr. Thomasson consented to enlarge the scope of the scheme so as to encourage pupils from the elementary schools to continue their education at higher schools and to encourage suitable pupils to become teachers. The scheme provided fees, books, railway fares, and a grant towards maintenance. Mr. Thomasson died in 1904, and Mrs. Thomasson intimated her willingness to continue the benefaction for a further period. Meantime the School Board ceased to act and the Town Council became the Education Authority. The scheme was enlarged in its scope, and provision was made for scholarships for boys and girls between 16 and 17 years of age who had been in attendance at secondary schools in Bolton to continue their education in such schools, for leaving scholarships of the annual value of 150*l.* tenable for three years at a university and for a post-graduate scholarship at a foreign university of the annual value of 200*l.* tenable for two years. The scheme has now come to an end. During the 46 years of its existence under varying conditions there have been awarded 122 major exhibitions, 427 minor scholarships, 36 scholarships in respect of continued education at secondary schools, 18 university scholarships, and one post-graduate scholarship. The total sum received from Mr. and Mrs. Thomasson amounts to 26,438*l.*, and the examination expenses, etc., to only 1718*l.* during the whole period, testifying to the fact that the scheme has been most economically administered.

Societies and Academies.

LONDON.

Geological Society, December 5.—Prof. A. C. Seward, president; and, afterwards, Dr. G. T. Prior, in the chair.—The following communications were read: C. W. **Osman**: The geology of the northern border of Dartmoor, between Whiddon Down and Butterdon Down. The Lower Carboniferous rocks may be divided into a Lower Aluminous and a Calcareous Series. The latter commences with grey shales above the Lower Aluminous series, without any physical feature, and contains a volcanic band, generally in a fragmentary condition, mixed with ash, slate, and other fragments, and impregnated with chert; but, at East Underdown, the rock is more solid, and is a quartzless keratophyre. The corresponding mixed igneous rocks of the north-western Dartmoor border, which have been variously described, are altered keratophyres. Above the volcanic band are two limestone-areas: one on the west, near Whiddon Down, and, separated by quartzose rocks, another limestone-area at Drewsteignton. Throughout the length of border considered, the top of the Calcareous Series is formed of grey shales, with hard rock-bands which pass upwards into the Upper Aluminous Series. The granite south of the Carboniferous border-rocks shows three separate intrusions, all from the same magma, but showing sufficient differences to separate them.—D. J. **Farquharson**: The geology of southern Guernsey. With the possible exception of some dykes of doubtful Palæozoic age, the whole of Guernsey consists of pre-Cambrian rocks—gneisses and schists in the south; unfossiliferous shales and grits at Pleinmont; and a series of intrusions in the north, which range from hornblende-gabbro through diorites and tonalites to granites with their accompanying dykes. These dykes not only pierce the last-named suite, but also the gneisses and grits of the south.

PARIS.

Academy of Sciences, November 26.—M. Albin Haller in the chair.—E. L. **Bouvier**: *Ormiscodes gregatus*, a moth the larvæ of which group together to build complex pouches. A description of the building habits of a new species of Ormiscodes found by M. Grisol in the neighbourhood of San Fernando d'Apure, Venezuela. The pouch is built in common, and may contain 10 to 12 cocoons. The name *Ormiscodes gregatus* is proposed for the species.—G. **Friedel**: The black inclusions contained in Cape diamonds. These inclusions have been regarded as graphite, but without clear proof. E. Cohen has shown in a large diamond of 80 carats that the inclusion was a flattened crystal of oligist, and has concluded that many inclusions, if not all, are oligist. The author regards these conclusions as too sweeping, and shows that in the case of a diamond in the University Museum at Strasbourg the inclusion was certainly not oligist, but was very probably graphite.—M. Aimé Cotton was elected a member of the section of general physics in the place of the late J. Violle.—Harald **Bohr**: The approximation of nearly periodic functions by trigonometrical summation.—Pierre **Humbert**: The confluences of Clausen's series.—Léon **Pomey**: Linear integro-differential equations with several variables.—René **Lagrange**: Systems connected with linear differential equations.—Paul **Sonnier**: Thin rectangular plates with edges resting on a fixed surface.—Ernest **Esclangon**: Gliding flight without motive power.—C. E. **Guye**: The motion of the gas in the electromagnetic rotation of the electric discharge. In the case where the action of the positive ions is alone concerned in imparting a movement of rotation to the gas, the observed velocity V can be put in the form

$$V = \frac{\epsilon H}{12\pi\sigma^2 Mm}\left[1 + \frac{3N}{M - N}\right],$$

where ϵ is the charge of the ion supposed equal to that of the electron, H the magnetic field producing the rotation, σ and m the radius and mass of the molecule or positive ion, M the total number of molecules, ionised or not, and N the number of positive ions contained in unit volume of the discharge. This expression allows the approximate deduction of N.—R. **Mesny** and P. **David**: Very short waves in wireless telegraphy. With very short wave-lengths it is possible to utilise parabolic mirrors so as to direct the bundle of radiations. The short waves are produced by an arrangement of two symmetrical triodes: waves of wave-length of 1·6 metres can be produced, and telephonic communications have been produced with these at a distance of two kilometres without using mirrors.—Paul **Woog**: The resistance to rupture, lateral compression and equilibrium, of monomolecular layers of various substances in thin films on water.—René **Audubret**: The influence of polarisation on photo-voltaic effects. The mechanism of the phenomenon. The results of the experiments described can be expressed in terms of the Nernst theory by saying that light acts on the electrodes by modifying the solution tension of metals, with an intensity and sense connected with the state of polarisation of the plate.—J. **Pouget** and D. **Chouchak**: The radioactivity of the mineral waters of Algeria.—A. **Lassieur**: An arrangement for electrolysis with graded potentials. The method of Sand and of A. Fischer is modified by replacing the potentiometer measurement by a millivoltmeter and a high resistance.—Camille **Matignon**: A new reaction for the preparation of strontium. Strontia is heated in an iron tube with silicon and the strontium condensed in the cool part of the tube.—M. **Faillebin**: The hydrogenation of certain ketones in the presence of pure or impure platinum black.—A. **Daucet**: The action of xanthydrol on semicarbazide, the substituted semicarbazides, the semicarbazones and benzoylhydrazine. The monoxanthylsemicarbazide is shown to possess the constitution $NH_2.NH.CO.NH.CH(C_6H_7)_2O$, the hydrazine radicle remaining free and capable of combining with aldehydes and ketones in the usual manner.—P. **Gaubert**: The optical properties of graphite and graphitic oxide. The index of refraction of graphite is between 1·93 and 2·07; the crystal is optically negative.—David **Rotman-Roman**: Contributions to the lithology of the Yemen; deep rocks and non-differentiated lode-bearing rocks.—Albert **Michel-Lévy**: Some eruptive rocks from the neighbourhood of Toulon (Var).—Léon **Bertrand** and Léonce **Joleaud**: The relations between the crystalline and sedimentary formations in the western part of Madagascar, between Betsiboka and Tsiribihina.—R. **Dongier**: Magnetic measurements carried out in Dauphiné, Savoie, and Bresse.—Beaulard **de Lenaizan**: The earthquake of November 19, 1923. This shock was recorded on the barograph at Montpellier at 3.40 A.M.—Lucien **Daniel**: New researches on the migration of inulin in grafts of Compositeæ.—A. **Guilliermond**: New observations on the evolution of the chondriome in the embryonic sac of the Liliaceæ.—P. **Lecomte du Noüy**: Meaning of the maximum fall of surface tension of the blood serum.—L. **Mercier** and Raymond **Poisson**: Contribution to the study of the atrophy of the wings and muscles of flight in the Forficulidæ.—Alain **Caillas**: The composition of propolis of bees. Propolis, or bee glue, contains 70 per cent. of resins and 30 per cent. of wax.—Louis **Boutan**: The two zones of external

epithelium of the mantle and their influence on the quality of the pearls in molluscs.—L. Fage and R. Legendre: The nuptial dances of some species of Nereis.—Boris Ephrussi: The action of a high temperature on the mitosis of segmentation of the eggs of the sea urchin.—Nicola Alberto Barbieri: Presence of the retina and absence of the optic nerves in anencephalic monsters.—R. Bazin: Certain coincidences of malignant neoplasms and their delay in appearance.—E. Lesné, L. de Gennes, and Ch. O. Guillaumin: Study of phosphating in cases of rickets and its variations under the influence of ultraviolet rays.—E. Wollman and J. A. Graves: Alexic hæmolysis and proteolysis.

Cape Town.

Royal Society of South Africa, October 17.—Dr. A. Ogg, president, in the chair.—K. H. Barnard: An example of adaptation in a South African isopod Crustacean. One of the most interesting inhabitants of the empty tubes of the reef-building polychaet worm, *Sabellaria capensis*, is an isopod Crustacean, allied to Eisothistos. This animal has evolved an elongate worm-like shape in strong contrast to the other members of the Isopoda. The "tail-fan" on the other hand is greatly enlarged, and when fully expanded fits the mouth of the worm-tube exactly.—S. H. Haughton and A. W. Rogers: The volcanic rocks south of Zuurberg. In the divisions of Steytlerville, Uitenhage, and Alexandria, the rocks extend through an area about 100 miles in length from east to west along the northern boundary fault of the Cretaceous beds and are continued southwards round the western end of the Cretaceous area, following it again towards the east on its southern side for 23 miles. The folded belt of rocks belonging to the Cape system and lower part of the Karroo system forms an incomplete "frame" defined by faults on the north, west, and partly on the south, within which there is a sunken area. This area consists of Cretaceous rocks lying unconformably upon an uneven surface of marls, sandstones, sandy tuffs, breccias, and basalts. This latter post-Ecca, pre-Cretaceous formation forms a syncline of post-Uitenhage date, and is unaffected by the intense folding and cleavage of the surrounding region. It can probably be correlated with part of the Stormberg series.—A. V. Duthie: Studies in the morphology of *Selaginella pumila*. Part III. The embryo. The megaspores of *Selaginella pumila*, which are shed towards the end of the year, lie dormant on the soil during the summer months and germinate after the early winter rains. Intra-sporal embryos can endure prolonged drying without losing their vitality. The embryo has a prominent foot with large haustorial cells which project into the non-septate storage cavity of the megaspore. The cotyledons do not develop simultaneously, nor are they strictly opposite each other. The first dichotomy of the axis, which takes place at the level of the cotyledons, gives rise to two branches, one of which grows erect; the other develops into a very short horizontal rhizome with branches alternately right and left. The number of cones found on adult plants varied from 1 to 160. The sporophytes are greatly modified by conditions of environment. *S. pumila* possesses a number of characters which are very suggestive of the tree-like Lycopods of the Palæozoic. Its closest relative is the Australian species, *S. Preissiana*.—J. R. Sutton: On the genesis of diamond. The various known forms of diamond are attributable to growth only. Crystallisation was not necessarily at a high temperature, and may have been preceded by a condition of plasticity in the carbon. Diamond was deposited from a carbon solvent within cavities, the contour of which determined its final form and habit, in a solid or solidifying matrix.—J. S. v. d. Lingen: On the action of some fluorescent antiseptics in the dark. (Preliminary note.)

Brussels.

Royal Academy of Belgium, January 6.—M. Aug. Lameere in the chair.—El. and Em. Marchal: The "Homothallism" of some Ascomycetes. In cultures of single spores the following Ascomycetes produce normally fertile perithecia: *Hypocopra fimicola*, *H. macrospora*, *Sordaria tetraspora*, *Philocopra setosa*, *P. curvicolla*, *Sporormia intermedia*, *Choetomium elatum*. Hence these species should be considered as "homothallic."—V. Van Straelen and M. E. Denaeyer: The fossil eggs of the Upper Cretacean of Rognac in Provence. These fossils have been submitted to a palæontological and mineralogical study. It is not possible to determine with precision the origin of the eggs, but they present more analogies with birds' eggs than with those of reptiles.—P. Bruylants and J. Gevaert: Contribution to the study of the reaction between organo-magnesium compounds and nitriles. Vinyl-acetic nitrile. Vinyl-acetonitrile with ethylmagnesium bromide gives dipropenyl, two isomers of crotonitrile, and two polymers of the latter.—P. Bruylants: The action of organo-magnesium compounds on glutaric nitrile.

February 3.—M. Ch. J. de la Vallée-Poussin in the chair.—Clément Servais: A group of three tetrahedra.—C. de la Vallée-Poussin: The movement of a heavy homogeneous solid of revolution fixed by a point on its axis.—Th. de Donder: The physical interpretation of general relativity.—Lucien Godeaux: Cyclic involutions of fourth order belonging to a surface of genus one.

March 3.—M. Ch. J. de la Vallée-Poussin in the chair.—Th. de Donder: The physical interpretation of general relativity.—Marcel Winants: Intersecants and tangentials.—Victor Van Straelen: The systematic position of some decapod Crustacea of the Cretacean epoch.

April 7.—M. Ch. J. de la Vallée-Poussin in the chair.—Th. de Donder: Remarks on the Einstein gravific.—P. Stroobant: (1) The National Astronomical Committee. An account of the work carried out during the years 1921 and 1922. (2) National Committee of Geodesy and Geophysics. An account of the work done in 1921 and 1922.—Jean Morelle: The cytoplasmic constituents in the pancreas and their rôle in secretion.—Laure Willem: Researches on the aerial respiration of the Amphibia.

May 8.—M. Léon Fredericq in the chair.—G. Cesaro: The equiorientation and similitude of the ellipse of inertia and Steiner's ellipse in the triangle. The Steiner ellipsoids and ellipsoid of inertia of the tetrahedron.—P. Fourmarier: The presence of oolitic pebbles in the Tertiary gravels of Cokaifagne (Sart-lez-Spa).—H. Philippot: The comparison of time by wireless telegraphy in 1922. A detailed study of the results obtained over one year at the Observatories of Algiers, Edinburgh, Greenwich, and Uccle on the observations of the time signals sent daily from Paris by wireless telegraphy.

June 2.—M. Ch. J. de la Vallée-Poussin in the chair.—P. Fourmarier: The supposed glacial phenomena of the Baraque Michel. The author concludes that it is improbable that the plateau of the Baraque Michel has been covered by a glacier.—Laure Willem: Aerial respiration in the Amphibia (2).

July 7.—M. Ch. J. de la Vallée-Poussin in the chair.—Jean Massart: Researches on the lower organisms. (VIII.) Reflexes in Polyporus.—Cl. Servais: The

geometry of the triangle and the tetrahedron.—Francis **Meunier**: The electrolytic overvoltage of hydrogen. A short account of the present knowledge of the phenomena of overvoltage, with an experimental study of the overvoltage of hydrogen on platinum, lead, molybdenum, and tungsten. It has been found that the magnitude of the cathode surface is without influence, the overvoltage increasing as the concentration of the electrolyte diminishes. The fluorine ion, added in small proportions, reduces the overvoltage.—A. **d'Hooghe**: The mechanism of the reduction of oxide of zinc.

August 4.—M. Ch. de la Vallée-Poussin in the chair.—Th. **de Donder**: The fundamental formula of the new gravific.—P. **Fourmarier**: The southern extension of the gap of Theux.—Fréd. **Swarts**: The catalytic hydrogenation of organic compounds containing fluorine. Meta-trifluorcresol treated with hydrogen in the presence of platinum black gives trifluormethyl-cyclo-hexanol, trifluormethyl-cyclohexane, and water. The velocity of the reaction was studied.—Edouard **Herzen**: A simple method of obtaining the stationary orbits of Bohr in the hydrogen spectrum.—L. **Godeaux**: The cyclic involutions of the fourth order belonging to a surface of genus one (2).—G. **Lemaitre**: A property of the Hamiltonians of a multiplier.—Laure **Willem**: Researches on the aerial respiration of the Amphibia (3).

Official Publications Received.

Memoirs of the Department of Agriculture in India. Chemical Series, Vol. 7, No. 3: A Preliminary Note on the Decomposition of Calcium Cyanamide in South Indian Soils. By Dr. Roland V. Norris, B. Viswanath, and C. V. Ramaswami Ayyar. Pp. 55-75. (Calcutta: Thacker, Spink and Co.; London: W. Thacker and Co.) 12 annas; 1s.

Bulletin of the American Museum of Natural History. Vol. 48, Art. 17: New Fossil Mammals from the Pliocene of Sze-Chuan, China. By W. D. Matthew and Walter Granger. Pp. 563-598. Vol. 48, Art. 18: The Problem of the Uintatherium Molars. By Horace Elmer Wood. Pp. 599-604. (New York.)

Department of Agriculture, Madras. Bulletin No. 84: A Soil Survey of the Periyar Tract. By Dr. Roland V. Norris, M. R. Ramaswami Sivan, and S. Kasinatha Ayyar. Pp. 6+10 maps. (Madras: Government Press.) 1.14 rupees.

Meteorology in Mysore for 1922: Being the Results of Observations at Bangalore, Mysore, Hassan, and Chitaldrug. Thirtieth Annual Report, by C. Seshachar. Pp. iii+15. (Bangalore: Government Press.)

Mysore Government: Meteorological Department. Report of Rainfall Registration in Mysore for 1922. By C. Seshachar. Pp. xvii+35. (Bangalore: Government Press.)

Publications of the South African Institute for Medical Research. No. 16: On the Effects of Cold on the Vitality of certain Cysticerci and Echinococci in Meat kept under Commercial Conditions of Freezing in Johannesburg. By Dr. Annie Porter. Pp. 49. (Johannesburg.) 5s.

The Indian Forest Records. Vol. 9, Part 9: Note on the Work of Extraction of Broad Gauge Sleepers from Nepal. By J. V. Collier. Pp. 349-357+15 plates. (Delhi: Government Central Press.) 1.11 rupees.

Geological Survey, Canada. Index to Separate Reports 1906–1910 and Summary Reports 1905–1916. Compiled by F. J. Nicolas. Pp. 305. (Ottawa: F. A. Acland.)

Canada. Department of Mines: Geological Survey. Summary Report, 1922, Part B. Pp. 135B. Summary Report, 1922, Part C. Pp. 91C. (Ottawa: F. A. Acland.)

Tide Levels and Datum Planes on the Pacific Coast of Canada; from Determinations by the Tidal and Current Survey up to the Year 1923. (Published by the Department of Marine and Fisheries.) Pp. 68. (Ottawa: F. A. Acland.)

Transactions of the Astronomical Observatory of Yale University. Vol. 3, Part 2: Trial of the Loomis Memorial Telescope for Stellar Photometry; with Determinations of the Light Curves of the RR Ceti ($1^h\ 27^m$) and of VV Orionis ($5^h\ 28^m$). Pp. 51-80. (New Haven.)

The South-Eastern Naturalist: Being the Twenty-eighth Volume of Transactions of the South-Eastern Union of Scientific Societies, including the Proceedings at the Twenty-eighth Annual Congress, held at Maidstone, 1923. Edited by Edward A. Martin. Pp. lxxxii+94+8 plates. (London.) 5s. net.

International Geodetic and Geophysical Union (Union Géodésique et Géophysique Internationale): Section of Terrestrial Magnetism and Electricity. Bulletin No. 3: Transactions of Rome Meeting, May, 1922. Edited by Louis A. Bauer. Pp. vii+181. (Baltimore, Md.: Johns Hopkins Press.) 3.50 dollars.

Journal of the Marine Biological Association of the United Kingdom. New Series, Vol. 13, No. 1, December. Pp. 313. (Plymouth.) 10s. net.

Bulletin of the National Research Council. Vol. 6, Part 5, No. 36: Catalogue of Published Bibliographies in Geology, 1896–1920. Compiled by Edward B. Mathews. Pp. 228. (Washington, D.C.: National Academy of Sciences.) 2.50 dollars.

Nineteenth Report, State Entomologist of Minnesota to the Governor. By A. G. Ruggles. Pp. 151. (St. Paul, Minn.: Agricultural Experiment Station, University Farm.)

Annuaire pour l'an 1924, publié par le Bureau des Longitudes. Pp. viii+658+A9+B26+C17+D10+E26+F72. (Paris: Gauthier-Villars et Cie.) 6 francs.

Diary of Societies.

SATURDAY, DECEMBER 29.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir William Bragg: Concerning the Nature of Things: The Nature of Gases (Juvenile Lectures (2)).

MONDAY, DECEMBER 31.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 3.30.—Mrs. Charles Hose: Boat Journeys in Sarawak (Lecture for Young People).

TUESDAY, JANUARY 1.

CONFERENCE OF EDUCATIONAL ASSOCIATIONS (at University College), at 2.30.—Sir W. Henry Hadow: The Claims of Scholarship (Presidential Address).

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir William Bragg: Concerning the Nature of Things: The Nature of Liquids (Juvenile Lectures (3)).

MONTESSORI SOCIETY (at University College), at 6.—Miss Barbara Low: The Value of Psycho-Analysis to the Educator.

WEDNESDAY, JANUARY 2.

ROYAL SOCIETY OF ARTS, at 3.—Prof. W. A. Bone: Fire and Explosions (Dr. Mann Juvenile Lectures (1)).

SCHOOL NATURE STUDY UNION (at University College), at 3.—Sir Richard Gregory: The Sun and Stars.

PHYSICAL SOCIETY OF LONDON AND OPTICAL SOCIETY (Annual Exhibition, at the Imperial College of Science and Technology), 3 to 6 and 7 to 10. —At 4.—H. B. Grylls: The Heape and Grylls Rapid Cinema Machine.—At 8.—Sir Richard Paget, Bart.: The Nature and Artificial Reproduction of Human Speech (Vowel Sounds).

ROYAL SOCIETY OF MEDICINE (Surgery Section), at 5.30.—D. Fitzwilliams: A Scientific Method of Removing Foreign Bodies.—A. G. T. Fisher: The Pathology and Treatment of Internal Derangements of the Knee-joint.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—R. H. Barfield: Some Experiments on the Screening of Radio Receiving Apparatus.

ROYAL MICROSCOPICAL SOCIETY (Biological Section), at 7.30.—B. K. Das: The Habits of some Indian Fishes.

THURSDAY, JANUARY 3.

GEOGRAPHICAL ASSOCIATION (at Birkbeck College), at 9.30 A.M.—L. MacD. Robison: Ceylon.—At 11.30 A.M.—Sir Richard Gregory: British Climate in Historic Times (Presidential Address).—At 2.—Joint Conference with the Royal Meteorological Society and the Science Masters' Association. Subjects for Discussion: The Place of Meteorological Observations in the School Course—The Teaching of Meteorology and Climatology in Schools.—At 5.30.—Prof. E. de Martonne: A Study of Transylvania.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir William Bragg: Concerning the Nature of Things: The Nature of Crystals—the Diamond (Juvenile Lectures (4)).

PHYSICAL SOCIETY OF LONDON AND OPTICAL SOCIETY (Annual Exhibition, at Imperial College of Science and Technology), 3 to 6 and 7 to 10.—At 4.—Sir Richard Paget, Bart: The Nature and Artificial Reproduction of Human Speech (Vowel Sounds).—At 8.—H. B. Grylls: The Heape and Grylls Rapid Cinema Machine.

INCORPORATED BRITISH ASSOCIATION FOR PHYSICAL TRAINING (at University College), at 5.30.—Major H. J. Selby: The Mental, Moral, and Physical Health of a Nation.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—Dr. S. P. Smith: Railway Electrification in Foreign Countries.

FRIDAY, JANUARY 4.

GEOGRAPHICAL ASSOCIATION (at Birkbeck College), at 10.30 A.M.—Conference on The Teaching of Railway Geography.—At 2.30.—Annual Business Meeting.

EUGENICS EDUCATION SOCIETY AND LING ASSOCIATION (at University College), at 3.—Mrs. Hodson: The Teaching of Hygiene and Racial Progress.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 3.30.—Mrs. Julia Henshaw: Camping in the Kootenay, British Columbia (Lecture for Young People).

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Pictorial Group Meeting.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—L. Manico: Economy of Fuel by Removal of Soot from Boiler Tubes.

PHILOLOGICAL SOCIETY (at University College), at 8.—Prof. S. Boyanus: Russian and English Phonetics.

SATURDAY, JANUARY 5.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir William Bragg: Concerning the Nature of Things: The Nature of Crystals—Ice and Snow (Juvenile Lectures (5)).

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—Sir David Prain: Gilbert White and Moral History.

Recent Scientific and Technical Books.

Volumes marked with an asterisk have been received at "NATURE" *Office.*

Mathematics

Dingler, H. Das Problem des absoluten Raumes in historisch-kritischer Behandlung. 8vo. Pp. 50. (Leipzig: S. Hirzel, 1923.) Grundzahl: 1.50 marks.

Eudoxe. Géométrie pure et géométrie descriptive. 8vo. Pp. 32. (Paris: A. Blanchard, 1923.) 2 francs.

Feldman, W. M. Biomathematics: being the Principles of Mathematics for Students of Biological Science. Cr. 8vo. Pp. xix + 398. (London: C. Griffin and Co., Ltd., 1923.) 21*s.* net.*

Fournier, Georges. La Relativité vraie et la gravitation universelle. Demy 8vo. Pp. viii + 130. (Paris: Gauthier-Villars et Cie, 1923.) 7 francs.*

Gauss, C. F. Carl Friedrich Gauss' Werke. Zehnten Bandes Abt. 2. Abhandlung IV. Stäckel: Gauss als Geometer. (Leipzig und Berlin: B. G. Teubner, 1923.) 6*s.* 5*d.*

Gibbs, R. W. M. Constructive Arithmetical Exercises. Cr. 8vo. Part 2. Pp. 277. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1923.) 3*s.* 6*d.* net.

Gillmer, M. Trigonometrie und Stereometrie. (Kollegienhefte, Band 18.) 8vo. Pp. vi + 226. (Leipzig: S. Hirzel, 1922.) 5 Schw. francs.

Küster, F. W., Begründet von. Logarithmische Rechentafeln für Chemiker, Pharmazeuten, Mediziner und Physiker. Nach dem gegenwärtigen Stande der Forschung bearbeitet von A. Thiel. 27-29 verbesserte und vermehrte Auflage. Pp. 132. (Berlin und Leipzig: W. de Gruyter und Co., 1923.)

Loney, S. L. The Elements of Coordinate Geometry. Cr. 8vo. Part 2: Trilinear Coordinates, etc. Pp. viii + 228. (London: Macmillan and Co., Ltd., 1923.) 6*s.**

Mie, Gustav. Die Einstein'sche Gravitationstheorie: Versuch einer allgemeinverständlichen Darstellung der Theorie. Zweite Auflage. Large 8vo. Pp. iv + 69. (Leipzig: S. Hirzel, 1923.) 1.20 Schw. francs.

Muir, Sir Thomas. The Theory of Determinants in the Historical Order of Development. Demy 8vo. Vol. 4: The Period 1880 to 1900. Pp. xxxi + 508. (London: Macmillan and Co., Ltd., 1923.) 40*s.* net.*

Onnen. Kreisevolventen und ganze algebraische Funktionen. (Math.-physik. Bibliothek, Band 51.) (Leipzig und Berlin: B. G. Teubner, 1923.) 9*d.*

Tropfke, J. Geschichte der Elementarmathematik in systematischer Darstellung mit besonderer Berücksichtigung der Fachwörter. Roy. 8vo. Vierter Band: Ebene Geometrie. Zweite, verbesserte und sehr vermehrte Auflage. Pp. iii + 238. (Berlin und Leipzig: W. de Gruyter und Co., 1923.) Grundzahl: 7.50 marks.

Whipple, George C. Vital Statistics: an Introduction to the Science of Demography. Second edition. Fcap. 8vo. Pp. xiv + 579. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923.) 20*s.* net.*

Physics: Electrical Engineering

Alexander, E. Wireless. (Drane's A B C Series.) 18mo. Pp. 109. (London: Drane's, 1923.) 1*s.* 6*d.* net.

Astruc, Marcel. Magnéto et allumage. Pp. 215. (Paris: Libr. Berger-Levrault, 1923.)
